Foundations of Computer Security Lecture 69: PGP Key Management

> Dr. Bill Young Department of Computer Sciences University of Texas at Austin

PGP makes use of four types of keys: one-time session symmetric keys, public keys, private keys, passphrase-based symmetric keys. Session keys: used once and generated for each new message Public keys: used in asymmetric encryption Private keys: also used in asymmetric encryption Passphrase-based keys: used to protect private keys A single user can have multiple public/private key pairs. Each session key is associated with a single message and used only once. Key size depends on the chosen encryption algorithm E; e.g. CAST-128: 128 bits, 3DES: 168-bits, etc.

The encryption algorithm E is used to generate a new *n*-bit key from a previous session key and two n/2-bit blocks generated based on user keystrokes, including keystroke timing. The two blocks are encrypted using E and the previous key, and combined to form the new key. For new RSA keys, an odd number n of sufficient size (usually > 200 bits) is generated and tested for primality. If it is not prime, then repeat with another randomly generated number, until a prime is found.

Primes appear in the neighborhood of *n* about every $ln(n) = lg_e(n)$ numbers. Since we can exclude even numbers, to find a prime of around 200 bits, it takes about $ln(2^{200})/2 = 70$ tries.

This is an expensive operation, but performed relatively infrequently.

The private key is stored encrypted with a user-supplied passphrase:

- The user selects a passphrase for encrypting private keys.
- When a new public/private key pair is generated, the system asks for the passphrase. Using SHA-1, a 160-bit hash code is generated from the passphrase, which is discarded.
- The private key is encrypted using CAST-128 with 128 bits of the hash code as key. The key is then discarded.

Whenever the user wants to access the private key, he must supply the passphrase.

- PGP uses four kinds of keys: session keys, public and private keys, and passphrase generated keys.
- Public / private key pairs are the most expensive to generate.
- Since the security of the system depends on protecting private keys, these are encrypted using a passphrase system.
