## Building complex models

We can extend the idea of subdivision from curves to surfaces...

## Subdivision surfaces

■ Chaikin's use of subdivision for curves inspired similar techniques for subdivision surfaces.
$\square$ Iteratively refine a control polyhedron (or control mesh) to produce the limit surface

$$
\sigma=\lim _{j \rightarrow \infty} M^{j}
$$

using splitting and averaging steps.

## Triangular subdivision

■ There are a variety of ways to subdivide a poylgon mesh.

- A common choice for triangle meshes is $4: 1$ subdivision - each triangular face is split into four subfaces:

Original

After splitting

## Loop averaging step

- Once again we can use masks for the averaging step:

Vertex neighorhood

Averaging mask

- where

$$
\mathbf{Q} \leftarrow \frac{\alpha(n) \mathbf{Q}+\mathbf{Q}_{1}+\cdots+\mathbf{Q}_{n}}{\alpha(n)+n} \quad \alpha(n)=\frac{n(1-\beta(n))}{\beta(n)} \quad \beta(n)=\frac{5}{4}-\frac{(3+2 \cos (2 \pi / n))^{2}}{32}
$$

- These values, due to Charles Loop, are carefully chosen to ensure smoothness - namely, tangent plane or normal continuity.
- Note: tangent plane continuity is also known as $\mathrm{G}^{1}$ continuity for surfaces.

## Loop evaluation and tangent masks

- As with subdivision curves, we can split and average a number of times and then push the points to their limit positions.

Evaluation mask

Tangent masks

$$
\begin{aligned}
\mathbf{Q}^{\infty} & =\frac{\varepsilon(n) \mathbf{Q}+\mathbf{Q}_{1}+\cdots+\mathbf{Q}_{n}}{\varepsilon(n)+n} \\
\mathbf{T}_{1}^{\infty} & =\tau_{1}(n) \mathbf{Q}_{1}+\tau_{2}(n) \mathbf{Q}_{2}+\cdots+\tau_{n}(n) \mathbf{Q}_{n} \\
\mathbf{T}_{2}^{\infty} & =\tau_{n}(n) \mathbf{Q}_{1}+\tau_{1}(n) \mathbf{Q}_{2}+\cdots+\tau_{n-1}(n) \mathbf{Q}_{n}
\end{aligned}
$$

- where $\quad \varepsilon(n)=\frac{3 n}{\beta(n)} \quad \tau_{i}(n)=\cos (2 \pi i / n)$

■ How do we compute the normal?

## Recipe for subdivision surfaces

■ As with subdivision curves, we can now describe a recipe for creating and rendering subdivision surfaces:
$■$ Subdivide (split+average) the control polyhedron a few times. Use the averaging mask.
$■$ Compute two tangent vectors using the tangent masks.
■ Compute the normal from the tangent vectors.
$\square$ Push the resulting points to the limit positions. Use the evaluation mask.
■ Render!

## Adding creases without trim curves

- In some cases, we want a particular feature such as a crease to be preserved. With NURBS surfaces, this required the use of trim curves.
- For subdivision surfaces, we can just modify the subdivision mask:

- This gives rise to $\mathrm{G}^{0}$ continuous surfaces (i.e., having positional but not tangent plane continuity)

## Creases without trim curves, cont.

■ Here's an example using Catmull-Clark surfaces (based on subdividing quadrilateral meshes):

## Face schemes

- $4: 1$ subdivision of triangles is sometimes called a face scheme for subdivision, as each face begets more faces.
- An alternative face scheme starts with arbitrary polygon meshes and inserts vertices along edges and at face centroids:

- Catmull-Clark subdivision:

- Note: after the first subdivision, all polygons are quadilaterals in this scheme.

## Subdivision $=$ tensor-product patches $!$

- For a regular quadrilateral mesh, Catmull-Clark subdivision produces the same surface as tensorproduct cubic B-splines!
$\square$ But - it handles irregular meshes as well.
There are similar correspondences between other subdivision schemes and other tensor-product patch schemes.

These correspondences can be proven (but we won't do it...)

## Vertex schemes

- In a vertex scheme, each vertex begets more vertices. In particular, a vertex surrounded by $n$ faces is split into $n$ sub-vertices, one for each face:

After splitting

- Doo-Sabin subdivision:

- The number edges (faces) incident to a vertex is called its valence. Edges with only once incident face are on the boundary. After splitting in this subdivision scheme, all nonboundary vertices are of valence 4.

## Interpolating subdivision surfaces

- Interpolating schemes are defined by
- splitting
- averaging only new vertices
- The following averaging mask is used in butterfly subdivision:

- Setting $t=0$ gives the original polyhedron, and increasing small values of $t$ makes the surface smoother, until $t=1 / 8$ when the surface is provably $\mathrm{G}^{1}$.

There are several variants of Butterfly subdivision.

## Next class: Projections \& Z-Buffers

- Topics:
- How do projections from 3D world to

2D image plane work?

- How does the Z-buffer visibility algorithm (used in today's graphics hardware) work?
