

Shading

Introduction

- Affine transformations help us to place objects into a scene.
- Before creating images of these objects, we'll look at models for how light interacts with their surfaces.
- Such a model is called a **shading model**.
- Other names:
 - Lighting model
 - Light reflection model
 - Local illumination model
 - Reflectance model
 - BRDF

An abundance of photons

- Properly determining the right color is *really hard*.
- Look around the room. Each light source has different characteristics. Trillions of photons are pouring out every second.
- These photons can:
 - interact with the atmosphere, or with things in the atmosphere
 - strike a surface and
 - be absorbed
 - be reflected (scattered)
 - cause fluorescence or phosphorescence.
 - interact in a wavelength-dependent manner
 - generally bounce around and around

Break problem into two parts

- Part 1:
 - What happens when photons interact with a particular point on a surface?
- “Local illumination model”
- Part 2:
 - How do photons bounce between surfaces?
 - And, what is the final result of all of this bouncing?
- “Global illumination model”
- Today we’re going to focus on Part 1.

Strategy for today

- We're going to build up to an *approximation* of reality called the **Phong illumination model**.
- It has the following characteristics:
 - *not* physically based
 - gives a first-order *approximation* to physical light reflection
 - very fast
 - widely used
- We will assume **local illumination**, i.e., light goes: light source \rightarrow surface \rightarrow viewer.
- No interreflections, no shadows.

Setup...

■ Given:

- a point **P** on a surface visible through pixel p
- The normal **N** at **P**
- The lighting direction, **L**, and intensity, I_ℓ , at **P**
- The viewing direction, **V**, at **P**
- The shading coefficients (material properties) at **P**

- Compute the color, I , of pixel p .
- Assume that the direction vectors are normalized:

$$\|\mathbf{N}\| = \|\mathbf{L}\| = \|\mathbf{V}\| = 1$$

Iteration zero

- The simplest thing you can do is...
- Assign each polygon a single color: $I = k_e$
where
 - I is the resulting intensity
 - k_e is the **emissivity** or intrinsic shade associated with the object
- This has some special-purpose uses, but not really good for drawing a scene.
- [Note: k_e is omitted in Watt.]

Iteration one

- Let's make the color at least dependent on the overall quantity of light available in the scene:

$$I = k_e + k_a I_a$$

- k_a is the **ambient reflection coefficient**.
 - really the reflectance of ambient light
 - “ambient” light is assumed to be equal in all directions
 - I_a is the **ambient intensity**.
-
- Physically, what is “ambient” light?

Wavelength dependence

- Really, k_e , k_a , and I_a are functions over all wavelengths λ .
- Ideally, we would do the calculation on these functions.
We would start with:

$$I(\lambda) = k_e(\lambda) + k_a(\lambda)I_a(\lambda)$$

- then we would find good RGB values to represent the spectrum $I(\lambda)$.
- Traditionally, though, k_e , k_a and I_a are represented as RGB triples, and the computation is performed on each color channel separately: $I_R = k_{e,R} + k_{a,R}I_{a,R}$

$$I_G = k_{e,G} + k_{a,G}I_{a,G}$$

$$I_B = k_{e,B} + k_{a,B}I_{a,B}$$

Diffuse reflectors

- Diffuse reflection occurs from dull, matte surfaces, like latex paint, or chalk.
- These **diffuse** or **Lambertian** reflectors reradiate light equally in all directions.
- Picture a rough surface with lots of tiny **microfacets**.

Diffuse reflectors

- ...or picture a surface with little pigment particles embedded beneath the surface (neglect reflection at the surface for the moment):

- The microfacets and pigments distribute light rays in all directions.
- Embedded pigments are responsible for the coloration of diffusely reflected light in plastics and paints.
- Note: the figures above are intuitive, but not strictly (physically) correct.

Diffuse reflectors, cont.

- The reflected intensity from a diffuse surface does not depend on the direction of the viewer. The incoming light, though, does depend on the direction of the light source:

Iteration two

- The incoming energy is proportional to $\cos(\theta)$, giving the diffuse reflection equations:

$$\begin{aligned} I &= k_e + k_a I_a + k_d I_\ell \cos(\theta)_+ \\ &= k_e + k_a I_a + k_d I_\ell (\mathbf{N} \cdot \mathbf{L})_+ \end{aligned}$$

where:

- k_d is the **diffuse reflection coefficient**
- I_ℓ is the intensity of the light source
- \mathbf{N} is the normal to the surface (unit vector)
- \mathbf{L} is the direction to the light source (unit vector)
- $(x)_+$ means $\max \{0, x\}$

[Note: Watt uses I_i instead of I_ℓ .]

Specular reflection

- **Specular reflection** accounts for the highlight that you see on some objects.
- It is particularly important for *smooth, shiny* surfaces, such as:
 - metal
 - polished stone
 - plastics
 - apples
 - skin
- **Properties:**
 - Specular reflection depends on the viewing direction V .
 - For non-metals, the color is determined solely by the color of the light.
 - For metals, the color may be altered (e.g., brass)

Specular reflection “derivation”

- For a perfect mirror reflector, light is reflected about \mathbf{N} , so

$$I = \begin{cases} I_\ell & \text{if } \mathbf{V} = \mathbf{R} \\ 0 & \text{otherwise} \end{cases}$$

- For a near-perfect reflector, you might expect the highlight to fall off quickly with increasing angle ϕ .
- Also known as:
 - “rough specular” reflection
 - “directional diffuse” reflection
 - “glossy” reflection

Derivation, cont.

- One way to get this effect is to take $(\mathbf{R} \cdot \mathbf{V})$, raised to a power n_s .
- As n_s gets larger,
 - the dropoff becomes {more,less} gradual
 - gives a {larger,smaller} highlight
 - simulates a {more,less} mirror-like surface

Iteration three

- The next update to the Phong shading model is then:

$$I = k_e + k_a I_a + k_d I_\ell (\mathbf{N} \cdot \mathbf{L})_+ + k_s I_\ell (\mathbf{R} \cdot \mathbf{V})_+^{n_s}$$

where:

- k_s is the **specular reflection coefficient**
- n_s is the **specular exponent** or **shininess**
- \mathbf{R} is the reflection of the light about the normal (unit vector)
- \mathbf{V} is viewing direction (unit vector)

[Note: Watt uses n instead of n_s .]

What is incoming light intensity?

So far we've just been considering what happens at the surface itself.

How does incoming light intensity change as light moves further away?

Intensity drop-off with distance

- OpenGL supports different kinds of lights: point, directional, and spot.
- For point light sources, the laws of physics state that the intensity of a point light source must drop off inversely with the square of the distance.
- We can incorporate this effect by multiplying I_ℓ by $1/d^2$.
- Sometimes, this distance-squared dropoff is considered too “harsh.” A common alternative is:

$$f_{atten}(d) = \frac{1}{a + bd + cd^2}$$

with user-supplied constants for a , b , and c .

[Note: not discussed in Watt.]

Iteration four

- Since light is additive, we can handle multiple lights by taking the sum over every light.
- Our equation is now:

$$I = k_e + k_a I_a + \sum_j f_{atten}(d_j) I_{\ell_j} \left[k_d (\mathbf{N} \cdot \mathbf{L}_j)_+ + k_s (\mathbf{R}_j \cdot \mathbf{V})_+^{n_s} \right]$$

- This is the Phong illumination model.

Choosing the parameters

- Experiment with different parameter settings. To get you started, here are a few suggestions:
 - Try n_s in the range $[0,100]$
 - Try $k_a + k_d + k_s < 1$
 - Use a small k_a (~ 0.1)

	n_s	k_d	k_s
Metal	large	Small, color of metal	Large, color of metal
Plastic	medium	Medium, color of plastic	Medium, white
Planet	0	varying	0

BRDF

- The Phong illumination model is really a function that maps light from incoming (light) directions to outgoing (viewing) directions:

$$f_r(\omega_{in}, \omega_{out})$$

- This function is called the **Bi-directional Reflectance Distribution Function (BRDF)**.
- Here's a plot with ω_{in} held constant:

- Physically valid BRDF's obey Helmholtz reciprocity:

$$f_r(\omega_{in}, \omega_{out}) = f_r(\omega_{out}, \omega_{in})$$

and should conserve energy (no light amplification).

$$f_r(\omega_{in}, \omega_{out}) = f_r(\mathbf{L}, \mathbf{V})$$

How do we express Phong model using explicit BRDF?

$$I = k_e + k_a I_a + \sum_j f_{atten}(d_j) I_{\ell_j} \left[k_d (\mathbf{N} \cdot \mathbf{L}_j)_+ + k_s (\mathbf{R}_j \cdot \mathbf{V})_+^{n_s} \right]$$

More sophisticated BRDF's

Cook and Torrance, 1982

Westin, Arvo, Torrance 1992

Summary

- Local vs. Global Illumination Models
- Local Illumination Models:
 - Phong – Physically inspired, but not truly physically correct.
 - Arbitrary BRDFs
- In applying the Phong model, we assumed unshadowed “point” light sources.
