Relating Two Dialects of Answer Set Programming

Amelia Harrison and Vladimir Lifschitz

Abstract
The input language of the answer set solver CLINGO is based on the definition of a stable model proposed by Paolo Ferraris. The semantics of the ASP-Core language, developed by the ASP Standardization Working Group, uses the approach to stable models due to Wolfgang Faber, Nicola Leone, and Gerald Pfeifer. The two languages are based on different versions of the stable model semantics, and the ASP-Core document requires, “for the sake of an uncontroversial semantics,” that programs avoid the use of recursion through aggregates. In this paper we prove that the absence of recursion through aggregates does indeed guarantee the equivalence between the two versions of the stable model semantics, and show how that requirement can be relaxed without violating the equivalence property.

Introduction
Early work on autoepistemic logic and default logic has led to the development of the stable model semantics of logic programs, which serves as the semantic basis of answer set programming (ASP). The ASP-Core document\footnote{https://www.mat.unical.it/aspcomp2013/ASPSstandardization.}, produced in 2012–2015 by the ASP Standardization Working Group, was intended as a specification for the behavior of answer set programming systems. The existence of such a specification enables system comparisons and competitions to evaluate such systems.

The semantics of ASP programs described in that document differs from that of the input language of the widely used answer set solver CLINGO.\footnote{http://potassco.org/clingo.} The two languages are based on different versions of the stable model semantics: the former on the FLP-semantics, proposed by Faber, Leone, and Pfeifer (2004) and generalized to arbitrary propositional formulas by Truszczynski (2012), and the latter on the approach of Ferraris (2005).

In view of this discrepancy, the ASP-Core document includes a warning: “For the sake of an uncontroversial semantics, we require [the use of] aggregates to be non-recursive” (Section 6.3 of Version 2.03c). Including this warning was apparently motivated by the belief that in the absence of recursion through aggregates the functionality of CLINGO conforms with the ASP-Core semantics.

In this paper, that belief is turned into a theorem: for a programming language that is essentially a large subset of ASP-Core\footnote{This language does not include classical negation, weak constraints, optimize statements, and queries, and it does not allow multiple aggregate elements within the same aggregate atom. On the other hand, it includes the symbols $\inf$ and $\sup$ from the CLINGO language.}, we prove that the absence of recursion through aggregates guarantees the equivalence between ASP-Core and CLINGO. Our theorem is actually stronger, in two ways. First, it shows that the view of recursion through aggregates adopted in the ASP-Core document is unnecessarily broad when applied to disjunctive programs (see Footnote 9). Second, it shows that aggregates that do not contain negation as failure can be used recursively without violating that property. For example, the rule

\[
\text{val}(W,0) :- \text{gate}(G,\text{and}), \text{output}(W,G), \text{card}(W: \text{val}(W,0), \text{input}(W,G)) > 0
\]

which describes the propagation of binary signals through an and-gate (Gelfond and Zhang, 2014, Example 9) has the same meaning in both languages.

A few years ago it was difficult not only to prove such a theorem, but even to state it properly, because a mathematically precise semantics of the language of CLINGO became available only with the publication by Gebser et al. (2015). The concept of a stable model for CLINGO programs is defined in that paper in two steps: first a transformation $\tau$ is introduced,\footnote{An oversight in the definition of $\tau$ in that publication is corrected in the arXiv version of the paper, http://arXiv.org/abs/1507.06576v2.} which turns a CLINGO program into a set of infinitary propositional formulas, and then the definition of a stable model due to Ferraris (2005), extended to the infinitary case by Truszczynski (2012), is invoked. Infinite conjunctions and disjunctions are needed when the program uses local variables. We will refer to stable models in the sense of this two-step definition as “FT-stable.”

The semantics of ASP-Core programs is precisely defined in Section 2 of the ASP-Core document, but that definition is not completely satisfactory: it is not applicable to programs
with local variables. The problem is that the definition of a ground instance in Section 2.2 of the document includes replacing the list \(e_1;\ldots;e_n\) of aggregate elements in an aggregate atom by its instantiation \(\text{inst}([e_1;\ldots;e_n])\); the instantiation, as defined in the document, is an infinite object, because the set of symbols that can be substituted for local variables includes arbitrary integers and arbitrarily long symbolic constants. So the result of the replacement is not an ASP-Core program. Prior to addressing the main topic of this note, we propose a way to correct this defect. We use a two-step procedure, similar to the one employed by Gebser et al. (2015): after applying a transformation \(\tau_1\), almost identical to \(\tau\), it refers to a straightforward generalization of the definition of a stable model due to Faber, Leone, and Pfeifer (2004) to the infinite case. In the absence of local variables, this semantics is consistent with the ASP-Core document (Harrison, 2017, Chapter 12). Stable models in the sense of this two-step definition will be called “FLP-stable.”

We start by defining the syntax of programs, two versions of the stable model semantics of infinitary formulas, and two versions of the semantics of programs. The main theorem asserts that if the aggregates used in a program recursively do not contain negation then the FLP-stable models of the program are the same as its FT-stable models. To prove the theorem we investigate under what conditions the models of a set of infinitary propositional formulas that are stable in the sense of Faber et al. are identical to the models stable in the sense of Ferraris and Truszczynski.

**Syntax of Programs**

The syntax of programs is described here in an abstract fashion, in the spirit of Gebser et al. (2015), so as to avoid inessential details related to the use of ASCII characters.

We assume that three pairwise disjoint sets of symbols are selected: numerals, symbolic constants, and variables. Further, we assume that these sets do not contain the symbols

\[
\begin{align*}
+ & \quad - \quad \times \quad / \tag{1} \\
\inf & \quad \sup \tag{2} \\
= & \quad \neq \quad < \quad > \quad \leq \quad \geq \tag{3} \\
not & \quad \land \quad \lor \quad \leftarrow \tag{4} \\
, \quad : \quad (\quad ) \quad \{\quad \} \tag{5}
\end{align*}
\]

and are different from the aggregate names count, sum, max, min. All these symbols together form the alphabet of programs, and rules will be defined as strings over this alphabet.

We assume that a 1–1 correspondence between the set of numerals and the set \(\mathbb{Z}\) of integers is chosen. For every integer \(n\), the corresponding numeral will be denoted by \(\pi^n\).

**Terms** are defined recursively, as follows:

- all numerals, symbolic constants, and variables, as well as symbols (2) are terms;
- if \(f\) is a symbolic constant and \(t\) is a non-empty tuple of terms (separated by commas) then \(f(t)\) is a term;
- if \(t_1\) and \(t_2\) are terms and \(*\) is one of the symbols (1) then \((t_1 * t_2)\) is a term.

A term, or a tuple of terms, is **ground** if it does not contain variables. A term, or a tuple of terms, is **precomputed** if it contains neither variables nor symbols (1). We assume a total order on precomputed terms such that \(\inf\) is its least element, \(\sup\) is its greatest element, and, for any integers \(m\) and \(n\), \(m \leq n\) iff \(m \leq n\).

For each aggregate name we define a function that maps every set of non-empty tuples of precomputed terms to a precomputed term. Functions corresponding to each of the aggregate names are defined below using the following terminology. If the first member of a tuple \(t\) of precomputed terms is a numeral \(\pi^n\) then we say that the integer \(n\) is the **weight** of \(t\); if \(t\) is empty or its first member is not an numeral then the weight of \(t\) is 0. For any set \(T\) of tuples of precomputed terms,

- \(\text{count}(T)\) is the numeral corresponding to the cardinality of \(T\) if \(T\) is finite, and \(\sup\) otherwise;
- \(\text{sum}(T)\) is the numeral corresponding to the sum of the weights of all tuples in \(T\) if \(T\) contains finitely many tuples with non-zero weights, and 0 otherwise;
- \(\text{min}(T)\) is \(\sup\) if \(T\) is empty, the least element of the set consisting of the first elements of the tuples in \(T\) if \(T\) is a finite non-empty set, and \(\inf\) if \(T\) is infinite;
- \(\text{max}(T)\) is \(\inf\) if \(T\) is empty, the greatest element of the set consisting of the first elements of the tuples in \(T\) if \(T\) is a finite non-empty set, and \(\sup\) if \(T\) is infinite.

An **atom** is a string of the form \(p(t)\) where \(p\) is a symbolic constant and \(t\) is a tuple of terms. For any atom \(A\), the strings

\[
A \quad \text{not} \quad A \tag{6}
\]

are **symbolic literals**. An **arithmetic literal** is a string of the form \(t_1 \prec t_2\) where \(t_1, t_2\) are terms and \(\prec\) is one of the symbols (3). A **literal** is a symbolic or arithmetic literal.\(^6\)

An aggregate atom \(A\) is a string of the form

\[
\alpha \{t : L\} \prec s, \tag{7}
\]

where

- \(\alpha\) is an aggregate name,
- \(t\) is a tuple of terms,
- \(L\) is a tuple of literals called the “conditions” (if \(L\) is empty then the preceding colon may be dropped),
- \(\prec\) is one of the symbols (3),
- and \(s\) is a term.

For any aggregate atom \(A\), the strings (6) are aggregate literals; the former is called positive, and the latter is called negative.

A **rule** is a string of the form

\[
H_1 \lor \cdots \lor H_k \leftarrow B_1 \land \cdots \land B_n \tag{8}
\]

\(^6\)In the parlance of the ASP-Core document, atoms are “classical atoms,” arithmetic literals are “built-in atoms,” and literals are “naf-literals.”
(k, n ≥ 0), where each H_j is an atom, and each B_j is a literal or aggregate literal. The expression B_1 ∧ ⋅ ⋅ ⋅ ∧ B_n is the body of the rule, and H_1 ∨ ⋅ ⋅ ⋅ ∨ H_k is the head. A program is a finite set of rules.

About a variable we say that it is global
- in a symbolic or arithmetic literal L, if it occurs in L;
- in an aggregate atom (7) or its negation, if it occurs in s;
- in a rule (8), if it is global in at least one of the expressions H_i, B_j,
A variable that is not global is called local. A literal or a rule is closed if it has no global variables.

**Stable Models of Infinitary Formulas**

**Formulas**
Let σ be a propositional signature, that is, a set of propositional atoms. The sets F_0, F_1, . . . are defined as follows:
- F_0 = σ,
- F_{i+1} is obtained from F_i by adding expressions H^∧ and H^∨ for all subsets H of F_i, and expressions F → G for all F, G ∈ F_i.

The elements of ∪_{i=0}^∞ F_i are called (infinitary propositional) formulas over σ.

An infinitary formula, F ∧ G and F ∨ G are abbreviations for {F, G} ∧ and {F, G} ∨ respectively; ⊤ and ⊥ are abbreviations for ∅^∧ and ∅^∨; ¬F stands for F → ⊥, and F ⊔ G stands for (F → G) ∧ (G → F). Literals over σ are atoms from σ and their negations. If {F_i : i ∈ I} is a family of formulas from one of the sets F_i then the expression \bigwedge_i F_i stands for the formula \{F_i : i ∈ I\} ∧, and \bigvee_i F_i stands for \{F_i : i ∈ I\} ∨.

Subsets of a propositional signature σ will be called its interpretations. The satisfaction relation between an interpretation and a formula is defined recursively as follows:
- For every atom p from σ, I |= p if p ∈ I.
- I |= H^∧ if for every formula F in H, I |= F.
- I |= H^∨ if there is a formula F in H such that I |= F.
- I |= F → G if I \models F or I \models G.

We say that an interpretation satisfies a set H of formulas, or is a model of H, if it satisfies every formula in H. We say that H entails a formula F if every model of H satisfies F. Two sets of formulas are equivalent if they have the same models.

**FLP-Stable Models**
Let H be a set of infinitary formulas of the form G → H, where H is a disjunction of atoms from σ. The FLP-reduct FLP(H, I) of H w.r.t. an interpretation I of σ is the set of all formulas G → H from σ such that I satisfies G. We say that I is an FLP-stable model of H if it is minimal w.r.t. set inclusion among the models of FLP(H, I).

It is clear that I satisfies FLP(H, I) iff I satisfies H. Consequently every FLP-stable model of H is a model of H.

**FT-Stable Models**
The FT-reduct FT(F, I) of an infinitary formula F w.r.t. an interpretation I is defined as follows:
- For any atom p from σ, FT(p, I) = ⊥ if I \models p; otherwise FT(p, I) = p.
- FT(H^∧, I) = {FT(G, I) | G ∈ H^∧}.
- FT(H^∨, I) = {FT(G, I) | G ∈ H^∨}.
- FT(G → H, I) = ⊥ if I \models G → H; otherwise FT(G → H, I) = FT(G, I) → FT(H, I).

The FT-reduct FT(H, I) of a set H of formulas is defined as the set of the reducts FT(F, I) of all formulas F from H. An interpretation I is an FT-stable model of H if it is minimal w.r.t. set inclusion among the models of FT(H, I).

It is easy to show by induction that I satisfies FT(F, I) iff I satisfies F. Consequently every FT-stable model of a set of formulas is a model of that set.

It is easy to check also that if I does not satisfy F then FT(F, I) is equivalent to ⊥.

**Comparison**
An FLP-stable model of a set of formulas is not necessarily FT-stable, and an FT-stable model is not necessarily FLP-stable. For example, consider (the singleton set containing) the formula
\[ p ∨ ¬p → p. \]  
(9)
It has no FT-stable models, but the interpretation \{p\} is its FLP-stable model. On the other hand, the formula
\[ ¬¬p → p \]  
(10)
has two FT-stable models, ∅ and \{p\}, but latter is not FLP-stable.

It is clear that replacing the antecedent of an implication by an equivalent formula within any set of formulas does not affect its FLP-stable models. For instance, from the perspective of the FLP semantics, formula (9) has the same meaning as ⊤ → p, and (10) has the same meaning as p → p. On the other hand, the FLP-stable models may change if we break an implication of the form F ∨ G → H into F → H and G → H. For instance, breaking (9) into p → p and ¬p → p gives a set without FLP-stable models.

With the FT semantics, it is the other way around: it does matter, generally, whether we write ¬¬p or p in the antecedent of an implication, but breaking F ∨ G → H into two implications cannot affect the set of stable models.

Transformations of infinitary formulas that do not affect their FT-stable models were studied by Harrison et al. (2017). These authors extended, in particular, the logic of here-and-there introduced by Heyting (1930) to infinitary propositional formulas and showed that any two sets of infinitary formulas that have the same models in the infinitary logic of here-and-there have also the same FT-stable models.

**Semantics of Programs**
In this section, we define two very similar translations, τ_1 and τ. Each of them transforms any program into a set of infinitary formulas over the signature σ_0 consisting of all
Atoms of the form \( p(t) \), where \( p \) is a symbolic constant and \( t \) is a tuple of precomputed terms. The definition of \( \tau \) follows Gebser et al. (2015), and examples of using \( \tau \) can be found in that paper.

Given these translations, the two versions of the semantics of programs are defined as follows. The FLP-stable models of a program \( \Pi \) are the FLP-stable models of \( \tau \Pi \). The FT-stable models of \( \Pi \) are the FT-stable models of \( \tau \Pi \).

Semantics of Terms

The semantics of terms tells us, for every ground term \( t \), whether it is well-formed, and if it is, which precomputed term is considered its value.\(^7\)

- If \( t \) is a numeral, symbolic constant, or one of the symbols \( \text{inf} \) or \( \text{sup} \) then \( t \) is well-formed, and its value \( \text{val}(t) \) is \( t \) itself.
- If \( t \) is \( f(t_1, \ldots, t_n) \) and the terms \( t_1, \ldots, t_n \) are well-formed, then \( t \) is well-formed also, and \( \text{val}(t) \) is \( f(\text{val}(t_1), \ldots, \text{val}(t_n)) \).
- If \( t \) is \( (t_1 + t_2) \) and the values of \( t_1 \) and \( t_2 \) are numerals \( n_1, n_2 \) then \( t \) is well-formed, and \( \text{val}(t) \) is \( n_1 + n_2 \); similarly when \( t \) is \( (t_1 \times t_2) \).
- If \( t \) is \( (t_1/t_2) \), the values of \( t_1 \) and \( t_2 \) are numerals \( n_1, n_2 \), and \( n_2 \neq 0 \) then \( t \) is well-formed, and \( \text{val}(t) \) is \( [n_1/n_2] \).
- If \( t \) is a tuple \( t_1, \ldots, t_n \) of well-formed ground terms then we say that \( t \) is well-formed, and its value \( \text{val}(t) \) is the tuple \( \text{val}(t_1), \ldots, \text{val}(t_n) \).

A closed arithmetic literal \( t_1 \prec t_2 \) is well-formed if \( t_1 \) and \( t_2 \) are well-formed. A closed symbolic literal \( p(t) \) or \( \neg p(t) \) is well-formed if \( t \) is well-formed. A closed aggregate literal \( E \) or \( \neg E \), where \( E \) is (7), is well-formed if \( s \) is well-formed.

Semantics of Arithmetic and Symbolic Literals

A well-formed arithmetic literal \( t_1 \prec t_2 \) is true if \( \text{val}(t_1) \prec \text{val}(t_2) \), and false otherwise.

The result of applying the transformation \( \tau_1 \) to a well-formed symbolic literal is defined as follows:

\[
\tau_1(p(t)) = p(\text{val}(t)); \quad \tau_1(\neg p(t)) = \neg p(\text{val}(t)).
\]

About a tuple of well-formed literals we say that it is non-trivial if all arithmetic literals in it are true. If \( L \) is a non-trivial tuple of well-formed arithmetic and symbolic literals then \( \tau L \) stands for the conjunction of the formulas \( \tau_1L \) for all symbolic literals \( L \) in \( L \).

Semantics of Aggregate Literals

Let \( E \) be a well-formed aggregate atom (7), and let \( x \) be the list of variables occurring in \( t : L \). By \( A \) we denote the set of all tuples \( r \) of precomputed terms of the same length as \( x \) such that

(1) \( t^r_x \) is well-formed, and

(ii) \( L^x_r \) is well-formed and nontrivial.\(^8\)

For any subset \( \Delta \) of \( A \), by \( \text{val}(\Delta) \) we denote the set of tuples \( t^r_x \) for all \( r \in \Delta \). We say that \( \Delta \) justifies \( E \) if the relation \( \prec \) holds between \( \hat{\sigma}(\text{val}(\Delta)) \) and \( \text{val}(s) \). We define \( \tau_1E \) to be the disjunction of formulas

\[
\bigwedge_{r \in \Delta} \tau_1(L^x_r) \land \bigwedge_{r \in A \setminus \Delta} \neg \tau_1(L^x_r)
\]

over the subsets \( \Delta \) of \( A \) that justify \( E \).

Assume, for example, that \( E \) is

\[
\text{count}\{X:p(X)\} = 0.
\]

Then

- \( t \) is \( X, L \) is \( p(X), x \) is \( X \), and \( A \) is the set of all precomputed terms, \( \text{val}(\Delta) \) is \( \Delta \);
- \( \hat{\sigma}(\text{val}(\Delta)) \) is the cardinality of \( \Delta \) if \( \Delta \) is finite and \( \text{sup} \) otherwise;
- \( \Delta \) justifies (12) iff \( \Delta = \emptyset \);
- \( \tau_1E \) is the conjunction of the formulas \( \neg p(r) \) over all precomputed terms \( r \).

The result of applying \( \tau_1 \) to a negative aggregate literal \( \neg E \) is \( \neg \tau_1E \).

The definition of \( \tau_1L \) given earlier can be extended now to nontrivial tuples that may include well-formed literals of all three kinds: for any such tuple \( L \), \( \tau_1L \) stands for the conjunction of the formulas \( \tau_1L \) for all symbolic literals and aggregate literals \( L \) in \( L \).

Applying \( \tau_1 \) to Rules and Programs

(A1) The result of applying \( \tau_1 \) to a rule (8) is defined as the set of all formulas of the form

\[
\tau_1((B_1, \ldots, B_n)_r^x) \rightarrow \tau_1(H_1)_r^x \lor \cdots \lor \tau_1(H_k)_r^x
\]

where \( x \) is the list of all global variables of the rule, and \( r \) is any tuple of precomputed terms of the same length as \( x \) such that all literals \( (H_i)_r^x (B_j)_r^x \) are well-formed.

For any program \( \Pi \), \( \tau_1 \Pi \) stands for the union of the sets \( \tau_1R \) for all rules \( R \) of \( \Pi \).

Transformation \( \tau \)

The definition of \( \tau \) differs from the definition of \( \tau_1 \) in only one place: in the treatment of aggregate atoms. In the spirit of Ferraris (2005), we define \( \tau E \) to be the conjunction of the implications

\[
\bigwedge_{r \in \Delta} \tau(L^x_r) \rightarrow \bigvee_{r \in A \setminus \Delta} \tau(L^x_r)
\]

over the subsets \( \Delta \) of \( A \) that do not justify \( E \).

For example, if \( E \) is (12) then \( \tau E \) is

\[
\bigwedge_{\Delta \subseteq A, \Delta \neq \emptyset} \left( \bigwedge_{r \in \Delta} p(r) \rightarrow \bigvee_{r \in A \setminus \Delta} p(r) \right).
\]

\(^7\)In the input language of CLINGO, a term may contain “intervals”, such as 1..3, and in that more general setting a ground term may have several values.

\(^8\)Here \( t^x_r \) stands for the result of substituting \( r \) for \( x \) in \( t \). The meaning of \( L^x_r \) is similar.
It is easy to show that $\tau E$ is equivalent to $\tau_1 E$. Consider the disjunction $D$ of formulas (11) over all subsets $\Delta$ of $A$ that do not justify $E$. It is to see that every interpretation satisfies either $\tau_1 E$ or $D$. On the other hand, no interpretation satisfies both $D$ and $\tau_1 E$, because in every disjunctive term of $\tau_1 E$ and every disjunctive term of $D$ there is a pair of conflicting conjunctive terms. It follows that $D$ is equivalent to $-\tau_1 E$. It is clear that $D$ is also equivalent to $-\tau E$.

Since all occurrences of translations $\tau_1 E$ in implication (13) belong to its antecedent, it follows that $\tau$ could be used instead of $\tau_1$ in the definition of an FLP-stable model of a program. For the definition of an FT-stable model of a program, however, the difference between $\tau_1$ and $\tau$ is essential. Although the translation $\tau_1$ will not be used in the statement or proof of the main theorem, we introduce it here because it is simpler than $\tau$ in the sense that it in application to aggregate literals it does not produce implications. We anticipate that for establishing other properties of FLP-stable models it may be a useful tool.

**Main Theorem**

To see that the FLP and FT semantics of programs are generally not equivalent, consider the one-rule program

$$ p \leftarrow \text{count} \{ \top : \text{not } p \} < \top. \tag{15} $$

The result of applying $\tau$ to this program is $\neg\neg p \rightarrow p$. The FT-stable models are $\emptyset$ and $\{p\}$; the first of them is an FLP-stable model, and the second is not.

Our main theorem gives a condition ensuring that the FLP-stable models and FT-stable models of a program are the same. To state it, we need to describe the precise meaning of “recursion through aggregates.”

The *predicate symbol* of an atom $p(t_1, \ldots, t_n)$ is the pair $p/n$. The *predicate dependency graph* of a program $\Pi$ is the directed graph that

- has the predicate symbols of atoms occurring in $\Pi$ as its vertices, and
- has an edge from $p/n$ to $q/m$ if there is a rule $R$ in $\Pi$ such that $p/n$ is the predicate symbol of an atom occurring in the head of $R$, and $q/m$ is the predicate symbol of an atom occurring in the body of $R$.

We say that an occurrence of an aggregate literal $L$ in a rule $R$ is recursive with respect to a program $\Pi$ containing $R$ if for some predicate symbol $p/n$ occurring in $L$ and some predicate symbol $q/m$ occurring in the head of $R$ there exists a path from $p/n$ to $q/m$ in the predicate dependency graph of $\Pi$.

For example, the predicate dependency graph of program (15) has a single vertex $p/0$ and an edge from $p/0$ to itself. The aggregate literal in the body of this program is recursive. Consider, on the other hand, the one-rule program

$$ q \leftarrow \text{not count} \{ \top : p \} < \top. $$

Its predicate dependency graph has the vertices $p/0$ and $q/0$, and an edge from $q/0$ to $p/0$. Since there is no path from $p/0$ to $q/0$ in this graph, the aggregate literal in the body of this rule is not recursive.

We say that an aggregate literal is positive if it is an aggregate atom and all symbolic literals occurring in it are positive.

**Main Theorem** If every aggregate literal that is recursive with respect to a program $\Pi$ is positive then the FLP-stable models of $\Pi$ are the same as the FT-stable models of $\Pi$.

In particular, if all aggregate literals in $\Pi$ are positive then $\Pi$ has the same FLP- and FT-stable models. For example, consider the one-rule program

$$ p \leftarrow \text{count} \{ \top : p \} > 0. $$

The only aggregate literal in this program is positive; according to the main theorem, the program has the same FLP- and FT-stable models. Indeed, it is easy to verify that $\emptyset$ is the only FLP-stable model of this program and also its only FT-stable model.

**Main Lemma**

In this section we talk about infinitary formulas over an arbitrary propositional signature $\sigma$.

Formulas $p, \neg p, \neg\neg p$, where $p$ is an atom from $\sigma$, will be called extended literals. A *simple disjunction* is a disjunction of extended literals. A *simple implication* is an implication $A^\uparrow \rightarrow L^\uparrow$ such that its antecedent $A^\uparrow$ is a conjunction of atoms and its consequent $L^\uparrow$ is a simple disjunction. A conjunction of simple implications will be called a *simple formula*. Formulas of the form $G \rightarrow H$, where $G$ is a simple formula and $H$ is a disjunction of atoms, will be called *simple rules.*

For example, (9), (10) can be rewritten as simple rules

$$ (\top \rightarrow p \lor \neg p) \rightarrow p, \tag{16} $$

$$ (\top \rightarrow \neg \neg p) \rightarrow p. \tag{17} $$

In the proof of Main Theorem we will show how any formula obtained by applying transformation $\tau$ to a program can be transformed into a simple rule with the same meaning.

A *simple program* is a set of simple rules.

In the statement of Main Lemma below, we refer to simple programs that are “FT-tight” and “FLP-tight.” The lemma asserts that if a program is FT-tight then its FLP-stable models are FT-stable; if a program is FLP-tight then its FT-stable models are FLP-stable. To describe these two classes of simple programs we need the following preliminary definitions.

An atom $p$ occurs strictly positively in a simple formula $F$ if there is a conjunctive term $A^\uparrow \rightarrow L^\uparrow$ in $F$ such that $p$ belongs to $L$. An atom $p$ occurs positively in a simple formula $F$ if there is a conjunctive term $A^\uparrow \rightarrow L^\uparrow$ in $F$ such that $p$ or $\neg\neg p$ belongs to $L$.

We define the (extended positive) dependency graph of a simple program $\mathcal{H}$ to be the graph that has

---

9The definition of the predicate dependency graph in the ASP-Core document includes also edges between predicate symbols of atoms occurring in the head of the same rule. Dropping these edges from the graph makes the assertion of the main theorem stronger.

10Note that a simple rule is not a rule in the sense of the programming language described above; it is an infinitary propositional formula of a special syntactic form.
• all atoms occurring in $H$ as its vertices, and
• an edge from $p$ to $q$ if for some formula $G \rightarrow H$ in $H$, $p$ is a disjunctive term in $H$ and $q$ occurs positively in $G$.

For example, the simple programs (16), (17) have the same dependency graph: a self-loop at $p$.

A simple implication $A^\land \rightarrow L^\lor$ will be called positive if $L$ is a set of atoms, and non-positive otherwise. An edge from $p$ to $q$ in the dependency graph of a simple program $H$ will be called FT-critical if for some formula $G \rightarrow H$ in $H$, $p$ is a disjunctive term in $H$ and $q$ occurs strictly positively in some non-positive conjunctive term $D$ of $G$. We call a simple program FT-tight if its dependency graph has no path containing infinitely many FT-critical edges.

Consider, for example, the dependency graph of program (16). Its only edge—the self-loop at $p$—is FT-critical, because the implication $\top \rightarrow p \lor \neg p$ is non-positive, and $p$ occurs strictly positively in it. It follows that the program is not FT-tight: consider the path consisting of infinitely many repetitions of this self-loop. On the other hand, in the dependency graph of program (17) the same edge is not FT-critical, because $p$ does not occur strictly positively in the implication $\top \rightarrow \neg p$. Program (17) is FT-tight.

An edge from $p$ to $q$ in the dependency graph of a simple program $H$ will be called FLP-critical if for some simple rule $G \rightarrow H$ in $H$, $p$ is a conjunctive term in $H$ and, for some conjunctive term $A^\land \rightarrow L^\lor$ of $G$, $\neg q$ belongs to $L$. We call a simple program FLP-tight if its dependency graph has no path containing infinitely many FLP-critical edges.

It is clear that if there are no extended literals of the form $\neg q$ in a simple program then there are no FLP-critical edges in its dependency graph, so that the program is FLP-tight. For example, (16) is a simple program of this kind. On the other hand, in the dependency graph of program (17) the self-loop at $p$ is FLP-critical, so that the program is not FLP-tight.

Main Lemma For any simple program $H$,

(a) if $H$ is FT-tight then all FLP-stable models of $H$ are FT-stable;
(b) if $H$ is FLP-tight then all FT-stable models of $H$ are FLP-stable.

Some parts of the proof of the lemma below are inspired by results from Ferraris, Lee, and Lifschitz (2006).

Proof of Main Lemma

If $F$ is a simple disjunction and $X$ is a set of atoms, by $F^\land_X$ we denote the simple disjunction obtained from $F$ by removing all disjunctive terms that belong to $X$. If $F$ is a simple implication $A^\land \rightarrow L^\lor$ then by $F^\land_X$ we denote $F$ itself if

$A \cap X$ is non-empty, and $A^\land \rightarrow (L^\lor)^K_X$ otherwise. If $F$ is a simple formula then $F^\land_X$ stands for the simple formula obtained by applying this transformation to all conjunctive terms of $F$. It is clear that $F^\land_X$ entails $F$.

For any simple program $H$, by $H^K_X$ we denote the simple program obtained from $H$ by applying this transformation to $G$ and $H$ for each simple rule $G \rightarrow H$ in $H$.

**Lemma 1** Let $I$ be a model of a simple program $H$, $X$ be a set of atoms, and $K$ be a subset of $X$ such that the dependency graph of $H$ has no edges from atoms in $K$ to atoms in $X \setminus K$. If $I$ satisfies $H^K_X$, then $I$ satisfies $H^K_{X \cup K}$.

**Proof.** Assume on the contrary that $I$ does not satisfy $H^K_{X \cup K}$. Then there is a simple rule $G \rightarrow H$ in $H$ such that $I$ satisfies $G^K_K$ but does not satisfy $H^K_{X \cup K}$. Further, since $I$ satisfies $G^K_K$ and $G^K_K$ entails $G$, $I$ satisfies $G$ as well. Then since $I$ is a model of $H$, $I$ satisfies $H$. Since $I$ satisfies $H$ but does not satisfy $H^K_{X \cup K}$, there is some atom $p$ in $H$ that is also in $K$. Now, since $I$ satisfies $G^K_K$ it must also satisfy $G^K_X$. Indeed, if this were not the case, there would be some atom $q$ occurring positively in $G$ and also occurring in $X \setminus K$. Then there would be an edge from $p \in K$ to $q \in X \setminus K$, contradicting the assumption of the lemma. On the other hand, $I$ does not satisfy $H^K_X$, since $I$ does not satisfy $H^K_K$ and $K$ is a subset of $X$. We may conclude that $I$ does not satisfy $G^K_X \rightarrow H^K_{X \cup K}$ and therefore does not satisfy $H^K_{X \cup K}$.

**Lemma 2** Let $I$ be a model of a simple program $H$ and let $K$ be a subset of $I$ such that there are no FT-critical edges in the subgraph of the dependency graph of $H$ induced by $K$. If $I \models H^K_K$ then $I \setminus K$ satisfies the FLP-reduct of $H$ with respect to $I$.

**Proof.** Consider a simple rule $G \rightarrow H$ in $H$ such that $I \models G$, so that $G \rightarrow H$ is in the FLP-reduct of $H$. We will show that $I \setminus K$ satisfies $G \rightarrow H$. Since $I \models H^K_K$, either $I \not\models G^K_K$ or $I \models H^K_K$.

**Case 1:** $I \models H^K_K$. Then $H$ has a disjunctive term that belongs to $I$ but not to $K$, so that $I \setminus K \models H$. We conclude that $I \setminus K \models G \rightarrow H$.

**Case 2:** $I \not\models G^K_K$. Consider a conjunctive term $A^\land \rightarrow L^\lor$ in $G$ such that $I \not\models A^\land \rightarrow (L^\lor)^K_K$. Since $I \models G$, $I \models A^\land \rightarrow L^\lor$. It follows that $A \cap K$ is empty and that $I$ satisfies both $A^\land$ and $L^\lor$ but does not satisfy $(L^\lor)^K_K$.

**Case 2.1:** $A^\land \rightarrow L^\lor$ is positive. Then $L$ is a set of atoms. Since $I \not\models (L^\lor)^K_K$ all atoms from $L$ that are also in $K$. So $I \setminus K \not\models L^\lor$. Since $A \cap K$ is empty and $I$ satisfies $A^\land$, $I \setminus K$ also satisfies $A^\land$. We may conclude that $I \setminus K \not\models G$ so that $I \setminus K \models G \rightarrow H$.

**Case 2.2:** $A^\land \rightarrow L^\lor$ is non-positive. Since $I$ satisfies $L^\lor$ but not $(L^\lor)^K_K$, there is an atomic disjunctive term $p \in L$ that belongs to $I \cap K$. Then $p$ occurs positively in $G$. It follows that no disjunctive term in $H$ occurs in $K$. (If there were
such a disjunctive term \( q \) in \( H \) then, since \( A^\uparrow \to L^\uparrow \) is non-positive, there would be an FT-critical edge from \( q \) to \( p \) in the subgraph of the dependency graph of \( H \) induced by \( K \). But the condition of the lemma stipulates that there are no FT-critical edges in that graph.) Since \( I \) satisfies \( G \) and is a model of the program, \( I \) satisfies \( H \) as well. Since no atoms from \( K \) occur in \( H \), it follows that \( I \setminus K \) satisfies \( H \), so that \( I \setminus K \) satisfies \( G \to H \).

**Lemma 3** If \( H \) is an FT-tight simple program and \( X \) is a non-empty set of atoms, then there exists a non-empty subset \( K \) of \( X \) such that in the subgraph of the dependency graph of \( H \) induced by \( X \)

(i) there are no edges from \( K \) to atoms in \( X \setminus K \), and

(ii) no atom in \( K \) has outgoing FT-critical edges.

**Proof.** Consider the subgraph of the dependency graph of \( H \) induced by \( X \). It contains some vertex \( b \) such that there is no path starting at \( b \) that contains an FT-critical edge. (If there were no such vertex \( b \), then there would be a path containing infinitely many FT-critical edges and \( H \) would not be FT-tight.) Take \( K \) to be the set of all vertices reachable from \( b \). It is clear that condition (i) is satisfied. Furthermore, since all atoms in \( K \) are reachable from \( b \), and no path starting at \( b \) contains an FT-critical edge, none of the atoms in \( K \) have outgoing FT-critical edges in the subgraph of the dependency graph of \( H \) induced by \( X \). So condition (ii) is satisfied as well.

**Lemma 4** If \( H \) is an FT-tight simple program and \( I \) is an FLP-stable model of \( H \), then for every non-empty subset \( X \) of \( I \), \( I \not\models H_X \).

**Proof.** Assume on the contrary that there is some non-empty subset \( X \) of \( I \) such that \( I \models H_X \). By Lemma 3, there is a non-empty subset \( K \) of \( X \) meeting conditions (i) and (ii). Since \( I \models H_X \) and \( K \) satisfies (i), by Lemma 1 we may conclude that \( I \models H_K \). Since \( K \) satisfies condition (ii) and is a subset of \( X \), it is clear that there are no FT-critical edges in the subgraph of the dependency graph of \( H \) induced by \( K \). So by Lemma 2, \( I \setminus K \) satisfies the FLP-reduct of \( H \), contradicting the assumption that \( I \) is FLP-stable.

**Lemma 5** Let \( G \) be a simple disjunction or a simple formula, and let \( X \) be a set of atoms. An interpretation \( I \) satisfies \( G_X \) iff it satisfies \( FT(G, I)_\perp^X \).

**Proof.** To prove the assertion for a simple disjunction, it is sufficient to consider the case when \( G \) is a single extended literal. If \( G \) is an atom \( p \),

\[ I \models p_X^\perp \iff p \in I \text{ and } p \not\in X \iff I \models FT(p, I)_\perp^X. \]

If \( G \) is either \( \neg p \) or \( \neg \neg p \), then \( G_X^\perp \) is \( G \) and \( FT(G, I)_\perp^X \) is \( FT(G, I) \). It is clear that \( I \) satisfies \( G \) iff it satisfies \( FT(G, I) \).

To prove the assertion of the lemma for simple formulas, it is sufficient to consider the case when \( G \) is a single simple implication \( A^\uparrow \to L^\uparrow \). If \( I \) does not satisfy \( G \) then it does not satisfy \( G_X^\perp \) either; on the other hand, in this case \( FT(G, I) \) is \( \perp \), and so is \( FT(G, I)_\perp^X \). Otherwise, \( FT(G, I)_\perp^X \) is

\[ (FT(A^\uparrow, I) \to FT(L^\uparrow, I))_\perp^X. \]  

We consider two cases corresponding to whether or not \( A \cap X \cap I \) is empty. If \( A \cap X \cap I \) is empty, \( I \) does not satisfy

\[ (A \subseteq I \text{ and } I \not\models FT(L^\uparrow, I)_\perp^X, \]

or equivalently,

\[ I \models A^\uparrow \text{ and } I \not\models (L^\uparrow)_\perp^X. \]

If on the other hand, \( A \cap X \cap I \) is non-empty, then (18) is \( FT(G, I) \) and \( G_X^\perp \) is \( G \).

**Lemma 6** For any simple disjunction \( G \) and any interpretations \( I \) and \( J \), \( J \models FT(G, I) \iff I \models FT(G, I)_\perp^J \).

**Proof.** It is sufficient to prove the lemma for the case when \( G \) is a single extended literal. If \( G \) is an atom \( p \) then

\[ J \models FT(p, I) \iff p \in I \text{ and } p \in J \iff I \models FT(p, I)_\perp^J. \]

If \( G \) is \( \neg p \) then both

\[ J \models FT(G, I) \]

and

\[ I \models FT(G, I)_\perp^J \]

are equivalent to \( p \not\in I \). If \( G \) is \( \neg \neg p \) then both

\[ J \models FT(G, I) \]

and

\[ I \models FT(G, I)_\perp^J \]

are equivalent to \( p \in I \).

**Lemma 7** For any simple formula \( G \) and any interpretations \( I \) and \( J \), if \( I \models FT(G, I)_\perp^J \) then \( J \models FT(G, I) \).

**Proof.** It is sufficient to consider the case when \( G \) is a single simple implication \( A^\uparrow \to L^\uparrow \). If \( I \) does not satisfy \( G \) then both \( FT(G, I) \) and \( FT(G, I)_\perp^J \) are \( \perp \). Assume \( I \) satisfies \( G \). Then \( FT(G, I) \) is

\[ FT(A^\uparrow, I) \to FT(L^\uparrow, I). \]

We consider two cases corresponding to whether or not \( A \cap X \setminus I \) is empty. If \( A \cap X \setminus I \) is empty, \( I \not\models FT(A^\uparrow, I) \). Indeed, if it did, \( A \) would be a subset of both \( I \) and \( J \), contradicting the assumption that \( A \cap X \setminus I \) is non-empty. It follows that \( J \models FT(G, I) \). If, on the other hand, \( A \cap X \setminus I \) is empty, then \( FT(G, I)_\perp^J \) is

\[ FT(A^\uparrow, I) \to (FT(L^\uparrow, I))_\perp^J. \]

Assume that \( J \) does not satisfy \( FT(G, I) \). Then

\[ J \models FT(A^\uparrow, I) \text{ and } J \not\models FT(L^\uparrow, I). \]

From the first condition we may conclude that \( I \models FT(A^\uparrow, I) \). (Indeed, if \( J \models FT(A^\uparrow, I) \) then \( A \) must be a subset both of \( I \) and of \( J ) \). From the last condition using Lemma 6 it follows that \( I \not\models FT(L^\uparrow, I)_\perp^J \). We may conclude that \( I \not\models FT(G, I)_\perp^J \).
Proof of Part (a) of Main Lemma. Let $I$ be an FLP-stable model of an FT-tight simple program $\mathcal{H}$. Then $I \models \mathcal{H}$, so that $I \models FT(\mathcal{H}, I)$. We need to show that no proper subset $J$ of $I$ satisfies $FT(\mathcal{H}, I)$. Take a proper subset $J$ of $I$, and let $X = I \setminus J$. By Lemma 4, $I$ does not satisfy $\mathcal{H}^X_I$. Then there is a simple rule $G \rightarrow H$ in $\mathcal{H}$ such that $I$ satisfies $G^X_I$ and does not satisfy $H^X_I$. By Lemma 5, it follows that $I$ satisfies $FT(G, I)^X_I$ and does not satisfy $FT(H, I)^X_I$. Since $X = I \setminus J$, it follows that $J$ satisfies $FT(G, I)$ (Lemma 7) but does not satisfy $FT(H, I)$ (Lemma 6). So $J$ does not satisfy $FT(\mathcal{H}, I)$. It follows that $I$ is FT-stable.

We turn now to the proof of part (b) of Main Lemma. If $F$ is a simple disjunction then by $F^+$ we denote the result of replacing each extended literal $\neg \neg p$ in $F$ by $p$, and similarly for simple implications, formulas, rules, and programs.

Lemma 8 Let $I$ be a model of a simple program $\mathcal{H}$, and let $K$ be a set of atoms such that there are no FLP-critical edges in the subgraph of the dependency graph of $\mathcal{H}$ induced by $K$. If $I \models (\mathcal{H}^+)_{I}^K$, then $I \setminus K$ satisfies the FT-reduct of $\mathcal{H}$ with respect to $I$.

Proof. We need to show that $I \setminus K$ satisfies the FT-reduct of every simple rule $G \rightarrow H$ in $\mathcal{H}$. Since $I$ is a model of $\mathcal{H}$, that reduct is $FT(G, I) \rightarrow FT(H, I)$. If $I \not\models G$ then the antecedent of this implication is equivalent to $\bot$, and the assertion that the implication is satisfied by $I \setminus K$ is trivial.

Assume then that $I \models G$. Since $I$ is a model of $\mathcal{H}$, it follows that $I \models H$. Since $I \models (\mathcal{H}^+)_{I}^K$, either $I \not\models (G^+)^K_I$ or $I \models H^K_I$.

Case 1: $I \models H^K_I$. Then $H$ has a disjunctive term $p$ that belongs to $I$ but not to $K$. Then $p$ is also a disjunctive term in $FT(H, I)$, so that $I \setminus K \models FT(H, I)$. We conclude that $I \setminus K$ satisfies $FT(G \rightarrow H, I)$.

Case 2: $I \not\models (G^+)^K_I$. Consider a conjunctive term $A^\wedge \rightarrow L^\vee$ in $G$ such that $I$ does not satisfy $(A^\wedge \rightarrow (L^\vee)^+)^K_I$. Since $I \models G$, $I \models A^\wedge \rightarrow L^\vee$. It follows that $A^\wedge \cap K = \emptyset$ and that $I$ satisfies $A^\wedge$, $L^\vee$ and $(L^\vee)^+_{I}$ but does not satisfy $(A^\wedge)^+_{I}$.

Case 2.1: $L^\vee$ does not contain any extended literal $\neg \neg p$ such that $p \in K$. Since $I$ satisfies $(L^\vee)^+_{I}$ but not $((L^\vee)^+)^K_I$, each atomic disjunctive term $p$ in $(L^\vee)^+_{I}$ that is in $I$ must also be in $K$. Furthermore, $I$ cannot satisfy any literal $\neg p$ in $\mathcal{L}$. (If it did, then that literal would also be in $(L^\vee)^+_{I}$. This disjunction would be satisfied by $I$.) Since $\mathcal{L}$ does not contain any extended literal $\neg \neg p$ such that $p$ is in $K$, $I$ does not satisfy any extended literal $\neg \neg p$ in $\mathcal{L}$. (For each extended literal $\neg \neg p$ in $\mathcal{L}$, $p$ is a disjunctive term in $(L^\vee)^+_{I}$. If $I$ satisfies some extended literal $\neg \neg p \in \mathcal{L}$, then $I$ would satisfy $p$ and therefore also satisfy $(L^\vee)^+_{I}$. We conclude that every extended literal in $\mathcal{L}$ that is satisfied by $I$ is an atom from $K$. It follows that $FT(L^\vee, I)$ is equivalent to a disjunction of atoms from $K$. So $I \setminus K \not\models FT(L^\vee, I)$. Since $I \models A^\wedge$, $I \models FT(A^\wedge, I)$. Since $\mathcal{A} \cap K$ is empty, $I \setminus K$ also satisfies $FT(A^\wedge)$. We may conclude that $I \setminus K \not\models FT(G, I)$ so that $I \setminus K \not\models FT(G \rightarrow H, I)$.

Case 2.2: $L^\vee$ contains an extended literal $\neg \neg p$ such that $p \in K$. Then no disjunctive term in $\mathcal{L}$ occurs in $K$. (If there were such a disjunctive term $q$ in $\mathcal{L}$ then there would be an FLP-critical edge from $q$ to $p$ in the subgraph of the dependency graph of $\mathcal{H}$ induced by $K$. But the condition of the lemma stipulates that there are no FLP-critical edges in that graph.) Since $I$ satisfies $H$, $I$ satisfies $FT(H, I)$ as well. Since no atoms from $K$ occur in $H$, it follows that $I \setminus K$ satisfies $FT(H, I)$, so that $I \setminus K \models FT(G \rightarrow H, I)$.

Lemma 9 If $\mathcal{H}$ is an FLP-tight simple program and $X$ is a non-empty set of atoms, then there exists a non-empty subset $K$ of $X$ such that in the subgraph of the dependency graph of $\mathcal{H}$ induced by $X$.

(i) there are no edges from $K$ to atoms in $X \setminus K$, and (ii) no atom in $K$ has outgoing FLP-critical edges.

The proof is similar to the proof of Lemma 3.

Lemma 10 If $\mathcal{H}$ is an FLP-tight simple program and $I$ is an FT-stable model of $\mathcal{H}$, then for every non-empty subset $X$ of $I$, $I \not\models (\mathcal{H}^+)_{X}^+$. Proof. Assume on the contrary that $I \models (\mathcal{H}^+)_{X}^+$ for some non-empty subset $X$ of $I$. Consider a non-empty subset $K$ of $X$ meeting conditions (i) and (ii) from Lemma 9. Since $I \models (\mathcal{H}^+)_{X}^+$ and $K$ satisfies (i), by Lemma 1 we may conclude that $I \models (\mathcal{H}^+)_{K}^+$. Since $K$ satisfies (ii) and is a subset of $X$, there are no FLP-critical edges in the subgraph of the dependency graph of $\mathcal{H}$ induced by $K$. So by Lemma 8, $I \setminus K$ satisfies the FT-reduct of $\mathcal{H}$, contradicting the assumption that $I$ is FT-stable.

Lemma 11 Let $G$ be a simple disjunction or a simple formula. For any interpretations $I$ and $J$ such that $J \subseteq I$, if $I \models (G^+)_{\bigcap J}^+$ then $J \models G$.

Proof. To prove the assertion of the lemma for simple disjunctions, it is sufficient to consider the case when $G$ is a single extended literal. If $G$ is $p$ or $\neg \neg p$ then $(G^+)_{\bigcap J}^+$ is $p_{\bigcap J}^+$. Since $I$ satisfies this formula, $p \in J$, so that $J \models G$. If $G$ is $\neg \neg p$ then $(G^+)_{\bigcap J}^+$ is $\neg \neg p$. Since $I \models \neg \neg p$ and $J \subseteq I$, $J \models \neg \neg p$.

To prove the assertion of the lemma for simple formulas, it is sufficient to consider the case when $G$ is a single simple implication $A^\wedge \rightarrow L^\vee$. If $A \cap I \setminus J$ is non-empty then $J \not\models A^\wedge$, so that $J \models G$. If, on the other hand, $A \cap I \setminus J$ is empty then $(G^+)_{\bigcap J}^+$ is $A^\wedge \rightarrow (L^\vee)^+_{\bigcap J}$. Assume that $J$ does not satisfy $G$. Then $J \models A^\wedge$ and $J \not\models L^\vee$.

From the first condition and the fact that $J \subseteq I$ we may conclude that $I \models A^\wedge$. From the second condition it follows, by the part of the lemma proved above, that $I \not\models ((L^\vee)^+)^+_{\bigcap J}$. Consequently $I \not\models (G^+)_{\bigcap J}^+$.

Proof of Part (b) of Main Lemma. Let $I$ be a FT-stable model of an FLP-tight simple program $\mathcal{H}$. Then $I$ is a model
of \( \mathcal{H} \), and consequently a model of the reduct \( FLP(\mathcal{H}, I) \).

We need to show that no proper subset \( J \) of \( I \) is a model of this reduct. Consider a proper subset \( J \) of \( I \), and let \( X \) be \( I \setminus J \). By Lemma 10, \( I \) does not satisfy \( \mathcal{H}^+ \). Then there is a simple rule \( G \rightarrow H \) in \( \mathcal{H} \) such that \( I \) satisfies \( (G^+)^X \) but \( H \) does not satisfy \( H^X \). Since \( G \) entails \( G^+ \), and \( G^+ \) is equivalent to \( G \), we can conclude that \( I \) satisfies \( G \), so that \( G \rightarrow H \) belongs to the reduct \( FLP(\mathcal{H}, I) \). On the other hand, by Lemma 11, \( J \) satisfies \( G \). Since \( I \) does not satisfy \( H \), and \( H \) is a disjunction of atoms, \( J \) does not satisfy \( H \). So \( J \) does not satisfy \( G \rightarrow H \), and consequently is not a model \( FLP(\mathcal{H}, I) \).

**Proof of Main Theorem**

Consider a program \( \Pi \) in the programming language described at the beginning of this paper. Every formula in \( \tau \Pi \) corresponds to one of the rules (8) of \( \Pi \) and has the form

\[
\tau((B_1, \ldots, B_n)_\mathbf{x}) \rightarrow \tau(H_1)_\mathbf{x} \lor \cdots \lor \tau(H_k)_\mathbf{x}
\]  

(19)

where \( \mathbf{x} \) is the list of all global variables of the rule, and \( \mathbf{r} \) is a tuple of precomputed terms such that all literals \( (H_i)_\mathbf{r} \), \( (B_j)_\mathbf{r} \) are well-formed. The consequent of (19) is a disjunction of atoms over the signature \( \sigma_0 \) the set of atoms of the form \( p(t) \), where \( p \) is a symbolic constant and \( t \) is a tuple of precomputed terms. The antecedent of (19) is a conjunction of formulas of three types:

(i) literals over \( \sigma_0 \)—each of them is \( \tau(L^x_p) \) for some symbolic literal \( L \) from the body of the rule;

(ii) implications of form (14)—each of them is \( \tau(E^x_r) \) for some aggregate literal \( E \) from the body of the rule;

(iii) negations of such implications—each of them is \( \neg \tau(E^x_r) \) for some aggregate literal \( E \) from the body of the rule.

Each of the formulas \( \tau(L^x_p) \) in (14) is a conjunction of literals over \( \sigma_0 \). It follows that (14) can be represented in the form

\[
(A_1) \land \bigwedge_{p \in A_2} \neg p \rightarrow C^\forall,
\]  

(20)

where \( A_1 \) and \( A_2 \) are sets of atoms from \( \sigma_0 \), and \( C \) is a set of conjunctions of literals over \( \sigma_0 \).

Consider the simple program \( \mathcal{H} \) obtained from \( \tau \Pi \) by transforming the conjunctive terms of the antecedents of its formulas (19) as follows:

- Every literal \( L \) is replaced by the simple implication

\[
\top \rightarrow L.
\]  

(21)

- Every implication (20) is replaced by the simple formula

\[
\phi \left( (A_1) \land \bigvee_{p \in A_2} \neg p \lor \bigvee_{C \in C} \phi(C) \right),
\]  

(22)

where the big conjunction extends over all functions \( \phi \) that map every non-empty conjunction from \( C \) to one of its conjunctive terms.

- Every negated implication (20) is replaced by the simple formula

\[
\bigwedge_{p \in A_1} (\top \rightarrow p) \land \bigwedge_{p \in A_2} (\top \rightarrow \neg p) \lor \bigvee_{C \in C} L \text{ is a conjunctive term of } C.
\]  

(23)

Each conjunctive term of the antecedent of (19) is equivalent to the simple formula that replaces it in \( \mathcal{H} \). It follows that \( \tau \Pi \) and \( \Pi \) have the same FLP-stable models. On the other hand, \( \tau \Pi \) and \( \Pi \) have the same models in the infinitary logic of here-and-there, and consequently the same FT-stable models. Consequently, the FLP-stable models of \( \Pi \) can be characterized as the FLP-stable models of \( \mathcal{H} \) and the FT-stable models of \( \Pi \) can be characterized as the FT-stable models of \( \mathcal{H} \).

To derive the main theorem from the main lemma, we will establish two claims that relate the predicate dependency graph of \( \Pi \) to the dependency graph of \( \mathcal{H} \):

**Claim 1.** If there is an edge from an atom \( p(t_1, \ldots, t_k) \) to an atom \( q(s_1, \ldots, s_l) \) in the dependency graph of \( \mathcal{H} \), then there is an edge from \( p/k \) to \( q/l \) in the dependency graph of \( \Pi \).

**Claim 2.** If the edge from \( p(t_1, \ldots, t_k) \) to \( q(s_1, \ldots, s_l) \) in the dependency graph \( \mathcal{H} \) is FT-critical or FLP-critical then \( \Pi \) contains a rule (8) such that

- \( p/k \) is the predicate symbol of one of the atoms \( H_i \), and

- \( q/l \) is the predicate symbol of an atom occurring in one of the non-positive aggregate literals \( B_j \).

Using these claims, we will show that if the dependency graph of \( \mathcal{H} \) has a path with infinitely many FT-critical edges or infinitely many FLP-critical edges, then we can find a non-positive aggregate literal recursive with respect to \( \Pi \). The assertion of the theorem will immediately follow then by Main Lemma.

Assume that \( p_1(t^1), p_2(t^2), \ldots \) is a path in the dependency graph of \( \mathcal{H} \) that contains infinitely many FT-critical edges (or FLP-critical edges, the reasoning is the same). By Claim 1, the sequence \( p_1/k_1, p_2/k_2, \ldots \), where \( k_i \) is the length of \( t^i \), is a path in the predicate dependency graph of \( \Pi \). Since that graph is finite, there exists a positive integer \( a \) such that all vertices \( p_a/k_a, p_{a+1}/k_{a+1}, \ldots \) belong to the same strongly connected component. Since the path \( p_1(t^1), p_2(t^2), \ldots \) contains infinitely many FT-critical edges, there exists a \( b \geq a \) such that the edge from \( p_b(t^b) \) to \( p_{b+1}(t^{b+1}) \) is FT-critical. By Claim 2, it follows that \( \Pi \) contains a rule (8) such that \( p_b/k_b \) is the predicate symbol of one of the atoms \( H_i \), and \( p_{b+1}/k_{b+1} \) is the predicate symbol of an atom occurring in one of the non-positive aggregate literals \( B_j \). Since \( p_b/k_b \) and \( p_{b+1}/k_{b+1} \) belong to the same strongly connected component, there exists a path from \( p_b/k_b \) to \( p_{b+1}/k_{b+1} \). It follows that \( B_i \) is recursive with respect to \( \Pi \).

**Proof of Claim 1.** If there is an edge from \( p(t_1, \ldots, t_k) \) to \( q(s_1, \ldots, s_l) \) in the dependency graph of \( \mathcal{H} \) then \( \Pi \) contains
a rule (8) such that \( p(t_1, \ldots, t_k) \) occurs in the consequent of one of the implications (19) corresponding to this rule, and 
\( q(s_1, \ldots, s_l) \) occurs in one of the formulas (21)–(23). Then 
\( q(s_1, \ldots, s_l) \) occurs also in the antecedent of (19). It follows that 
\( p/k \) is the predicate symbol of one of the atoms occurring in 
the head of the rule, and \( q/l \) is the predicate symbol of one 
of the atoms occurring in its body.

Proof of Claim 2. If the edge from \( p(t_1, \ldots, t_k) \) to 
\( q(s_1, \ldots, s_l) \) in the dependency graph of \( \mathcal{H} \) is FLP-critical 
then \( \mathcal{H} \) contains a rule (8) such that \( p(t_1, \ldots, t_k) \) occurs in 
the consequent of one of the implications (19) corresponding 
to this rule, and \( q(s_1, \ldots, s_l) \) occurs strictly positively in one 
of the non-positive conjunctive terms \( A^> \rightarrow \mathcal{L'} \) of one 
of the simple conjunctions (21)–(23). If a formula of form (21) 
is non-positive then no atoms occur in it strictly positively. Consequently 
\( A^> \rightarrow \mathcal{L'} \) is a conjunctive term of one of the 
formulas (22) or (23), and it corresponds to an aggregate literal 
from the body of the rule. That aggregate literal is not positive, 
because for any positive literal \( E \) no conjunctive 
term of the corresponding simple conjunction (22) is non-positive. It follows that 
\( p/k \) is the predicate symbol of one of the atoms 
in the head of the rule, and \( q/l \) is the predicate symbol 
of an atom from a non-positive aggregate literal in 
the body.

For FLP-critical edges the reasoning is similar, using 
the fact that formulas of form (21) do not contain double negations, 
and neither do formulas of form (22) corresponding to 
positive aggregate literals.

Related Work

The equivalence between the FLP and FT approaches to 
defining stable models for programs without aggregates was 
established by Faber, Leone, and Pfeifer (2004), Theorem 3. 
The fact that this equivalence is not destroyed by the use 
of positive aggregates was proved by Ferraris (2005), Theorem 3. 
That result is further generalized by Bartholomew, Lee, and Meng (2011), Theorem 7.

The program

\[
q(\overline{1}), \quad r \leftarrow \text{count}\{X : not p(X), \ q(X)\} = \overline{1}
\]

has no recursive aggregates but is not covered by any of the 
results quoted above because it contains a negative literal in 
the conditions of an aggregate atom.

Conclusion

An oversight in the semantics proposed in the ASP-Core 
document can be corrected using a translation into the 
language of infinitary propositional formulas. The main theorem 
of this paper describes conditions when stable models 
are identical to stable models in the sense of the input language 
of CLINGO.

The main lemma asserts that if a set of infinitary propositional 
formulas is FT-tight then its FLP-stable models are 
FT-stable, and if it is FLP-tight then its FT-stable models are 
FLP-stable.

Acknowledgements

Martin Gebser made a valuable contribution to our work by 
pointing out an oversight in an earlier version of the proof 
and suggesting a way to correct it. We are grateful to Wolfgang 
Faber, Jorge Fandiño, Michael Gelfond, and Yuanlin Zhang for useful discussions related to the topic of this paper, 
and to the anonymous referees for their comments. This research was partially supported by the National Science 
Foundation under Grant IIS-1422455.
