A termination argument

Consider a cyclic arrangement of a set of integer variables. Any pair \( x, y \) of these variables such that \( x \) is the clockwise neighbour of \( y \) enables a "move" if \( x < y \) : the move then consists of adding 1 to \( x \) and subtracting 1 from \( y \), i.e. in guarded-command notation

\[
(x < y \rightarrow x, y := x+1, y-1)
\]

We leave for the reader to prove

\[
(1) \quad \text{(no move is possible)} \equiv \text{(all variables have the same value)}
\]

A game consists of an initialization of the variables, followed by a sequence of moves until no move is possible. Since a move leaves the number of variables and also the sum of their values unchanged, we conclude

\[
(2) \quad \text{in a game, the average of the values is constant.}
\]

(In passing, we note that if this average is not an integer, the game therefore fails to terminate.)
A slightly more sophisticated theorem is

(3) an enabled move sooner or later
takes place.

Proof Consider an enabled move, i.e. a
pair \( x, y \) such that \( x \prec y \). Rearrange
the variables in a string, starting with
\( x \) and ending with \( y \), by "cutting"
the cycle between \( x \) and \( y \), and then
"straightening" it. The other moves then
correspond to the pairs that are neighbours
in the string. Of those moves now observe
(i) that — since each of them moves
the centre of gravity of the values over a
fixed amount towards \( y \) — only a finite
number of them can take place before
(the values form an ascending sequence and)
no more of them are possible, and
(ii) that none of them falsifies \( x \prec y \).
Hence the occurrence of an enabled move
is not be postponed indefinitely. (End
of Proof.)

Looking for (a component of) a variant
function, there is no point in looking
at the sum of the values, since that
sum is constant. However, the sum \( S \)
of the squares of the values — obviously
bounded from below — might be of inter-
est. We observe for the change $\Delta S$ of $S$ under move (0)

$$\Delta S = \{ \text{def. of } S \text{ and of move (0)} \}$$

$$= (x+1)^2 + (y-1)^2 - (x^2 + y^2)$$

$$= \{ \text{algebra} \}$$

$$= 2 \cdot (x+1 - y)$$

that is, there are two kinds of moves:

(4) $x+1 < y \rightarrow x, y := x+1, y-1$

under which $S''$ is decreased by at least 2, and -after simplification-

(5) $x+1 = y \rightarrow x, y := y, x$

under which $S$ remains constant: for $S$ to decrease, $x$ and $y$ should differ at least 2.

For the rest of this note, we confine our attention to games such that after initialization the average of the values of the variables is integer; from (2) we conclude that this then holds all through the game. For such a game we can assert

(6) if a move is possible, maximum and minimum differ by at least 2.
Proof If a move is possible —see (1)— not all values are equal, i.e. the maximum exceeds the average, which exceeds the minimum. All three being integer, the maximum exceeds the minimum by at least 2. (End of Proof.)

From (6) we conclude

(7) if a move is possible, sooner or later $S'$ is decreased.

Proof For any two distinct variables $p$ and $q$ we define as "the separators" the variables situated on the cycle between $p$ and $q$ on the clockwise path from $p$ to $q$. Thanks to (6) we can choose $p$ and $q$ such that

(i) $p - q \geq 2$

(ii) for any separator $s$: $p > s \land s > q$ .

We observe that (i) and (ii) are maintained by moves among the variables on the counter-clockwise path from $p$ to $q$ ($p$ may grow and $q$ may shrink, but that is okay), and also by moves on pairs $s,s'$ of separators.

If there are separators, the moves on $s,p$ and on $q,s$ are enabled because of (ii) ; because of (3), sooner or
later, one of them occurs. If it is of type (4), \( S \) is decreased. If it is of type (5), we reduce the number of separators by 1 and restore (i) and (ii) by moving \( p \) (clockwise) or \( q \) (counter-clockwise) over 1 position.

Finally, if there are no separators left, the move on the pair \( q, p \) is enabled; because of (i), this move is of type (4) and because of (3), sooner or later it will decrease \( S \). (End of Proof.)

And thus we have established that if the average value is integer, the game terminates (and such was our goal).

The above has been written in reaction to a paper I had been asked to referee.
