Introduction

- Last time we saw that we can build a static type system that prevents many run-time errors.

- **Examples:** Adding ints and strings, applying a non-lambda term, ...

- We also discussed the two key properties of any type system: Preservation and Progress.

- But even in a sound type system we will prohibit some programs that would never have any run-time problems.

- **Today:** How to extend static type systems to allow polymorphism.
Consider the following function in the untyped lambda language: \( \text{lambda } x. x \)
Consider the following function in the untyped lambda language: \( \lambda x.x \)

Here, the following program is well-defined: \( \lambda x.x \ 3 \)
Motivation

- Consider the following function in the untyped lambda language: \( \text{lambda} \ x \ x \)

- Here, the following program is well-defined: \( (\text{lambda} \ x \ x \ 3) \)

- But so is the following program: \( (\text{lambda} \ x \ x \ "\text{duck}" ) \)
Motivation

- Consider the following function in the untyped lambda language: \( \text{lambda } x.x \)

- Here, the following program is well-defined: \( (\text{lambda } x.x \ 3) \)

- But so is the following program: \( (\text{lambda } x.x \ "\text{duck}" ) \)

- And the following program: \( (\text{lambda } x.x \ (\text{lambda } y.y*2)) \)
Motivation

- Consider the following function in the untyped lambda language: \( \text{lambda } x.x \)

- Here, the following program is well-defined: \( (\text{lambda } x.x \ 3) \)

- But so is the following program: \( (\text{lambda } x.x \ "duck") \)

- And the following program: \( (\text{lambda } x.x \ (\text{lambda } y.y*2)) \)

- This function can work on many (in this case, all) types!
Recall the Typed Lambda Language

\[ S \rightarrow \text{integer} \mid \text{string} \mid \text{identifier} \mid S_1 + S_2 \mid S_1 :: S_2 \mid \text{let id : } \tau = S_1 \text{ in } S_2 \mid \lambda x : \tau. S_1 \mid (S_1 \ S_2) \]

\[ \tau \rightarrow \text{Int} \mid \text{String} \mid \tau_1 \rightarrow \tau_2 \]

\[ \mid \lambda x : \tau . S_1 \]
\[ \mid (S_1 \ S_2) \]

\[ \tau \rightarrow \text{Int} \mid \text{String} \mid \tau_1 \rightarrow \tau_2 \]

- How would you write \texttt{lambda x.x} in the \textit{typed} lambda language?
Recall the Typed Lambda Language

\[ S \to \text{integer} \mid \text{string} \mid \text{identifier} \]
\[ \mid S_1 + S_2 \mid S_1 :: S_2 \]

\tau \rightarrow \text{Int} \mid \text{String} \mid \tau_1 \rightarrow \tau_2
\]

- How would you write \texttt{lambda x.x} in the typed lambda language?

- Here, types forces us to over-specialize the contexts in which this function works

- Type systems that force us to fully specify all types are known as \textit{monomorphic} type systems
This problem usually becomes especially painful when implementing data structures.
Monomorphic Type Systems

- This problem usually becomes especially painful when implementing data structures
- You end up with a vector of Ints, Strings, Foo, ...

But now we are back to run-time errors!
Fortunately, it is possible to allow polymorphism in types

We can have the cake and eat it!

This used to be mostly of academic interest, but has recently become mainstream in most languages (Java generics).
Polymorphic Types

- Fortunately, it is possible to allow polymorphism in types

- This will mean that we can write a function, such as `\( \lambda x \, x \)` that will type correctly and still have all the benefits from a sound type system

- Big Idea: Introduce type variables that can range over any type
Specifically, add the following type abstraction to our language: $\Lambda\alpha.e$
Polymorphic Types

- Specifically, add the following type abstraction to our language: $\Lambda \alpha. e$

- Think of this term as function that takes a type and substitute all occurrences of type $\alpha$ in expression $e$
Polymorphic Types

- Specifically, add the following type abstraction to our language: $\Lambda \alpha. e$

- Think of this term as a function that takes a type and substitute all occurrences of type $\alpha$ in expression $e$

- **Example**: Consider $((\Lambda \alpha. \lambda x:\alpha. x) \text{Int})$

- This evaluates to $\lambda x:\text{Int}. x$
But what is the type of an expression such as $(\Lambda \alpha. \lambda x: \alpha. x)$?
But what is the type of an expression such as \((\Lambda \alpha. \lambda x:\alpha. x)\)?

We will write the type of \(\Lambda \alpha. e\) where \(e\) evaluates to type \(\tau\) as \(\forall \alpha. \tau\).
But what is the type of an expression such as \((\Lambda \alpha. \lambda x: \alpha. x)\)?

We will write the type of \(\Lambda \alpha. e\) where \(e\) evaluates to type \(\tau\) as \(\forall \alpha. \tau\).

Intuition: This type holds for all instantiations of the type variable \(\alpha\).
But what is the type of an expression such as $(\Lambda\alpha.\lambda x:\alpha.x)$?

We will write the type of $\Lambda\alpha.e$ where $e$ evaluates to type $\tau$ as $\forall\alpha.\tau$

**Intuition:** This type holds for all instantiations of the type variable $\alpha$

**Side Note:** It is no accident that this type starts to look like a logic formula

Before we can design typing rules for our polymorphic lambda language, we have one problem.
Typing Rules Preliminaries

- Before we can design typing rules for our polymorphic lambda language, we have one problem

- Consider the expression \texttt{let x:α = ...}
Before we can design typing rules for our polymorphic lambda language, we have one problem.

Consider the expression `let x:α = ...`

Here, we don’t want type checking to succeed if `α` is not bound by a type abstraction `Λα`
Before we can design typing rules for our polymorphic lambda language, we have one problem.

Consider the expression \( \text{let } x : \alpha = \ldots \)

Here, we don’t want type checking to succeed if \( \alpha \) is not bound by a type abstraction \( \Lambda \alpha \).

Just like we use environment \( \Gamma \) to check that identifiers are used before they are defined, we need an additional environment \( \Delta \) to track that all type variables \( \alpha \) are bound.
Typing Rules Preliminaries

- But type variables don’t map to one type. We will use $\star$ to donate any well-formed type

- Signature of $\Delta$: $\alpha \mapsto \star$
Typing Rules Preliminaries

- But type variables don’t map to one type. We will use $\star$ to donate any well-formed type.

- Signature of $\Delta$: $\alpha \mapsto \star$

- We will need a judgment $\Delta \vdash \tau : \star$ asserting that type $\tau$ is well-formed.
Typing Rules Preliminaries

- But type variables don’t map to one type. We will use $\star$ to donate any well-formed type

- **Signature of $\Delta$:** $\alpha \mapsto \star$

- We will need a judgment $\Delta \vdash \tau : \star$ asserting that type $\tau$ is well-formed.

- Intuitively, type $\tau$ is well-formed if all free variables in $\tau$ are in $\Delta$
Well-formedness Rules

- Let’s give rules for this judgment:
Well-formedness Rules

Let’s give rules for this judgment:

Base case 1:

\[
\Delta \vdash Int : * \quad \Delta \vdash String : *
\]
Well-formedness Rules

- Let’s give rules for this judgment:
  - Base case 1:
    \[
    \Delta \vdash \text{Int} : \star \\
    \Delta \vdash \text{String} : \star

    \Delta \vdash \tau_1 \rightarrow \tau_2 : \star
    \]
  - Inductive Case 2:
    \[
    \Delta[\alpha \leftarrow \star] \vdash \tau : \star \\
    \Delta \vdash \forall \alpha.\tau : \star
    \]
Well-formedness Rules Cont.

    \[
    \Delta[\alpha \leftarrow \star] \vdash \tau : \star \\
    \hline
    \Delta \vdash \forall \alpha. \tau : \star
    \]
  
- All this says is that if $\Delta \vdash \tau : \star$ holds, type $\tau$ has no free variables
Typing Rules

- Let’s look at the typing rules affected by type variables:

\[ \Delta \vdash \tau_1 : \star \quad \Delta, \Gamma[x \leftarrow \tau_1] \vdash e : \tau_2 \]

\[ \Delta \vdash e : \tau_2 \rightarrow \tau_1 \]

\[ \Delta[\alpha \leftarrow \star], \Gamma \vdash e : \tau \]

\[ \Delta, \Gamma \vdash \Lambda \alpha. \, e : \forall \alpha. \tau \]
Let’s look at the typing rules affected by type variables:

- **Function definition:**

\[
\begin{align*}
\Delta &\vdash \tau_1 : \star \\
\Delta, \Gamma[x \leftarrow \tau_1] &\vdash e : \tau_2 \\
\Delta, \Gamma &\vdash \lambda x : \tau_1 \cdot e : \tau_1 \rightarrow \tau_2
\end{align*}
\]
Let’s look at the typing rules affected by type variables:

- Function definition:

\[
\begin{align*}
\Delta & \vdash \tau_1 : \star \\
\Delta, \Gamma[x \leftarrow \tau_1] & \vdash e : \tau_2 \\

- In the lambda language this makes sense since there is no point in being polymorphic with respect to monomorphic operators
It is possible (and pretty straightforward) to prove that adding polymorphism preserves progress and preservation.

Polymorphic Lambda Language Limitations

- However, sometimes we have operations that only make sense on some types, but not all types

Example: Operator + may be defined on Integers and Floats, but not vectors

The typing rules we currently gave do not allow that. A function definition will only type check if the body type checks for any possible type.

Type checking universal types for all possible instantiations is known as first-order semantics.

For this reason, real-world implementations of polymorphism do not stop here.
