

Intermediate Code

1

Summary: Semantic Analysis

- Check errors not detected by lexical or syntax analysis
- Scope errors:
 - Variables not defined
 - Multiple declarations
- Type errors:
 - Assignment of values of different types
 - Invocation of functions with different number of parameters or parameters of incorrect type
 - Incorrect use of return statements

Introduction to Compilers

2

Semantic Analysis

- Type checking
 - Use type checking rules
 - Static semantics = formal framework to specify type-checking rules
- There are also control flow errors:
 - Must verify that a **break** or **continue** statement is always enclosed by a while (or for) statement
 - Java: must verify that a **break X** statement is enclosed by a for loop with label X
 - Can easily check control-flow errors by recursively traversing the AST

Intermediate Code

- Usually two IRs:

High-level IR

- Tree node structure, essentially ASTs
- High-level constructs common to many languages
 - Expression nodes
 - Statement nodes
- Expression nodes for:
 - Integers and program variables
 - Binary operations: $e1 \text{ OP } e2$
 - Arithmetic operations
 - Logic operations
 - Comparisons
 - Unary operations: $\text{OP } e$
 - Array accesses: $e1[e2]$

High-level IR

- Statement nodes:
 - Block statements (statement sequences): $(s1, \dots, sN)$
 - Variable assignments: $v = e$
 - Array assignments: $e1[e2] = e3$
 - If-then-else statements: $\text{if } c \text{ then } s1 \text{ else } s2$
 - If-then statements: $\text{if } c \text{ then } s$
 - While loops: $\text{while } (c) \ s$
 - Function call statements: $f(e1, \dots, eN)$
 - Return statements: return or $\text{return } e$
- May also contain:
 - For loop statements: $\text{for}(v = e1 \text{ to } e2) \ s$
 - Break and continue statements
 - Switch statements: $\text{switch}(e) \{ v1: s1, \dots, vN: sN \}$

Low-Level IR

- Low-level representation is essentially an instruction set for an abstract machine
- Alternatives for low-level IR:
 - Three-address code or quadruples (Dragon Book):
 $a = b \text{ OP } c$
 - Tree representation (Tiger Book)
 - Stack machine (like Java bytecode)

Three-Address Code

- In this class: **three-address code**
 $a = b \text{ OP } c$
- Has at most three addresses (may have fewer)
- Also named **quadruples** because can be represented as:
(a, b, c, OP)
- Example:
 $a = (b+c)*(-e);$ $t1 = b + c$
 $t2 = -e$
 $a = t1 * t2$

Low IR Instructions

- Assignment instructions:
 - Binary operations: $a = b \text{ OP } c$
 - arithmetic: ADD, SUB, MUL, DIV, MOD
 - logic: AND, OR, XOR
 - comparisons: EQ, NEQ, LT, GT, LEQ, GEQ
 - Unary operation $a = \text{OP } b$
 - Arithmetic MINUS or logic NEG
 - Copy instruction: $a = b$
 - Load /store: $a = *b, *a = b$
 - Other data movement instructions

Low IR Instructions, cont.

- Flow of control instructions:
 - label L : label instruction
 - jump L : Unconditional jump
 - cjump a L : conditional jump
- Function call
 - call $f(a_1, \dots, a_n)$
 - $a = \text{call } f(a_1, \dots, a_n)$
 - Is an extension to quads
- ... IR describes the Instruction Set of an abstract machine

Example

```
m = 0;
if (c == 0) {
    m = m + n*n;
} else {
    m = m + n;
}
```

```
m = 0
t1 = (c == 0)
fjump t1 falseb
t2 = n * n
m = m + t2
jump end
label falseb
m = m+n
label end
```

How To Translate?

- May have nested language constructs
 - Nested if and while statements
- Need an algorithmic way to translate
- Solution:
 - Start from the AST representation
 - Define translation for each node in the AST in terms of a (recursive) translation of its constituents

Notation

- Use the notation $T[e]$ = low-level IR of high-level IR construct e
- $T[e]$ is sequence of low-level IR instructions
- If e is expression (or statement expression), $T[e]$ represents a value
- Denote by $t = T[e]$ the low-level IR of e , whose result value is stored in t
- For variable v , define $T[v]$ to be v , i.e., $t = T[v]$ is copy instruction $t = v$

Translating Expressions

- Binary operations: $t = T[e1 \text{ OP } e2]$
(arithmetic operations and comparisons)

$t1 = T[e1]$

$t2 = T[e2]$

$t = t1 \text{ OP } t2$

- Unary operations: $t = T[OP \ e]$

$t1 = T[e]$

$t = OP \ t1$

Translating Boolean Expressions

- $t = T[e1 \text{ OR } e2]$

$t1 = T[e1]$

$t2 = T[e2]$

$t = t1 \text{ OR } t2$

- ... but how about short-circuit OR, for which we should compute $e2$ only if $e1$ evaluates to false

Translating Short-Circuit OR

- Short-circuit OR: $t = T[e1 \text{ SC-OR } e2]$

```
t = T[ e1 ]
tjump t Lend
t = T[ e2 ]
label Lend
```

- ... how about short-circuit AND?

Translating Short-Circuit AND

- Short-circuit AND: $t = T[e1 \text{ SC-AND } e2]$

```
t = T[ e1 ]
fjump t Lend
t = T[ e2 ]
label Lend
```

Array and Field Accesses

- Array access: $t = T[v[e]]$

```
t1 = T[ e ]
t = v[t1]
```

- Field access: $t = T[e1.f]$

```
t1 = T[ e1 ]
t = t1.f
```

Nested Expressions

- In these translations, expressions may be nested;
- Translation recurses on the expression structure

- Example: $t = T[(a - b) * (c + d)]$

```

t1 = a
t2 = b
t3 = t1 - t2
t4 = c
t5 = d
t5 = t4 + t5
t = t3 * t5
  
```

$\left. \begin{array}{l} t1 = a \\ t2 = b \\ t3 = t1 - t2 \end{array} \right\} T[(a - b)]$
 $\left. \begin{array}{l} t4 = c \\ t5 = d \\ t5 = t4 + t5 \end{array} \right\} T[(c + d)]$
 $T[(a - b) * (c + d)]$

Translating Statements

- Statement sequence: $T[s1; s2; \dots; sN]$

- IR instructions of a statement sequence = concatenation of IR instructions of statements

Assignment Statements

- Variable assignment: $T[v = e]$

- Array assignment: $T[v[e1] = e2]$

Translating If-Then-Else

- $T[\text{if } (e) \text{ then } s1 \text{ else } s2]$

Translating If-Then

- $T[\text{if } (e) \text{ then } s]$

While Statements

- $T[\text{while } (e) \{ s \}]$

```
label Ltest
t1 = T[ e ]
fjump t1 Lend
T[ s ]
jump Ltest
label Lend
```

Switch Statements

- $T[\text{switch } (e) \{ \text{case } v1: s1, \dots, \text{case } vN: sN \}]$

```
t = T[ e ]
c = t != v1
tjump c L2
T[ s1 ]
jump Lend
label L2
c = t != v2
tjump c L3
T[ s2 ]
jump Lend
...
label LN
c = t != vN
tjump c Lend
T[ sN ]
label Lend
```

Call and Return Statements

- $T[\text{call } f(e1, e2, \dots, eN)]$

```
t1 = T[ e1 ]
t2 = T[ e2 ]
...
tN = T[ eN ]
call f(t1, t2, ..., tN)
```

- $T[\text{return } e]$

```
t = T[ e ]
return t
```

Nested Statements

- Same for statements as expressions: recursive translation

- Example: $T[\text{if } c \text{ then if } d \text{ then } a = b]$

```
t1 = c
fjump t1 Lend1
t2 = d
fjump t2 Lend2
t3 = b
a = t3
label Lend2
label Lend1
```

Diagram illustrating nested statements:

```

graph LR
    subgraph T_if_c_then_a_b [T[ if c then ... ] ]
        subgraph T_if_d_then_a_b [T[ if d ... ] ]
            T_a_b[T[ a = b ] ]
        end
    end
  
```

IR Lowering Efficiency
