Viewing and Modeling

Don Fussell
Computer Science Department
The University of Texas at Austin

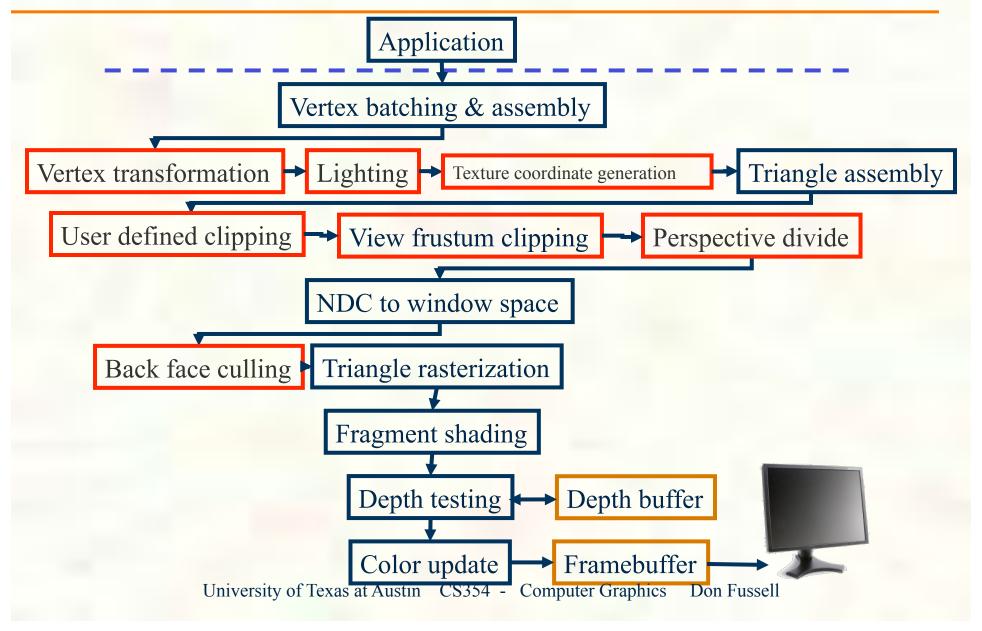

A Simplified Graphics Pipeline

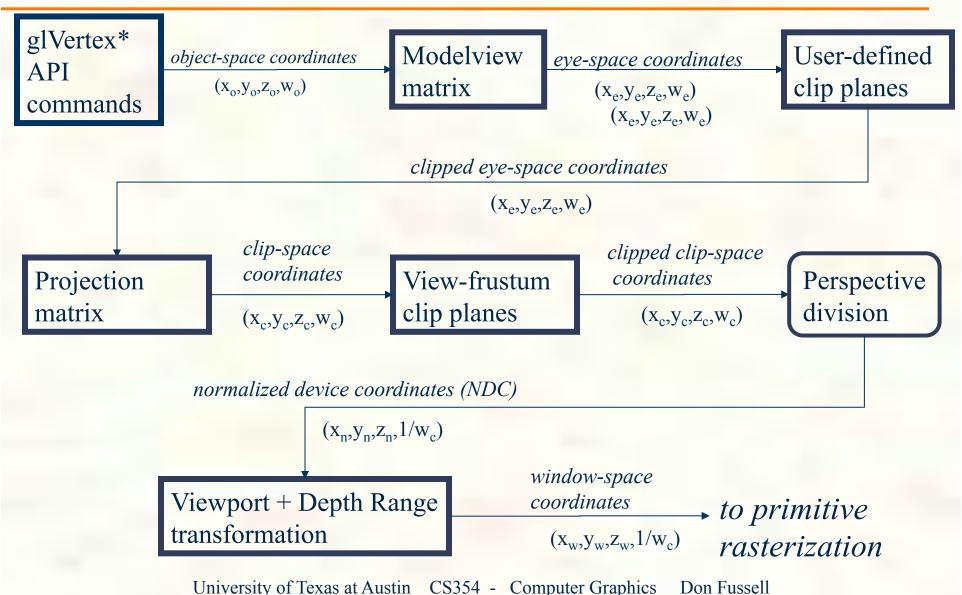

A few more steps expanded

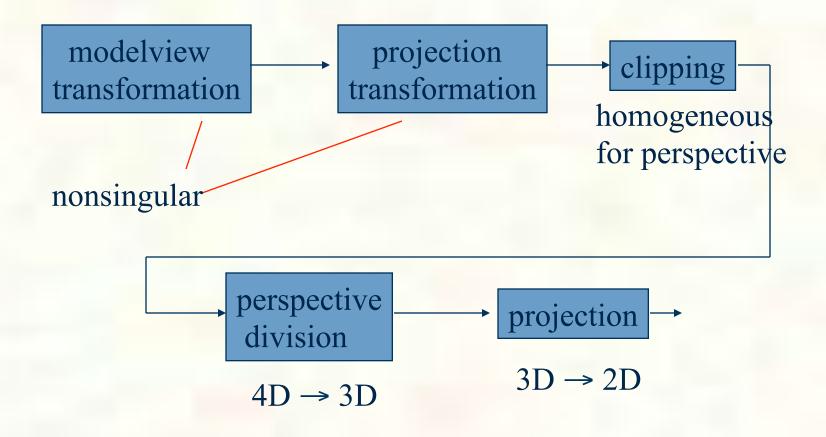

Conceptual Vertex Transformation

Pipeline View

Computer Viewing

- There are three aspects of the viewing process, all of which are implemented in the pipeline,
 - Positioning the camera
 - Setting the model-view matrix
 - Selecting a lens
 - Setting the projection matrix
 - Clipping
 - Setting the view volume

The World and Camera Frames

- When we work with representations, we work with ntuples or arrays of scalars
- Changes in frame are then defined by 4 x 4 matrices
- In OpenGL, the base frame that we start with is the world frame
- Eventually we represent entities in the camera frame by changing the world representation using the model-view matrix
- Initially these frames are the same (M=I)

Vertex Transformation

- Object-space vertex position transformed by a general linear projective transformation
 - Expressed as a 4x4 matrix

$$\begin{bmatrix} x_c \\ y_c \\ z_c \\ w_c \end{bmatrix} = \begin{bmatrix} m_0 & m_4 & m_8 & m_{12} \\ m_1 & m_5 & m_9 & m_{13} \\ m_2 & m_6 & m_{10} & m_{14} \\ m_3 & m_7 & m_{11} & m_{15} \end{bmatrix} \begin{bmatrix} x_o \\ y_o \\ z_o \\ w_o \end{bmatrix}$$

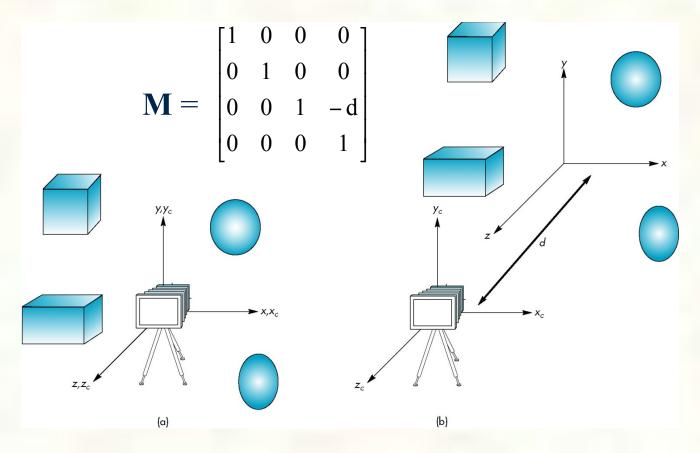

The OpenGL Camera

- In OpenGL, initially the object and camera frames are the same
 - Default model-view matrix is an identity
- The camera is located at origin and points in the negative z direction
- OpenGL also specifies a default view
 volume that is a cube with sides of length 2
 centered at the origin
 - Default projection matrix is an identity

Moving the Camera

If objects are on both sides of z=0, we must move camera frame

University of Texas at Austin CS354 - Computer Graphics Don Fussell

Moving the Camera Frame

- If we want to visualize object with both positive and negative z values we can either
 - Move the camera in the positive z direction
 - ■Translate the camera frame
 - Move the objects in the negative z direction
 - ■Translate the world frame
- Both of these views are equivalent and are determined by the model-view matrix
 - Want a translation (glTranslatef(0.0,0.0,-d);)
 - = d > 0

Translate Transform

- Prototype
 - ■glTranslatef(GLfloat x, GLfloat y, GLfloat z)
- Post-concatenates this matrix

$$\begin{bmatrix} 1 & 0 & 0 & x \\ 0 & 1 & 0 & y \\ 0 & 0 & 1 & z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

glTranslatef Matrix

- Modelview specification
 - glLoadIdentity();
 glTranslatef(0,0,-14)
 - x translate=0, y translate=0, z translate=-14
 - Point at (0,0,0) would move to (0,0,-14)
 - Down the negative Z axis
- Matrix

the translation vector

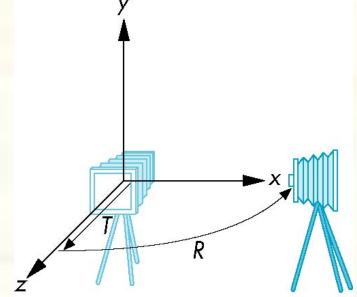

$$\begin{bmatrix} 1 & 0 & 0 & x \\ 0 & 1 & 0 & y \\ 0 & 0 & 1 & z \\ 0 & 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

General Camera Motion

We can move the camera to any desired position by a sequence of rotations and translations

- Example: side view
 - Rotate the camera
 - Move it away from origin
 - Model-view matrix C = TR

OpenGL code

Remember that last transformation specified is first to be applied

```
glMatrixMode(GL_MODELVIEW)
glLoadIdentity();
glTranslatef(0.0, 0.0, -d);
glRotatef(90.0, 0.0, 1.0, 0.0);
```

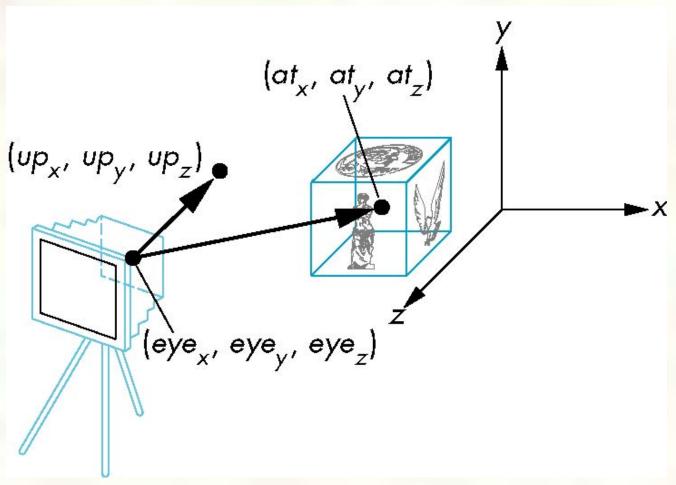

A Better Viewing Matrix

- "Look at" Transform
 - Concept
 - Given the following
 - a 3D world-space "eye" position
 - a 3D world-space center of view position (looking "at"), and
 - an 3D world-space "up" vector
 - Then an affine (non-projective) 4x4 matrix can be constructed
 - For a view transform mapping world-space to eye-space
- A ready implementation
 - The OpenGL Utility library (GLU) provides it
 - gluLookAt(GLdouble eyex, GLdouble eyey, GLdouble eyez, GLdouble atx, GLdouble atz, GLdouble atz, GLdouble upx, GLdouble upy, GLdouble upz);

Primary OpenGL libraries
Link with —lglut for GLUT
Link with —lGLU for GLU
Link with —lGL for OpenGL

gluLookAt(eyex, eyey, eyez, atx, aty, atz, upx, upy, upz)

University of Texas at Austin CS354 - Computer Graphics Don Fussell

"Look At" in Practice

- Consider our prior view situation
 - Instead of an arbitrary view...
 - ...we just translated by 14 in negative Z direction
 - \blacksquare glTranslatef(0,0,14)
- What this means in "Look At" parameters
 - \blacksquare (eyex,eyey,eyez) = (0,0,14)
 - \blacksquare (atx,aty,atz) = (0,0,0)
 - (upx,upy,upz) = (0,1,0)

Not surprising both are "just translates in Z" since the "Look At" parameters already have use looking down the negative Z axis

glTranslatef(0,0,-14)

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Same matrix; same transform

gluLookAt(0,0,14, 0,0,0, 0,1,0)

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

The "Look At" Algorithm

Vector math

- Z = eye at
- \blacksquare Z = normalize(Z) /* normalize means Z / length(Z) */
- Y = up
- $X = Y \times Z$ /* × means vector cross product! */
- $Y = Z \times X$ /* orthgonalize */
- \blacksquare X = normalize(X)
- \blacksquare Y = normalize(Y)

■ Then build the following affine 4x4 matrix

$$\begin{bmatrix} X_x & X_y & X_z & -X \bullet eye \\ Y_x & Y_y & Y_z & -Y \bullet eye \\ Z_x & Z_y & Z_z & -Z \bullet eye \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

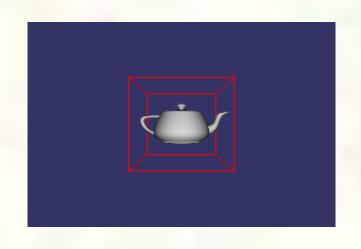

Warning: Algorithm is prone to failure if normalize divides by zero (or very nearly does)

So

- 1. Don't let Z or up be zero length vectors
- 2. Don't let Z and up be coincident vectors

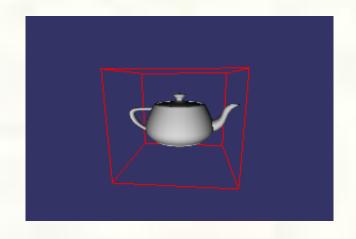

"Look At" Examples

```
gluLookAt(0,0,14, // eye (x,y,z)
0,0,0, // at (x,y,z)
0,1,0); // up (x,y,z)
```

Same as the glTranslatef(0,0,-14) as expected

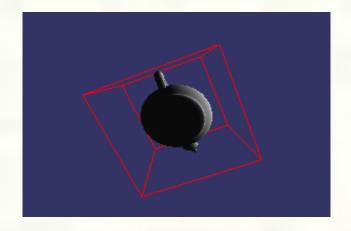

```
gluLookAt(1,2.5,11, // eye (x,y,z)
0,0,0, // at (x,y,z)
0,1,0); // up (x,y,z)
```

Similar to original, but just a little off angle due to slightly perturbed eye vector

"Look At" Major Eye Changes

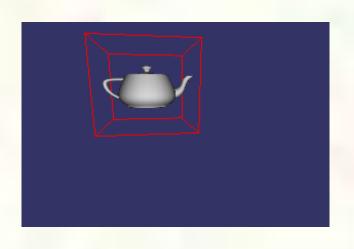

```
gluLookAt(-2.5,-11,1, // eye (x,y,z)
0,0,0, // at (x,y,z)
0,1,0); // up (x,y,z)
Eye is "below" the scene
```

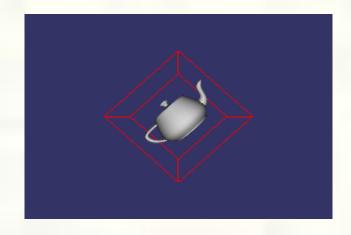

"Look At" Changes to AT and UP

```
gluLookAt(0,0,14, // eye (x,y,z)
2,-3,0, // at (x,y,z)
0,1,0); // up (x,y,z)
```

Original eye position, but "at" position shifted

```
gluLookAt(0,0,14, // eye (x,y,z)
0,0,0, // at (x,y,z)
1,1,0); // up (x,y,z)
```

Eye is "below" the scene

The LookAt Function

- The GLU library contains the function gluLookAt to form the required modelview matrix through a simple interface
- Note the need for setting an up direction
- Still need to initialize
- Can concatenate with modeling transformations
- Example: isometric view of cube aligned with axes

```
glMatrixMode(GL_MODELVIEW):
glLoadIdentity();
gluLookAt(1.0, 1.0, 1.0, 0.0, 0.0, 0.0, 0., 1.0. 0.0);
```

Other Viewing APIs

- The LookAt function is only one possible API for positioning the camera
- Others include
 - View reference point, view plane normal, view up (PHIGS, GKS-3D)
 - Yaw, pitch, roll
 - ■Elevation, azimuth, twist
 - Direction angles

Two Transforms in Sequence

OpenGL thinks of the projective transform as really two 4x4 matrix transforms

University of Texas at Austin CS354 - Computer Graphics Don Fussell

Modelview-Projection Transform

- Matrixes can associate (combine)
 - Combination of the modelview and projection matrix = modelview-projection matrix
 - ■or often simply the "MVP" matrix

$$\begin{bmatrix} MVP_0 & MVP_4 & MVP_8 & MVP_{12} \\ MVP_1 & MVP_5 & MVP_9 & MVP_{13} \\ MVP_2 & MVP_6 & MVP_{10} & MVP_{14} \\ MVP_3 & MVP_7 & MVP_{11} & MVP_{15} \end{bmatrix} = \begin{bmatrix} P_0 & P_4 & P_8 & P_{12} \\ P_1 & P_5 & P_9 & P_{13} \\ P_2 & P_6 & P_{10} & P_{14} \\ P_3 & P_7 & P_{11} & P_{15} \end{bmatrix} \begin{bmatrix} MV_0 & MV_4 & MV_8 & MV_{12} \\ MV_1 & MV_5 & MV_9 & MV_{13} \\ MV_2 & MV_6 & MV_{10} & MV_{14} \\ MV_2 & MV_6 & MV_{10} & MV_{14} \\ MV_3 & MV_7 & MV_{11} & MV_{15} \end{bmatrix}$$

Matrix multiplication

is **associative** (but not commutative) A(BC) = (AB)C, but ABC\neq CBA

concatenation is 64 Multiply-Add operations, done by OpenGL driver

Specifying the Transforms

- Specified in two parts
- First the projection
 - glMatrixMode(GL_PROJECTION);
 - glLoadIdentity();
 - glFrustum(-4, +4, // left & right -3, +3, // top & bottom 5, 80); // near & far

Second the model-view

- glMatrixMode(GL_MODELVIEW);
- glLoadIdentity();
- \blacksquare glTranslatef(0, 0, -14);
 - So objects centered at (0,0,0) would be at (0,0,-14) in eye-space

Resulting projection matrix

[1.25	0	0	0]
0	1.667	0	0
0	0	-1.1333	-10.667
0	0	-1	0

Resulting modelview matrix

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Modelview-Projection Matrix

Transform composition via matrix multiplication

$$\begin{bmatrix} 1.25 & 0 & 0 & 0 \\ 0 & 1.667 & 0 & 0 \\ 0 & 0 & -1.1333 & -10.667 \\ 0 & 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

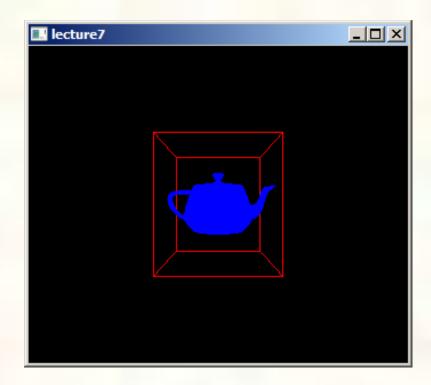

$$= \begin{bmatrix} 1.25 & 0 & 0 & 0 \\ 0 & 1.667 & 0 & 0 \\ 0 & 0 & -1.1333 & 5.2 \\ 0 & 0 & -1 & 14 \end{bmatrix}$$

Resulting modelview-projection matrix

Now Draw Some Objects

- Draw a wireframe cube
 - glColor3f(1,0,0); // red
 - glutWireCube(6);
 - 6x6x6 unit cube centered at origin (0,0,0)
- Draw a teapot in the cube
 - glColor3f(0,0,1); // blue
 - glutSolidTeapot(2.0);
 - \blacksquare centered at the origin (0,0,0)
 - handle and spout point down the X axis
 - top and bottom in the Y axis
- As we'd expect given a frustum transform, the cube is in perspective
 - The teapot is too but more obvious to observe with a wireframe cube

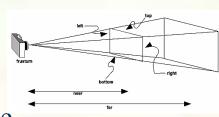

What We've Accomplished

Simple perspective

- With glFrustum
- Establishes how eye-space maps to clip-space

■ Simple viewing

- With glTranslatef
- Establishes how world-space maps to eye-space

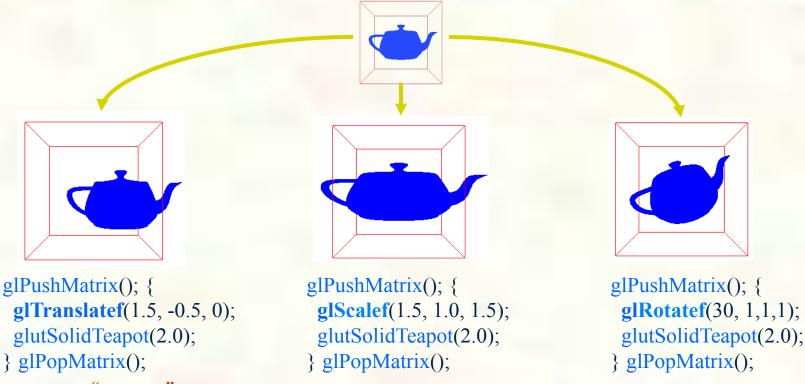

- All we really did was "wheel" the camera 14 units up the Z axis
- No actual "modeling transforms", just viewing
 - Modeling would be rotating, scaling, or otherwise transform the objects with the view
 - Arguably the modelview matrix is really just a "view" matrix in this example

Some Simple Modeling

- Try some modeling transforms to move teapot
 - But leave the cube alone for reference

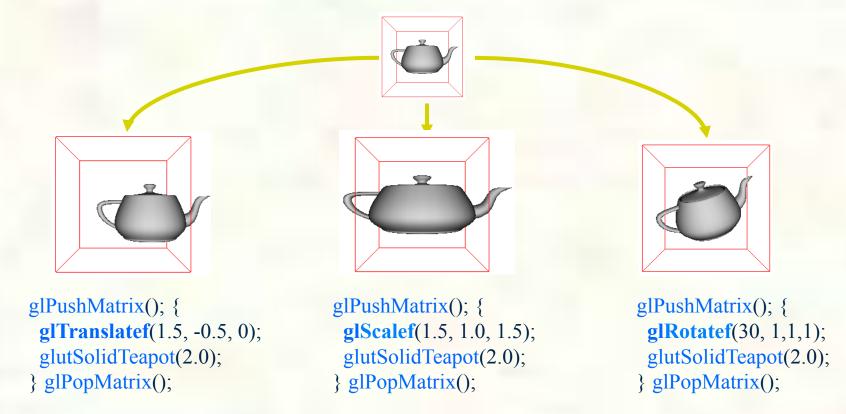

We "bracket" the modeling transform with glPushMatrix/glPopMatrix commands so the modeling transforms are "localized" to the particular object

Add Some Lighting

Some lighting makes the modeling more intuitive

We've not discussed lighting yet but per-vertex lighting allows a virtual light source to "interact" with the object's surface orientation and material properties

Modelview-Projection Matrix

- Let's consider the "combined" modelview matrix with the rotation
 - glRotate(30, 1,1,1) defines a rotation matrix
 - Rotating 30 degrees...
 - \blacksquare ...around an axis in the (1,1,1) direction

$$\begin{bmatrix} 0.9107 & -0.2440 & 0.3333 & 0 \\ 0.3333 & 0.9107 & -0.2440 & 0 \\ -0.2440 & 0.3333 & 0.9107 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$\begin{bmatrix} 1.25 & 0 & 0 & 0 \\ 0 & 1.667 & 0 & 0 \\ 0 & 0 & -1.1333 & -10.667 \\ 0 & 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0.9107 & -0.2440 & 0.3333 & 0 \\ 0.3333 & 0.9107 & -0.2440 & 0 \\ -0.2440 & 0.3333 & 0.9107 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

projection

view

model

Combining All Three

Matrix-by-matrix multiplication is associative so PVM = P(VM) = (PV)M

OpenGL keeps V and M "together" because eye-space is a convenient space for lighting

$$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0.9107 & -0.2440 & 0.3333 & 0 \\ 0.3333 & 0.9107 & -0.2440 & 0 \\ -0.2440 & 0.3333 & 0.9107 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

view

model

$$\begin{bmatrix} 1.25 & 0 & 0 & 0 \\ 0 & 1.667 & 0 & 0 \\ 0 & 0 & -1.1333 & -10.667 \\ 0 & 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} 0.9107 & -0.2440 & 0.3333 & 0 \\ 0.3333 & 0.9107 & -0.2440 & 0 \\ -0.2440 & 0.3333 & 0.9107 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

projection

modelview

modelview-projection

Object- to Clip-space

$$\begin{bmatrix} x_{world} \\ y_{world} \\ z_{world} \\ w_{world} \end{bmatrix} = \begin{bmatrix} 0.9107 & -0.2440 & 0.3333 & 0 \\ 0.3333 & 0.9107 & -0.2440 & 0 \\ -0.2440 & 0.3333 & 0.9107 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_{object} \\ y_{object} \\ z_{object} \\ w_{object} \end{bmatrix}$$

view

$$\begin{bmatrix} x_{eye} \\ y_{eye} \\ z_{eye} \\ w_{eye} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_{world} \\ y_{world} \\ z_{world} \\ w_{world} \end{bmatrix}$$

$$\begin{bmatrix} x_{clip} \\ y_{clip} \\ z_{clip} \\ w_{clip} \end{bmatrix} = \begin{bmatrix} 1.25 & 0 & 0 & 0 \\ 0 & 1.667 & 0 & 0 \\ 0 & 0 & -1.1333 & -10.667 \\ 0 & 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} x_{eye} \\ y_{eye} \\ z_{eye} \\ w_{eye} \end{bmatrix}$$

object-to-world-to-eye-to-clip

modelview

$$\begin{bmatrix} x_{eye} \\ y_{eye} \\ z_{eye} \\ w_{eye} \end{bmatrix} = \begin{bmatrix} 0.9107 & -0.2440 & 0.3333 & 0 \\ 0.3333 & 0.9107 & -0.2440 & 0 \\ -0.2440 & 0.3333 & 0.9107 & -14 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_{object} \\ y_{object} \\ z_{object} \\ w_{object} \end{bmatrix}$$

projection

$$\begin{bmatrix} x_{clip} \\ y_{clip} \\ z_{clip} \\ w_{clip} \end{bmatrix} = \begin{bmatrix} 1.25 & 0 & 0 & 0 \\ 0 & 1.667 & 0 & 0 \\ 0 & 0 & -1.1333 & -10.667 \\ 0 & 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} x_{eye} \\ y_{eye} \\ z_{eye} \\ w_{eye} \end{bmatrix}$$

object-to-eye-to-clip

modelview-projection

$$\begin{bmatrix} x_{clip} \\ y_{clip} \\ z_{clip} \\ w_{clip} \end{bmatrix} = \begin{bmatrix} 1.1384 & -0.3050 & 0.4167 & 0 \\ 0.5556 & 1.5178 & -0.4067 & 0 \\ 0.2766 & -0.3778 & -1.0321 & 5.2 \\ 0.2440 & -0.3333 & -0.9107 & 14 \end{bmatrix} \begin{bmatrix} x_{object} \\ y_{object} \\ z_{object} \\ w_{object} \end{bmatrix}$$

object-to-clip

Complex Scene Example

Each character, wall, ceiling, floor, and light have their own modeling transformation

University of Texas at Austin CS354 - Computer Graphics Don Fussell

Representing Objects

- Interested in object's boundary
- Various approaches
 - Procedural representations
 - Often fractal

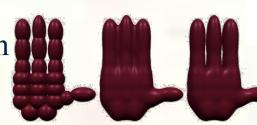

■ By far, the most popular method

Often displacement mapped

Implicit representation

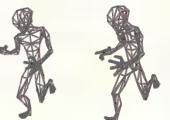

■ Blobby, volumetric

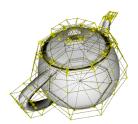

Quake 2 key frame triangle meshes

Utah Teapot

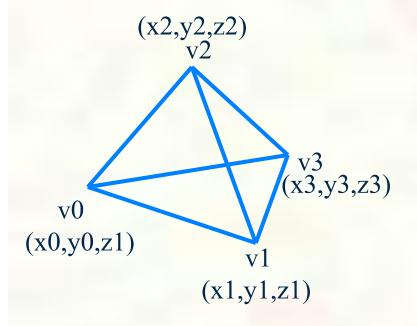

Focus on Triangle Meshes

- Easiest approach to representing object boundaries
- So what is a mesh and how should it be stored?
 - Simplest view
 - A set of triangles, each with its "own" 3 vertices
 - Essentially "triangle soup"
 - Yet triangles in meshes share edges by design
 - Sharing edges implies sharing vertices
 - More sophisticated view
 - Store single set of unique vertexes in array
 - Then each primitive (triangle) specifies 3 indices into array of vertexes
 - More compact
 - Vertex data size >> index size
 - Avoids redundant vertex data
 - Separates "topology" (how the mesh is connected) from its "geometry" (vertex positions and attributes)
 - Connectivity can be deduced more easily
 - Makes mesh processing algorithms easier
 - Geometry data can change without altering the topology

Consider a Tetrahedron

- Simplest closed volume
 - Consists of 4 triangles and 4 vertices
 - (and 4 edges)

triangle list

0: v0, v1, v2

1: v1,v3,v2

2: v3,v0,v2

3: v1,v0,v3

topology

vertex list

0: (x0,y0,z0)

1: (x1,y1,z1)

2: (x2,y2,z2)

3:(x3,y3,z3)

geometry
potentially on-GPU!

Benefits of Vertex Array Approach

- Unique vertices are stored once
 - Saves memory
 - On CPU, on disk, and on GPU
- Matches OpenGL vertex array model of operation
 - And this matches the efficient GPU mode of operation
 - The GPU can "cache" post-transformed vertex results by vertex index
 - Saves retransformation and redundant vertex fetching
 - Direct3D has the same model
 - Allows vertex data to be stored on-GPU for even faster vertex processing
 - OpenGL supported vertex buffer objects for this

- More about triangle mesh representation
- Scene graphs
