# Discrete Kalman Filter

Estimates the state  $x$  of a discrete-time controlled process that is governed by the linear stochastic difference equation

$$x_t = A_t x_{t-1} + B_t u_t + \varepsilon_t$$

with a measurement

$$z_t = C_t x_t + \delta_t$$

# Components of a Kalman Filter

- $A_t$  Matrix ( $n \times n$ ) that describes how the state evolves from  $t$  to  $t-1$  without controls or noise.
- $B_t$  Matrix ( $n \times l$ ) that describes how the control  $u_t$  changes the state from  $t$  to  $t-1$ .
- $C_t$  Matrix ( $k \times n$ ) that describes how to map the state  $x_t$  to an observation  $z_t$ .
- $\varepsilon_t$  Random variables representing the process and measurement noise that are assumed to be independent and normally distributed with covariance  $R_t$  and  $Q_t$  respectively.
- $\delta_t$

# Multi-hypothesis Tracking

# Localization With MHT

- Belief is represented by multiple hypotheses
- Each hypothesis is tracked by a Kalman filter
- **Additional problems:**
  - **Data association:** Which observation corresponds to which hypothesis?
  - **Hypothesis management:** When to add / delete hypotheses?
- Huge body of literature on target tracking, motion correspondence etc.

# MHT: Implemented System (1)

- Hypotheses are extracted from LRF scans
- Each hypothesis has probability of being the correct one:

$$H_i = \{\hat{x}_i, \Sigma_i, P(H_i)\}$$

- Hypothesis probability is computed using Bayes' rule

$$P(H_i | s) = \frac{P(s | H_i)P(H_i)}{P(s)}$$

- Hypotheses with low probability are deleted.
- New candidates are extracted from LRF scans.

$$C_j = \{z_j, R_j\}$$
