

### Problem 7. (20 points):

We are running programs on a machine with the following characteristics:

- Values of type `int` are 32 bits. They are represented in two's complement, and they are right shifted arithmetically. Values of type `unsigned` are 32 bits.
- Values of type `float` are represented using the 32-bit IEEE floating point format, while values of type `double` use the 64-bit IEEE floating point format.

We generate arbitrary values `x`, `y`, and `z`, and convert them to other forms as follows:

```
/* Create some arbitrary values */
int x = random();
int y = random();
int z = random();
/* Convert to other forms */
unsigned ux = (unsigned) x;
unsigned uy = (unsigned) y;
double dx = (double) x;
double dy = (double) y;
double dz = (double) z;
```

For each of the following C expressions, you are to indicate whether or not the expression *always* yields 1. If so, circle “Y”. If not, circle “N”. You will be graded on each problem as follows:

- If you circle no value, you get 0 points.
- If you circle the right value, you get 2 points.
- If you circle the wrong value, you get −1 points (so don't just guess wildly).

Expression	Always True?
<code>(x &lt; y) == (-x &gt; -y)</code>	Y N
<code>((x + y) &lt;&lt; 4) + y - x == 17 * y + 15 * x</code>	Y N
<code>~x + ~y + 1 == ~(x + y)</code>	Y N
<code>ux - uy == -(y - x)</code>	Y N
<code>(x &gt;= 0)    (x &lt; ux)</code>	Y N
<code>((x &gt;&gt; 1) &lt;&lt; 1) &lt;= x</code>	Y N
<code>(double)(float) x == (double) x</code>	Y N
<code>dx + dy == (double) (y + x)</code>	Y N
<code>dx + dy + dz == dz + dy + dx</code>	Y N
<code>dx * dy * dz == dz * dy * dx</code>	Y N
