

Problem

Use the Rabin-Karp algorithm to search a string of digits for a given pattern. For a string of 4 digits, $abcd$, the hash function, val , to be used is $(a + b + c + d) \bmod 11$. Show the hash function values for all 4-digit substrings in the following string. Find all occurrences of “2 6 4 2”.

3 7 2 6 4 1 9 8 2 9

Solution

| | | | | | | | | | | |
|----------|---|---|---|---|---|---|---|---|---|---|
| $text$ | 3 | 7 | 2 | 6 | 4 | 1 | 9 | 8 | 2 | 9 |
| $val(s)$ | | 7 | 8 | 2 | 9 | 0 | 9 | 6 | | |

Table 1: Computing Function values in Rabin-Karp Algorithm

The string 2 6 4 2 hashes to the value 3. There is no substring which hashes to 3.
