Core Motion
Core Motion

*Core Motion* is a framework that allows your application to receive motion data from device hardware.

For an iOS developer, this means you can create applications that can observe and respond to the motion and orientation of an iOS device.

**Important note:**

You can only test or use the functionality of Core Motion on an actual device. The simulator does not have any facilities for reproducing physical motion for your app.
Accelerometer
• Measures acceleration in all three dimensions

Gyroscope
• Calculates orientation and rotation in all three dimensions

Magnetometer
• Measures magnetic forces
Coordinate System

+x is towards the right of the screen

+y is towards the top of the screen

+z is towards the user when the screen is faceup
Rotations Within the Coordinate System

*Pitch*: rotation around the x axis

*Roll*: rotation around the y axis

*Yaw*: rotation around the z axis
A **CMDeviceMotion** object contains the following objects as properties:

- **attitude**: **CMAttitude**
  - Returns the orientation of the device
  - Can access the data in any of 3 representations

- **rotationRate**: **CMRotationRate**
  - Returns the rotation rate of the device for devices with a gyro
  - x, y, z values in radians per second

- **gravity**: **CMAcceleration**
  - Returns the gravity vector expressed in the device's reference frame
  - x, y, z values in g’s (gravitational force)

- **userAcceleration**: **CMAcceleration**
  - Returns the acceleration that the user is giving to the device
  - x, y, z values in g’s (gravitational force)

- **magneticField**: **CMCalibratedMagneticField**
  - Returns the magnetic field vector with respect to the device for devices with a magnetometer
CMAAttitude contains three different representations of the device’s orientation:

- Euler angles (pitch, roll, yaw)
- Rotation matrices
- Quaternions

Each of these is in relation to a given reference frame.
Euler Angles are the most readily understood of the 3 representations, as they simply describe rotation around each of the axes.

- **Pitch** - is rotation around the \textit{x-axis}, increasing as the device tilts toward you, decreasing as it tilts away

- **Roll** - is rotation around the \textit{y-axis}, decreasing as the device rotates to the left, increasing to the right

- **Yaw** - is rotation around the \textit{z-axis}, decreasing clockwise, increasing counter-clockwise
CMMotionManager provides a consistent interface for each of the four motion data types:

- Attitude (rotation)
- Acceleration
- Gravity
- Magnetic Field

Although you can access data for each of these motion types individually, it’s simplest to create a CMMotionManager instance to access all of the above.
If `deviceMotion` is a `CMDeviceMotion` object:

```javascript
deviceMotion.gravity.x
deviceMotion.gravity.y
deviceMotion.gravity.z

deviceMotion.userAcceleration.x
deviceMotion.userAcceleration.y
deviceMotion.userAcceleration.z

deviceMotion.attitude.pitch
deviceMotion.attitude.roll
deviceMotion.attitude.yaw

deviceMotion.magneticField.field.x
deviceMotion.magneticField.field.y
deviceMotion.magneticField.field.z
```
Using Core Motion in Your App

1. Create a motion manager:

In your ViewController class:

```swift
let motionManager = CMMotionManager()
```
Using Core Motion in Your App

2. Start receiving updates at the desired frequency:

```swift
override func viewDidLoad() {
    super.viewDidLoad()

    motionManager.deviceMotionUpdateInterval = 0.1

    motionManager.startDeviceMotionUpdates(to: OperationQueue.current!) {
        (deviceMotion: deviceMotion, error) -> Void in
            if(error == nil) {
                // you write these methods
                self.handleUpdate(deviceMotion: deviceMotion)
            } else {
                self.handleError()
            }
    }
}
```
Using Core Motion in Your App

3. Write code specifying what you want to happen at each update

```swift
func handleUpdate(deviceMotion: CMDeviceMotion) {

    let acceleration = deviceMotion.userAcceleration
    let xAcc = acceleration.x
    let yAcc = acceleration.y
    let zAcc = acceleration.z

    print("Acceleration in the x direction: \(xAcc)")
    print("Acceleration in the y direction: \(yAcc)")
    print("Acceleration in the z direction: \(zAcc)")
}

func handleError() {
    print("An error occurred")
```
