1. Let $\Sigma = \{a, b\}$. Let $L_1 = \{x \in \Sigma^*: |x| < 4\}$. Let $L_2 = \{aa, aaa, aaaa\}$. List the elements in each of the following languages $L$:

(a) $L_3 = L_1 \cup L_2$
(b) $L_4 = L_1 \cap L_2$
(c) $L_5 = L_1 L_4$
(d) $L_6 = L_1 - L_2$

2. Consider the language $L = a^n b^n c^m$. Which of the following strings are in $L$?

(a) $\varepsilon$
(b) $ab$
(c) $c$
(d) $aabc$
(e) $aabcc$
(f) $abbcc$

3. It probably seems obvious to you that if you reverse a string, the character that was originally first becomes last. But the definition we've given doesn't say that; it says only that the character that was originally last becomes first. If we want to be able to use our intuition about what happens to the first character in a proof, we need to turn it into a theorem. Prove $\forall x, a$ where $x$ is a string and $a$ is a single character, $(ax)^R = x^Ra$.

4. For each of the following binary functions, state whether or not it is (i) one-to-one, (ii) onto, (iii) idempotent, (iv) commutative, and (v) associative. Also (vi) state whether or not it has an identity, and, if so, what it is. Justify your answers.

(a) $\| : S \times S \rightarrow S$, where $S$ is the set of strings of length $\geq 0$
   $\| (a, b) = a \| b$ (In other words, simply concatenation defined on strings)

(b) $\| : L \times L \rightarrow L$ where $L$ is a language over some alphabet $\Sigma$
   $\| (a, b) = \{w \in \Sigma^*: w = x \| y$ for some $x \in a$ and $y \in b\}$ In other words, the concatenation of two languages $A$ and $B$ is the set of strings that can be derived by taking a string from $A$ and then concatenating onto it a string from $B$.

5. We can define a unary function $F$ to be self-inverse iff $\forall x \in \text{Domain}(F)$ $F(F(x)) = x$. The Reverse function on strings is self-inverse, for example.

(a) Give an example of a self-inverse function on the natural numbers, on sets, and on booleans.
(b) Prove that the Reverse function on strings is self-inverse.

Solutions

1. First we observe that $L_1 = \{\varepsilon, a, b, aa, ab, ba, bb, aaa, aab, aba, abb, baa, bab, bba, bbb\}$.

(a) $L_3 = \{\varepsilon, a, b, aa, ab, ba, bb, aaa, aab, aba, abb, baa, bab, bba, bbb\}$
(b) $L_4 = \{aa, aaa\}$
(c) $L_5 = \text{every way of selecting one element from } L_1 \text{ followed by one element from } L_4$: $\{\varepsilon a, aaa, baa, aa, bba, bbaa, baaa, aab\}$ \bigcup $\{\varepsilon a, aaaa, baaa, aabaa, abaa, baaa, bbaaa, baaba, aabaa, abaaa\}$
(d) $L_6 = \text{every string that is in } L_1 \text{ but not in } L_2$: $\{\varepsilon, a, b, ab, ba, bb, aab, aba, abb, baa, bab, bba, bbb\}$. 

Homework 2
Strings and Languages
1
2. (a) Yes.  \( n = 0 \) and \( m = 0 \).
(b) Yes.  \( n = 1 \) and \( m = 0 \).
(c) Yes.  \( n = 0 \) and \( m = 1 \).
(d) No.  There must be equal numbers of a's and b's.
(e) Yes.  \( n = 2 \) and \( m = 2 \).
(f) No.  There must be equal numbers of a's and b's.

3. Prove: \( \forall x, a \) where \( x \) is a string and \( a \) is a single character, \((ax)^R = x^Ra \). We'll use induction on the length of \( x \). If \(|x| = 0 \) (i.e. \( x = \varepsilon \)), then \((ae)^R = a = \varepsilon^Ra \). Next we show that if this is true for all strings of length \( n \), then it is true for all strings of length \( n + 1 \). Consider any string \( x \) of length \( n + 1 \). Since \(|x| > 0\), we can rewrite \( x \) as \( yb \) for some single character \( b \).

\[
(ax)^R = (ayb)^R \quad \text{Rewrite of } x \text{ as } yb \\
= b(ay)^R \quad \text{Definition of reversal} \\
= b(y^Ra) \quad \text{Induction hypothesis (since } |x| = n + 1, |y| = n) \\
= (b^R y^R)a \quad \text{Associativity of concatenation} \\
= x^Ra \quad \text{Definition of reversal: If } x = yb \text{ then } x^R = by^R
\]

4. (a) (i) \( \| \) is not one-to-one. For example, \( \| \{(ab, c)\} = \| \{(a, bc)\} = abc \).
(ii) \( \| \) is onto. Proof: \( \forall s \in S, \| \{(s, \varepsilon)\} = s \), so every element of \( s \) can be generated.
(iii) \( \| \) is not idempotent. \( \| \{(a, a)\} \neq a \).
(iv) \( \| \) is not commutative. \( \| \{(ab, cd)\} \neq \| \{(cd, ab)\} \).
(v) \( \| \) is associative.
(vi) \( \| \) has \( \varepsilon \) as both a left and right identity.

(b) (i) \( \| \) is not one to one. For example, Let \( \Sigma = \{a, b, c\} \). \( \| \{(a, \{bc\})\} = \{abc\} = \| \{(ab, \{c\})\} \).
(ii) \( \| \) is onto. Proof: \( \forall L \subseteq \Sigma^*, \| \{(L, \{\varepsilon\})\} = L \), so every element of \( s \) can be generated. Notice that this proof is very similar to the one we used to show that concatenation of strings is onto. Both proofs rely on the fact that \( \varepsilon \) is an identity for concatenation of strings. Given the way in which we defined concatenation of languages as the concatenation of strings drawn from the two languages, \( \{\varepsilon\} \) is an identity for concatenation of languages and thus it enables us to prove that all languages can be derived from the concatenation operation.
(iii) \( \| \) is not idempotent. \( \| \{\{a\}, \{a\}\} = \{aa\} \).
(iv) \( \| \) is not commutative. \( \| \{\{a\}, \{b\}\} = \{ab\} \). But \( \| \{\{b\}, \{a\}\} = \{ba\} \).
(v) \( \| \) is associative.
(vi) \( \| \) has \( \{\varepsilon\} \) as both a left and right identity.

5. (a) Integers: \( F(x) = -x \) is self-inverse. Sets: Complement is self-inverse. Booleans: Not is self-inverse.
(b) We'll prove this by induction on the length of the string.
Base case: If \(|x| = 0 \) or \( 1 \), then \( x^R = x \). So \( (x^R)^R = x^R = x \).
Show that if this is true for all strings of length \( n \), then it is true for all strings of length \( n + 1 \). Any string \( s \) of length \( n + 1 \) can be rewritten as \( xa \) for some single character \( a \). So now we have:

\[
s^R = a x^R \quad \text{definition of string reversal} \\
(s^R)^R = (a x^R)^R \quad \text{substituting } x^R \text{ for } s^R \\
= (x^R)^Ra \quad \text{by the theorem we proved above in (3)} \\
= xa \quad \text{induction hypothesis} \\
= s \quad \text{since } xa \text{ was just a way of rewriting } s
\]
