\section*{Abstract}
Distributional data tells us that a man can swallow candy, but not that a man can swallow a paintball, since this is never attested. However both are physically plausible events. This paper introduces the task of semantic plausibility: recognizing plausible but possibly novel events. We present a new crowdsourced dataset of semantic plausibility judgments of single events such as “man swallow paintball”. Simple models based on distributional representations perform poorly on this task, despite doing well on selection preference, but injecting manually elicited knowledge about entity properties provides a substantial performance boost. Our error analysis shows that our new dataset is a great testbed for semantic plausibility models: more sophisticated knowledge representation and propagation could address many of the remaining errors.

\begin{table}

-man-swallow-* & PREFERRED? & PLAUSIBLE? \\
\hline
-candy & $\checkmark$ & $\checkmark$ \\
-paintball & $\times$ & $\checkmark$ \\
-desk & $\times$ & $\times$ \\
\hline
\end{tabular}
\caption{Distinguishing Semantic Plausibility from Selectional Preference. candy is selectionally preferred because it is distributionally common patient in the event man-swallow-*, as opposed to the bizarre and rarely seen (if at all) patient paintball. However both are semantically plausible according to our world knowledge: they are small-sized objects that are swallowable by a man. desk is both distributionally unlikely and implausible (i.e. oversized for swallowing).}
\end{table}

\section{1 Introduction}
Intuitively, a man can swallow a candy or paintball but not a desk. Equally so, one cannot plausibly eat a cake and then hold it. What kinds of semantic knowledge are necessary for distinguishing a physically plausible event (or event sequence) from an implausible one? Semantic plausibility stands in stark contrast from the familiar selectional preference (Erk and Padó, 2010; Van de Cruys, 2014) which is concerned with the typicality of event(s) (Table 1). For example, candy is a typical entity for man-swallow-* but paintball is not, even though both events are plausible physically. Also, some events are physically plausible but are never stated because humans avoid stating the obvious. Critically, semantic plausibility is sensitive to certain properties such as relative object size that are not explicitly encoded by selectional preferences (Bagherinezhad et al., 2016). Therefore, it is crucial that we learn to model these dimensions in addition to using classical distributional signals.

Semantic plausibility is pertinent and crucial in a multitude of interesting NLP tasks put forth previously, such as narrative schema (Chambers, 2013), narrative interpolation (Bowman et al., 2016), story understanding (Mostafazadeh et al., 2016), and paragraph reconstruction (Li and Jurafsky, 2017). Existing methods for these tasks, however, draw predominantly (if not only) on distributional data and produce rather weak performance. Semantic plausibility over subject-verb-object triples, while simpler than these other tasks, is a key building block that requires many of the same signals and encapsulates complex world knowledge in a binary prediction problem.

In this work, we show that world knowledge injection is necessary and effective for the semantic plausibility task, for which we create a robust, high-agreement dataset (details in section 3). Employing methods inspired by the recent work on world knowledge propagation through distributional context (Forbes and Choi, 2017; Wang et al., 2017), we accomplish the goal with minimal effort in manual annotation. Finally, we perform an in-
depth error analysis to point to future directions of work on semantic plausibility.

2 Related Work

Simple events (i.e. S-V-O) have seen thorough investigation from the angle of selectional preference. While early works are resource-based (Resnik, 1996; Clark and Weir, 2001), later work shows that unsupervised learning with distributional data yields strong performance (O’Seaghdha, 2010; Erk and Padó, 2010), which has recently been further improved upon with neural approaches (Van de Cruys, 2014; Tilk et al., 2016). Distribution-only models however, as will be shown, fail on the semantic plausibility task we propose.

Physical world knowledge modeling appears frequently in more closely related work. Bagherinezhad et al. (2016) combine computer vision and text-based information extraction to learn the relative sizes of objects; Forbes and Choi (2017) crowdsource physical knowledge along specified dimensions and employ belief propagation to learn relative physical attributes of object pairs. Wang et al. (2017) propose a multimodal LDA to learn the definitional properties (e.g. animal, four-legged) of entities. However, no prior work handles the semantic plausibility task and even related efforts do not necessarily adapt well to this task, as we will show, suggesting that new approaches are needed.

3 Data

To study the semantic plausibility of S-V-O events, specifically physical semantic plausibility, we create a dataset\(^1\) through Amazon Mechanical Turk with the following criteria in mind: (i) Robustness: Strong inter-annotator agreement; (ii) Diversity: A wide range of typical/atypical, plausible/implausible events; (iii) Balanced: Equal number of plausible and implausible events.

In creating physical events, we work with a fixed vocabulary of 150 concrete verbs and 450 concrete nouns from Brysbaert et al. (2014)’s word list, with a concreteness threshold of 4.95 (scale: 0-5). We take the following steps:

(a) Have Turkers write down plausible or implausible S-V and V-O selections;

(b) Randomly generate S-V-O triples from collected S-V and V-O pairs;

(c) Send resulting S-V-O triples to Turkers to filter for ones with high agreement (by majority vote).

(a) ensures diversity and the cleaness of data (compared with noisy selectional preference data collected unsupervised from free text): the Turkers are instructed (with examples) to (i) consider both typical and atypical selections (e.g. man-swallow-\(*) with candy or paintball); (ii) disregard metaphorical uses (e.g. feel-blue or fish-idea).

2,000 pairs are collected in the step, balancing typical & atypical pairs. In (b), we manually filter error submissions in triple generation. For (c), 5 Turkers provide labels, and we only keep the ones that have \(\geq 3\) majority votes, resulting with 3,062 triples (of 4,000 annotated triples, plausible-implausible balanced), with \(100\% \geq 3\) agreement, \(95\% \geq 4\) agreement, and \(90\% \geq 5\) agreement.

To empirically show the failure of distribution-only methods, we run Van de Cruys (2014)’s neural net classifier (hereafter NN), which is one of the strongest models designed for selectional preference (Figure 1, left-box). Let \(x\) be the concatenation of the embeddings of the three words in an S-V-O. The prediction \(\hat{y}\) is computed as follows:

\[
\hat{y} = \arg\max_y \text{softmax}(\sigma(W_2\sigma(W_1x)))
\]

where \(\sigma, W\) are nonlinearity and weights, and we use 300D pretrained GloVe vectors (Pennington et al., 2014). The model achieves an accuracy of 68% (logistic regression baseline: 64%) after fine-tuning, verifying the intuition that distributional data alone cannot satisfactorily capture the semantics of physical plausibility.

4 World Knowledge Features

Recognizing that a distribution-alone method lacks necessary information, we collect a set of world knowledge features. The feature types derive from inspecting the high agreement event triples for knowledge missing in distributional selection (e.g. relative sizes in man-swallow-paintball/desk). Previously, Forbes and Choi (2017) proposed a three level (3-LEVEL) featureization scheme, where an object-pair can take 3 values for, e.g. relative size: \\{−1, 0, 1\} (i.e. lesser, similar, greater). This method, however, does not

\(^1\)Link: https://github.com/suwancompling/Modeling-Semantic-Plausibility-NAACL18/tree/master/data.
explain many cases we observed. For instance, man-hug-cat/ant, man is larger than both cat and ant, but the latter event is implausible. 3-LEVEL is also inefficient: \( k \) objects incur \( O(k^2) \) elicitation. We thus propose a binning-by-landmark method, which is sufficiently fine-grained, efficient and easy for the annotator: given an entity \( n \), the Turker decides to which of the landmarks \( n \) is closest to. E.g., for SIZE, we have the landmarks \{watch, book, cat, person, jeep, stadium\}, in ascending sizes. If \( n = \) dog, the Turker may put \( n \) in the bin corresponding to cat. The features\(^2\) are listed with their landmarks as follows:

- **SENTENCE**: rock, tree, ant, cat, chimp, man.
- **MASS-COUNT**: milk, sand, pebbles, car.
- **PHASE**: smoke, milk, wood.
- **SIZE**: watch, book, cat, person, jeep, stadium.
- **WEIGHT**: watch, book, dumbbell, man, jeep, stadium.
- **RIGIDITY**: water, skin, leather, wood, metal.

5 Turkers provide annotations for all 450 nouns, and we obtained 93% \( \geq 3 \) agreement, 85% \( \geq 4 \) agreement, and 79% \( \geq 5 \) agreement.

Our binning is sufficiently granular, which is crucial for semantic plausibility of an event in many cases. E.g. for man-hug-cat/ant, man, cat and ant fall in the 4\textsuperscript{th}, 3\textsuperscript{rd} and 1\textsuperscript{st} bin, which suffices to explain why man-hug-cat is plausible while man-hug-ant is not. Compared to past work, it is efficient (Forbes and Choi, 2017). Each entity only needs one assignment in comparison to the landmarks to be located in a “global scale” (e.g. from the smallest to the largest objects), and even for extreme granularity, it only takes \( O(k \log k) \) comparisons. It is also intuitive: differences in bins capture the intuition that one can hug smaller objects as long as those objects are not too small.

5 Models

We answer two questions: (i) Does world knowledge improve the accuracy of semantic plausibility classification? (ii) Can we minimize effort in knowledge feature annotation by learning from a small amount of training data?

For question (i), we experiment with various methods to incorporate the features on top of the embedding-only NN (Section 3). Our architecture\(^3\) is outlined in Figure 1, where we ensemble the NN (left-box) and another feedforward net for features (WK, right-box) to produce the final prediction. For the feature net, the relative physical attributes of the subject-object pair can be encoded in 3-LEVEL (Section 4) or the bin difference (BIN-DIFF) scheme.\(^4\) For BIN-DIFF, given the two entities in an S-V-O event (i.e. S, O) ant and man, which are in the bins of the landmark watch (i.e. the 1\textsuperscript{st}) and that of person (i.e. the 4\textsuperscript{th}), the pair ant-man gets a BIN-DIFF value of \( 1 - 4 = -3 \). Exemplifying the featurization function \( f(s, o) \) with SIZE:

\[
\begin{align*}
 f_{3-L}(\text{SIZE}(s), \text{SIZE}(o)) &\in \{-1, 0, 1\} \quad (2) \\
 f_{\text{BIN}}(\text{SIZE}(s), \text{SIZE}(o)) &= \text{BIN}(s) - \text{BIN}(o) \quad (3)
\end{align*}
\]

Then, given a featurization scheme, we may feed raw feature values (RAW VEC, for 3-LEVEL, e.g. concatenation of -1, 0 or 1 of all feature types, in that order, and in one-hot format), or feature embeddings (EMBEDDING, e.g. concatenation of embeddings looked up with feature values). Finally, let \( \alpha_{\text{NN}}, \alpha_{\text{WK}} \) be the penultimate-layer vectors of NN and WK (see Figure 1), we affine transform their concatenation to predict label \( \hat{y} \) with

\(^2\)We experimented with numerous feature types, e.g. size, temperature, shape, etc. and kept the subset that contributes most substantially to semantic plausibility classification. More details on the feature types in supplementary material (https://github.com/suwangcompling/Modeling-Semantic-Plausibility-NAACL18/tree/master/supplementary).

\(^3\)More configuration details in supplementary material.

\(^4\)We also tried using bin numbers directly, however it does not produce ideal results (classification accuracy between 3-LEVEL and BIN-DIFF). Thus for brevity we drop this setup.
argmax on the final softmax layer:

$$\hat{y} = \text{argmax} \text{softmax}(\sigma(W[a_{NN}, a_{WK}] + b))$$

where $\sigma$ is a ReLU nonlinearity. We will only report the results from the best-performing model configuration, which has BIN-DIFF + EMBED-DING. The model will be listed below as NN + WK-GOLD (i.e. with GOLD, Turker-annotated world knowledge features).

For question (ii), we select a data-efficient feature learning model. Following Forbes and Choi (2017) we evaluate the models with 5% or 20% of training data. We experiment with several previously proposed techniques: (a) label spreading; (b) factor graph; (c) multi-LDA. As a baseline we employ a simple but well-tuned logistic regressor (LR). We also initialize the factor graph with this LR, on account of its unexpectedly strong performance.\(^5\) Finally, observing that the feature types are inherently ordinal (e.g. SIZE from small to large), we also run ordinal logistic regression (Adeleke and Adepoju, 2010). For model selection we first evaluate the object-pair attribute data collected by Forbes and Choi (2017), 2.5k pairs labeled in the 3-LEVEL scheme. We then compared the the LR and Ordinal-LR (our strongest models\(^6\)) on 10k randomly generated object-pairs from our annotated nouns. The results are summarized in Table 2, where we see (i) 3-LEVEL propagation is much easier; (ii) our object-pairs are more challenging, likely due to sparsity with larger vocabulary size; (iii) ordinal-

\(^5\)We verified our setup with the authors and they attributed the higher performance of our LR to hyperparameter choices.

\(^6\)Because the factor graph + LR gives very slight improvement, for simplicity we choose LR instead.

The average of 10-fold CV (splitting on the total 3,062 entries). The neural classifier injected with full annotation of world knowledge (i.e. NN + WK-GOLD) performs substantially better, and the performance retention is rather strong with propagated features (by Ordinal-LR) from small fractions of gold annotation (i.e. in NN + WK-PROP).

### 6 Semantic Plausibility Results

We evaluate the models on the task of classifying our 3,062 s-v-o triples by semantic plausibility (10-fold CV, taking the average over 20 runs with the same random seed). We compare our three models in the 3-LEVEL and BIN-DIFF schemes, with NN + WK-PROP evaluated in 5% and 20% training conditions. The results are outlined in Table 3. Summarizing our findings: (i) world knowledge undoubtedly leads to strong performance boost (~8%); (ii) BIN-DIFF scheme works much better than 3-LEVEL — it manages to outperform the latter even with much weaker propagation accuracy; (iii) the accuracy loss with propagated features seems rather mild with 20% labeled training and the best scheme.

### 7 Error Analysis

To understand the still-low 76% accuracy, we run the models above 200 times (10-fold CV, random shuffle at each run), and inspect the top 200 most frequently misclassified cases. The percentage statistics below are from counting the error cases.

In the cases where NN misclassifies while NN + WK-GOLD correctly classifies, ~60% relates to SIZE and WEIGHT (e.g. missing man-hug-ant (bad) or dog-pull-paper (good)). PHASE takes up ~18% (e.g. missing monkey-puff-smoke (good)). This validates the intuition that distributional contexts do not encode the types of world knowledge.
For cases often misclassified by all the models, we observe two main types of errors: (i) data sparsity; (ii) highly-specific attributes.

**Data sparsity (32%).** *man-choke-ant*, e.g., is a singleton big-object-choke-small-object instance, and there are no distributionally similar verbs that can help (e.g. *suffocate*); For *sun-heat-water*, because the majority of the actions in the data are limited to solid objects, the models tend to predict implausible for whenever a gas/liquid appears as the object.

**Highly-specific attributes (68%).** “long-tailed” physical attributes which are absent from our feature set are required. To exemplify a few:

- **edibility (21%).** *-fry-egg* (plausible) and *-fry-cup* (implausible) are hard to distinguish because *egg* and *cup* are similar in size/weight/..., however introducing large free-text data to help learn edibility misguides our model to mind selectional preference, causing mislabeling of other events.
- **natural vs. artificial (18%).** Turkers often think creating natural objects like *moon* or *mountain* is implausible but creating an equally big (but artificial) object like *skyscraper* is plausible.
- **hole objects (15%).** *plane-contain-shell* and *purse-contain-scissors* are plausible, but the hollow-object-can-contain-things attribute is failed to be captured.
- **forefoot dexterity (5%).** *horse-hug-man* is implausible but *bear-hug-man* is plausible; For *-snatch-watch*, *girl* is a plausible subject, but not *pig*. Obviously the dexterity of the forefoot of the agent matters here.

The analysis shows that the task and the dataset highlights the necessity for more sophisticated knowledge featurization and cleverer learning techniques (e.g. features from computer vision, propagation methods with stronger capacity to generalize) to reduce the cost of manual annotation.

### 8 Conclusion

We present the novel task of *semantic plausibility*, which forms the foundation of various interesting and complex NLP tasks in event semantics (Bowman et al., 2016; Mostafazadeh et al., 2016; Li and Jurafsky, 2017). We collected a high-quality dedicated dataset, showed empirically that the conventional, distribution data only model fails on the task, and that clever world knowledge injection can help substantially with little annotation cost, which lends initial empirical support for the scalability of our approach in practical applications, i.e. labeling little but propagating well approximates performance with full annotation. Granted that annotation-based injection method does not cover the full spectrum of leverageable world knowledge information (alternative/complementary sources being images and videos, e.g. Bagherinezhad et al. 2016), it is indeed irreplaceable in some cases (e.g. features such as weight or rigidity are not easily learnable through visual modality), and in other cases presents a low-cost and effective option. Finally, we also discovered the limitation of existing methods through a detailed error analysis, and thereby invite cross-area effort (e.g. multimodal knowledge features) in the future exploration in automated methods for semantic plausibility learning.
