"Given enough eyeballs, all bugs are shallow (e.g., given a large enough beta-tester and co-developer base, almost every problem will be characterized quickly and the fix obvious to someone)."

-Linus's Law, by Eric Raymond
A deceptive problem...

- Write a method `printNumbers` that prints each number from 1 to a given maximum, separated by commas.

For example, the call:

```
printNumbers(5)
```

should print:

```
1, 2, 3, 4, 5
```
Flawed solutions

- public static void printNumbers(int max) {
  for (int i = 1; i <= max; i++) {
    System.out.print(i + ",");
  }
  System.out.println(); // to end the line of output
}

  Output from printNumbers(5):  1, 2, 3, 4, 5,

- public static void printNumbers(int max) {
  for (int i = 1; i <= max; i++) {
    System.out.print(",", " + i);
  }
  System.out.println(); // to end the line of output
}

  Output from printNumbers(5): , 1, 2, 3, 4, 5
Fence post analogy

- We print $n$ numbers but need only $n - 1$ commas.
- Similar to building a fence with wires separated by posts:
  - If we use a flawed algorithm that repeatedly places a post + wire, the last post will have an extra dangling wire.

```plaintext
for (length of fence) {
    place a post.
    place some wire.
}
```
Fencepost loop

- Add a statement outside the loop to place the initial "post."
  - Also called a fencepost loop or a "loop-and-a-half" solution.

*place a post.*
for (length of fence - 1) {
  *place some wire.*
  *place a post.*
}

- Diagram of fence with posts and wire.
Fencepost method solution

```java
public static void printNumbers(int max) {
    System.out.print(1);
    for (int i = 2; i <= max; i++) {
        System.out.print(",", " + i);
    }
    System.out.println(); // to end the line
}
```

- Alternate solution: Either first or last "post" can be taken out:

```java
public static void printNumbers(int max) {
    for (int i = 1; i <= max - 1; i++) {
        System.out.print(i + "", ");
    }
    System.out.println(max); // to end the line
}
```
Modify your method `printNumbers` into a new method `printPrimes` that prints all prime numbers up to a max.

- Example: `printPrimes(50)` prints 2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47

- If the maximum is less than 2, print no output.

To help you, write a method `countFactors` which returns the number of factors of a given integer.

- `countFactors(20)` returns 6 due to factors 1, 2, 4, 5, 10, 20.
// Prints all prime numbers up to the given max.
public static void printPrimes(int max) {
    if (max >= 2) {
        System.out.print("2");
        for (int i = 3; i <= max; i++) {
            if (countFactors(i) == 2) {
                System.out.print("", " + i);
            }
        }
        System.out.println();
    }
}

// Returns how many factors the given number has.
public static int countFactors(int number) {
    int count = 0;
    for (int i = 1; i <= number; i++) {
        if (number % i == 0) {
            count++;
        }
    }
    return count;
}
while loops

reading: 5.1
Categories of loops

- **definite loop**: Executes a known number of times.
  - The for loops we have seen are definite loops.
    - Print "hello" 10 times.
    - Find all the prime numbers up to an integer $n$.
    - Print each odd number between 5 and 127.

- **indefinite loop**: One where the number of times its body repeats is not known in advance.
  - Prompt the user until they type a non-negative number.
  - Print random numbers until a prime number is printed.
  - Repeat until the user has typed "q" to quit.
The **while** loop

**while loop**: Repeatedly executes its body as long as a logical test is true.

```
while (<test>) {
    <statement(s)>;
}
```

**Example:**

```java
int num = 1; // initialization
while (num <= 200) { // test
    System.out.print(num + " ");
    num = num * 2; // update
}
```

// output:  1  2  4  8  16  32  64  128
Example **while** loop

// finds the first factor of 91, other than 1
int n = 91;
int factor = 2;
while (n % factor != 0) {
    factor++;
}
System.out.println("First factor is " + factor);

// output: First factor is 7

- *while* is better than *for* because we don't know how many times we will need to increment to find the factor.
What is output by the following code?

```java
int sum = 0;
int limit = 60;
int val = 1;
while(val < limit) {
    sum++;
}
System.out.println(sum);
```

A. 0  B. 60  C. 61

D. No output due to syntax error

E. No output due to some other reason
Sentinel values

- **sentinel**: A value that signals the end of user input.
  - **sentinel loop**: Repeats until a sentinel value is seen.

Example: Write a program that prompts the user for text until the user types nothing, then output the total number of characters typed.
  - (In this case, the *empty* string is the sentinel value.)

```
Type a line (or nothing to exit): hello
Type a line (or nothing to exit): this is a line
Type a line (or nothing to exit):
You typed a total of 19 characters.
```
Scanner console = new Scanner(System.in);
int sum = 0;
String response = "dummy"; // "dummy" value, anything but ""
while (!response.equals("")) {
    System.out.print("Type a line (or nothing to exit): ");
    response = console.nextLine();
    sum += response.length();
}
System.out.println("You typed a total of " + sum + " characters.");
Changing the sentinel value

Modify your program to use "quit" as the sentinel value.

– Example log of execution:

Type a line (or "quit" to exit): hello
Type a line (or "quit" to exit): this is a line
Type a line (or "quit" to exit): quit
You typed a total of 19 characters.
Changing the sentinel's value to "quit" does not work!

Scanner console = new Scanner(System.in);
int sum = 0;
String response = "dummy"; // "dummy" value, anything but "quit"

while (!response.equals("quit")) {
    System.out.print("Type a line (or \"quit\" to exit): ");
    response = console.nextLine();
    sum += response.length();
}
System.out.println("You typed a total of " + sum + " characters.");

This solution produces the wrong output. Why?
You typed a total of 23 characters.
The problem with the code

- The code uses a pattern like this:
  
  ```
  sum = 0.
  while (input is not the sentinel) {
    prompt for input; read input.
    add input length to the sum.
  }
  ```
problem with code

- On the last pass, the sentinel’s length (4) is added to the sum:

  prompt for input; read input ("quit").
  add input length (4) to the sum.

- This is a fencepost problem.
  - Must read $N$ lines, but only sum the lengths of the first $N-1$. 
A fencepost solution

\[ \text{sum} = 0. \]

\textit{prompt for input; read input.} \quad \textit{// place a "post"

\textbf{while} (input is not the sentinel) \{ 
  \textit{add input length to the sum.} \quad \textit{// place a "wire"
  \textit{prompt for input; read input.} \quad \textit{// place a "post"
\}

\textbf{ Sentinel loops often utilize a fencepost "loop-and-a-half" style solution by pulling some code out of the loop.}
Correct code

Scanner console = new Scanner(System.in);
int sum = 0;

// pull one prompt/read ("post") out of the loop
System.out.print("Type a line (or \"quit\" to exit): ");
String response = console.nextLine();

while (!response.equals("quit")) {
    sum += response.length();  // moved to top of loop
    System.out.print("Type a line (or \"quit\" to exit): ");
    response = console.nextLine();
}

System.out.println("You typed a total of " + sum + " characters.");
public static final String SENTINEL = "quit";
...

Scanner console = new Scanner(System.in);
int sum = 0;

// pull one prompt/read ("post") out of the loop
System.out.print("Type a line (or \"" + SENTINEL + "\" to exit): ");
String response = console.nextLine();

while (!response.equals(SENTINEL)) {
    sum += response.length();  // moved to top of loop
    System.out.print("Type a line (or \"" + SENTINEL + "\" to exit): ");
    response = console.nextLine();
}

System.out.println("You typed a total of " + sum + " characters.");
examples

• write a method to improve checking if a number is prime or not
  – when can we stop?

• Write a program that flips a coin until there is a run of 10 flips of the same side in a row
  – how many flips were there before 10 in a row?
  – repeat the experiment 1000 times, what is the average number of flips
