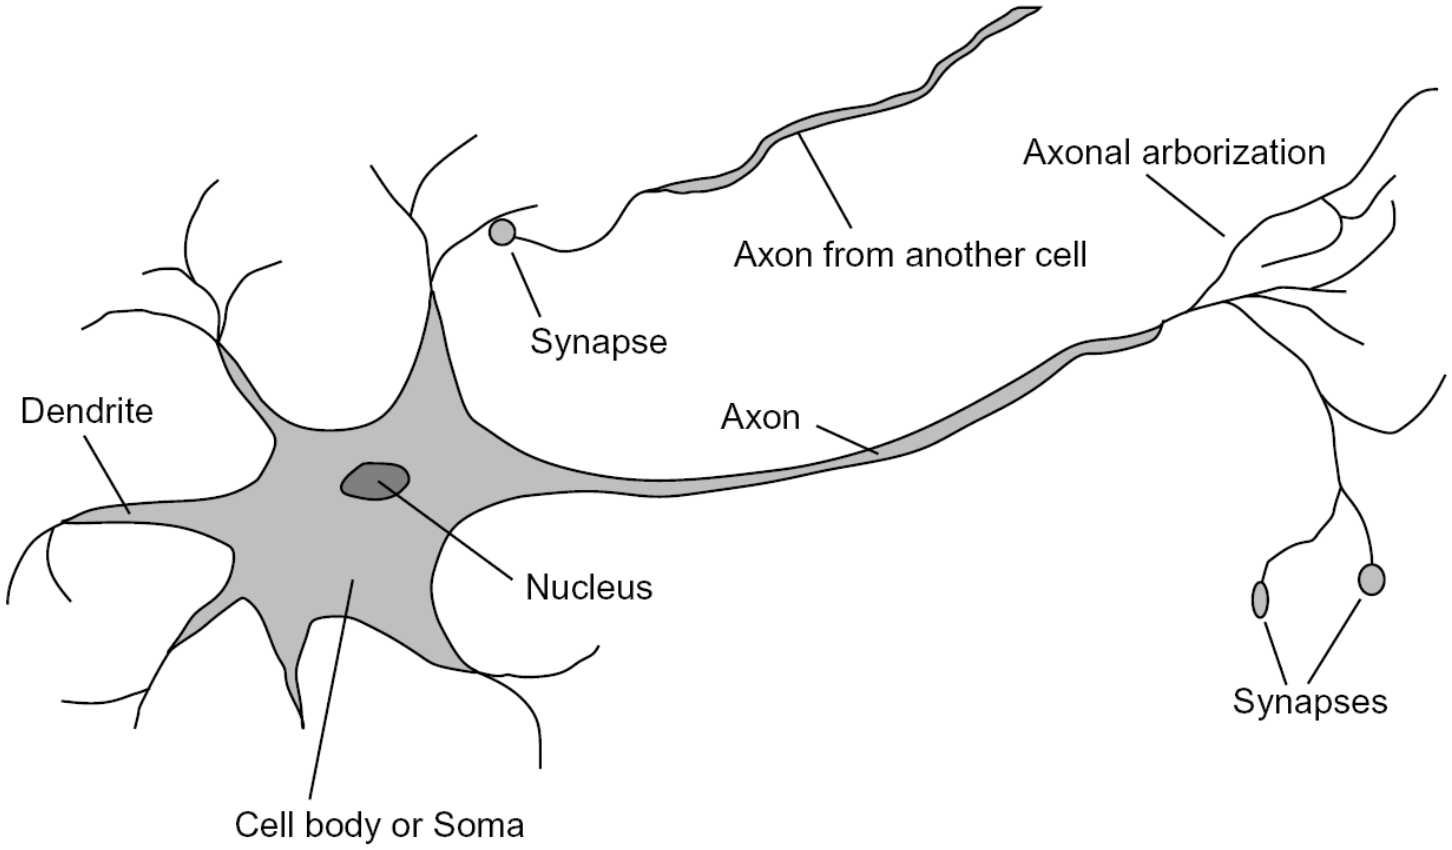
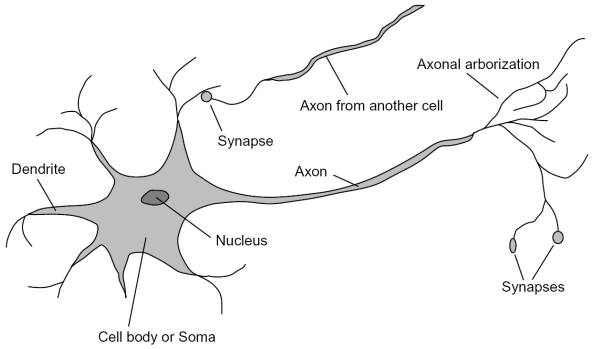
Some (Simplified) Biology

- Very loose inspiration: human neurons



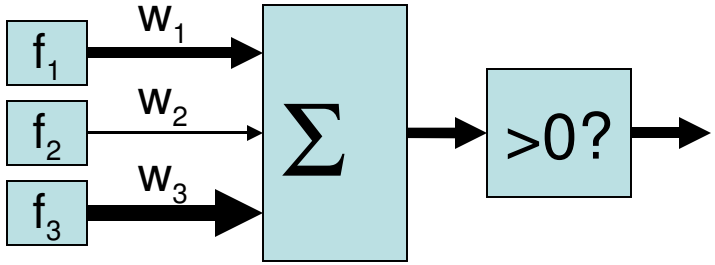
Linear Classifiers

- Inputs are feature values
- Each feature has a weight
- Sum is the activation



$$\text{activation}_w(x) = \sum_i w_i \cdot f_i(x) = w \cdot f(x)$$

- If the activation is:
  - Positive, output +1
  - Negative, output -1



Example: Spam

- Imagine 4 features (spam is "positive" class):
  - free (number of occurrences of "free")
  - money (occurrences of "money")
  - BIAS (intercept, always has value 1)

$$w \cdot f(x)$$

$$\sum_i w_i \cdot f_i(x)$$

x

"free money"

$f(x)$

BIAS	1
free	1
money	1
...	

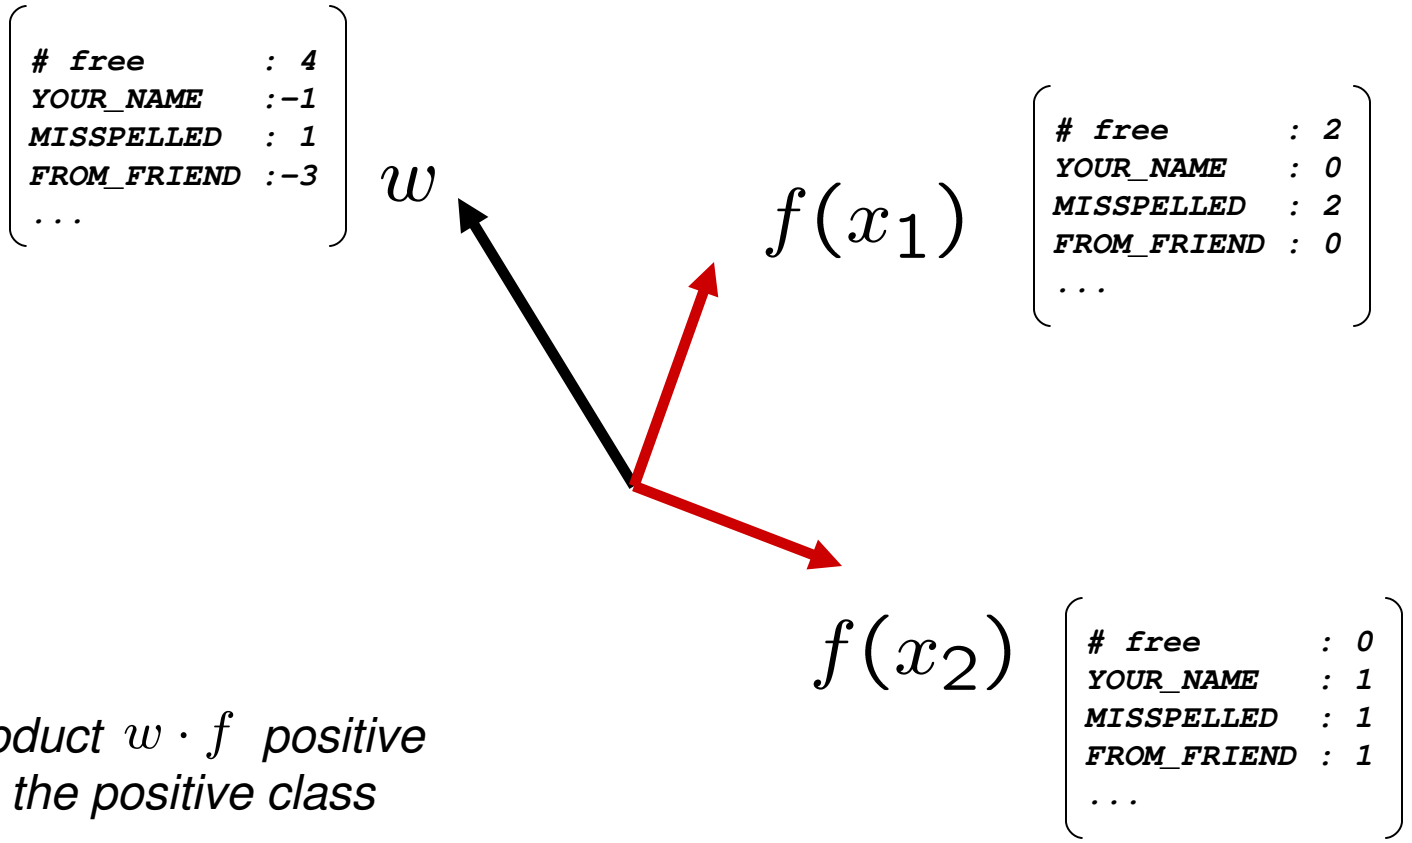
w

BIAS	-3
free	4
money	2
...	

$$(1)(-3) + (1)(4) + (1)(2) + \ldots = 3$$

Classification: Weights

- Binary case: compare features to a weight vector
- Learning: figure out the weight vector from examples



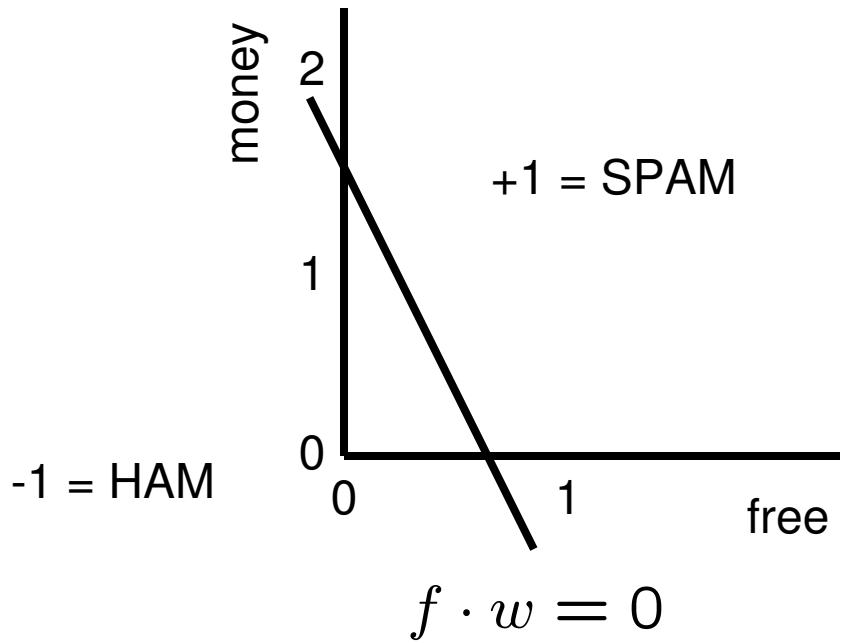
Dot product $w \cdot f$ positive means the positive class

Binary Decision Rule

- In the space of feature vectors
  - Examples are points
  - Any weight vector is a hyperplane
  - One side corresponds to Y=+1
  - Other corresponds to Y=-1

w

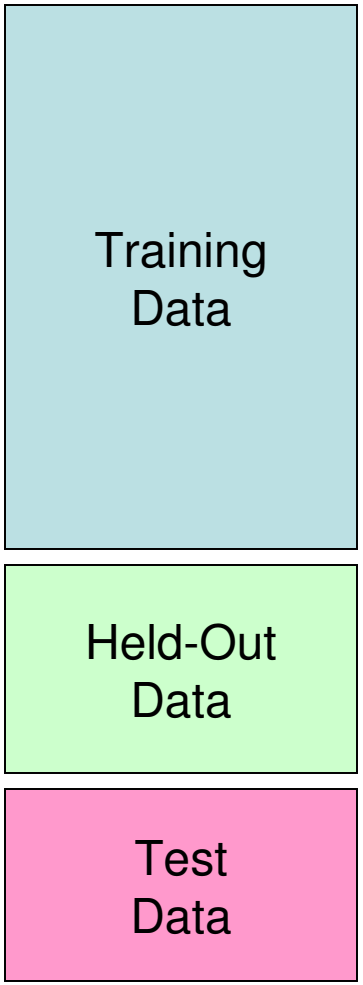
```
BIAS   : -3
free   :  4
money  :  2
...
```



Mistake-Driven Classification

- For Naïve Bayes:
  - Parameters from data statistics
  - Parameters: causal interpretation
  - Training: one pass through the data

- For the perceptron:
  - Parameters from reactions to mistakes
  - Prameters: discriminative interpretation
  - Training: go through the data until held-out accuracy maxes out



Learning: Binary Perceptron

- Start with weights = 0
- For each training instance:
  - Classify with current weights

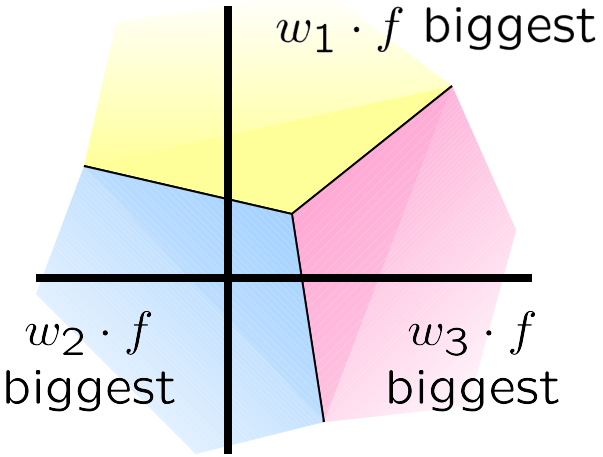
$$y = \begin{cases} +1 & \text{if } w \cdot f(x) \geq 0 \\ -1 & \text{if } w \cdot f(x) < 0 \end{cases}$$

  - If correct (i.e., y=y*), no change!
  - If wrong: adjust the weight vector by adding or subtracting the feature vector. Subtract if y* is -1.

$$w = w + y^* \cdot f$$

Multiclass Decision Rule

- If we have more than two classes:
  - Have a weight vector for each class: w_y
  - Calculate an activation for each class



$$\text{activation}_w(x, y) = w_y \cdot f(x)$$

  - Highest activation wins

$$y = \arg\max_y \ (\text{activation}_w(x, y))$$

Multiclass Decision Rule

- If we have multiple classes:
  - A weight vector for each class:

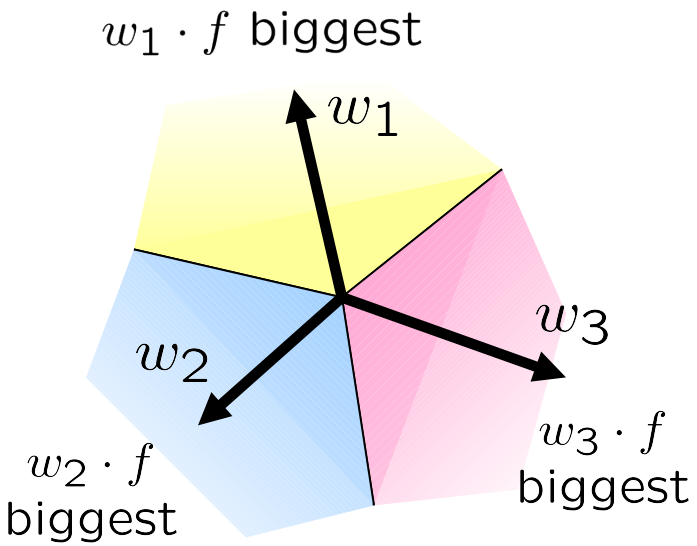
$$w_y$$

  - Score (activation) of a class y:

$$w_y \cdot f(x)$$

  - Prediction highest score wins

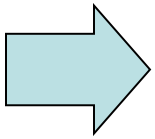
$$y = \arg\max_y \ w_y \cdot f(x)$$



Binary = multiclass where the negative class has weight zero

Example

"win the vote"



```
BIAS   :  1
win    :  1
game   :  0
vote   :  1
the    :  1
...
```

w_{SPORTS}

```
BIAS   : -2
win    :  4
game   :  4
vote   :  0
the    :  0
...
```

$w_{POLITICS}$

```
BIAS   :  1
win    :  2
game   :  0
vote   :  4
the    :  0
...
```

w_{TECH}

```
BIAS   :  2
win    :  0
game   :  2
vote   :  0
the    :  0
...
```

Learning: Multiclass Perceptron

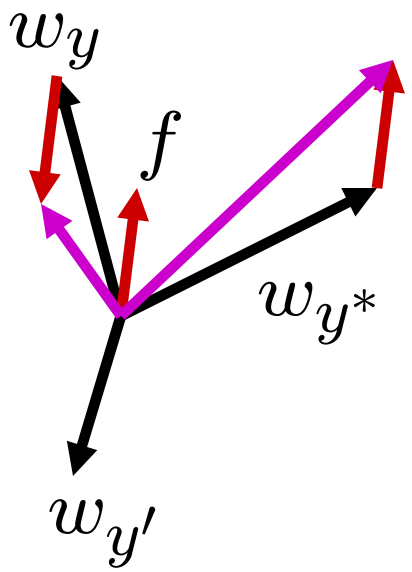
- Start with all weights = 0
- Pick up training examples one by one
- Predict with current weights

$$y = \arg\max_y \; w_y \cdot f(x)$$

- If correct, no change!
- If wrong: lower score of wrong answer, raise score of right answer

$$w_y = w_y - f(x)$$

$$w_{y^*} = w_{y^*} + f(x)$$



Example: Multiclass Perceptron

"win the vote"

"win the election"

"win the game"

w_{SPORTS}

```
BIAS  : 1
win   : 0
game  : 0
vote  : 0
the   : 0
...
```

$w_{POLITICS}$

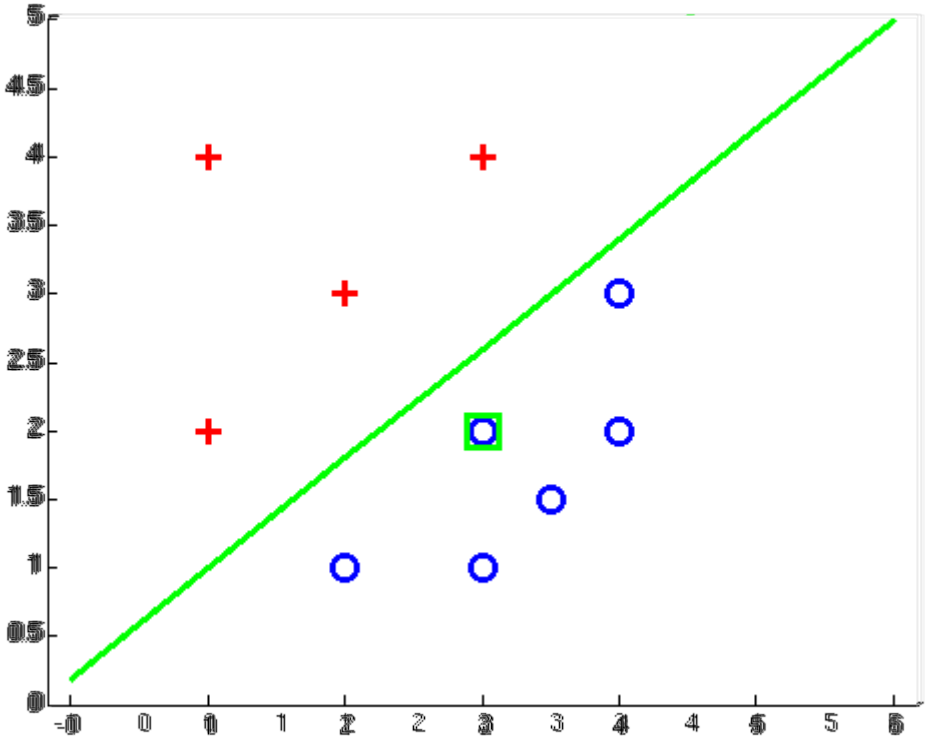
```
BIAS  : 0
win   : 0
game  : 0
vote  : 0
the   : 0
...
```

w_{TECH}

```
BIAS  : 0
win   : 0
game  : 0
vote  : 0
the   : 0
...
```

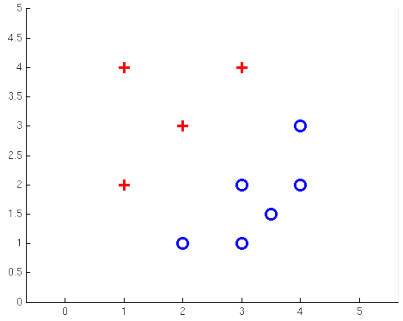
Examples: Perceptron

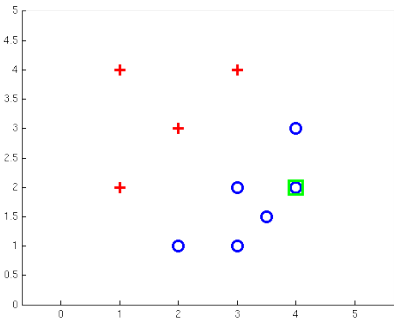
- Separable Case

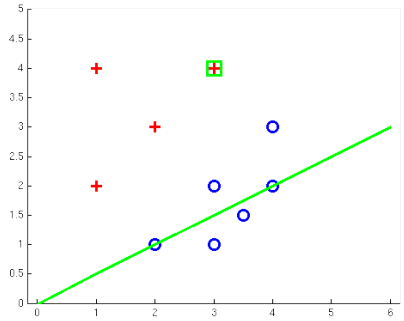


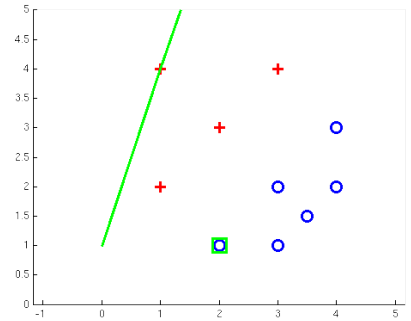
Examples: Perceptron

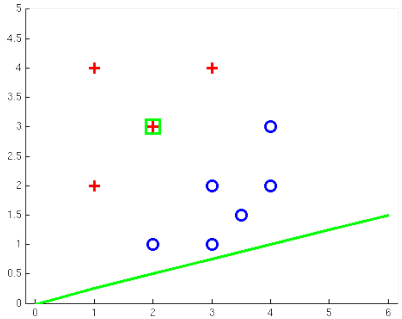
- Separable Case

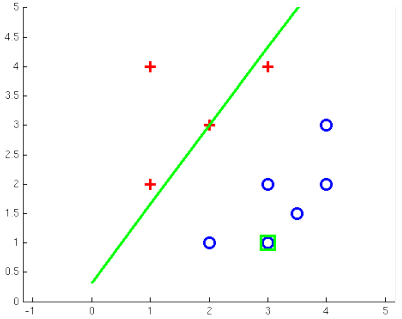


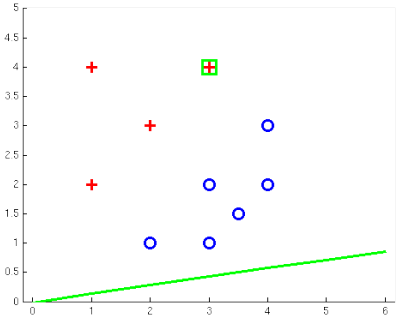


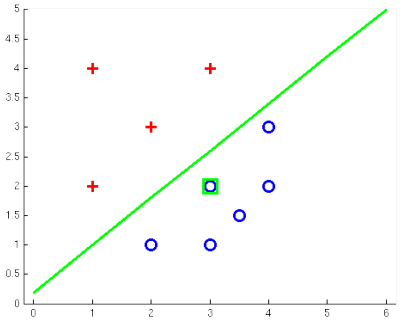










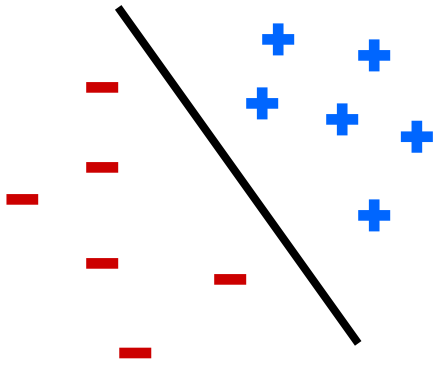


Properties of Perceptrons

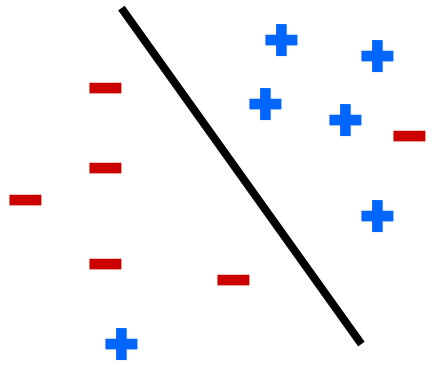
- Separability: some parameters get the training set perfectly correct
- Convergence: if the training is separable, perceptron will eventually converge (binary case)
- Mistake Bound: the maximum number of mistakes (binary case) related to the *margin* or degree of separability

$$\text{mistakes} < \frac{k}{\delta^2}$$

Separable

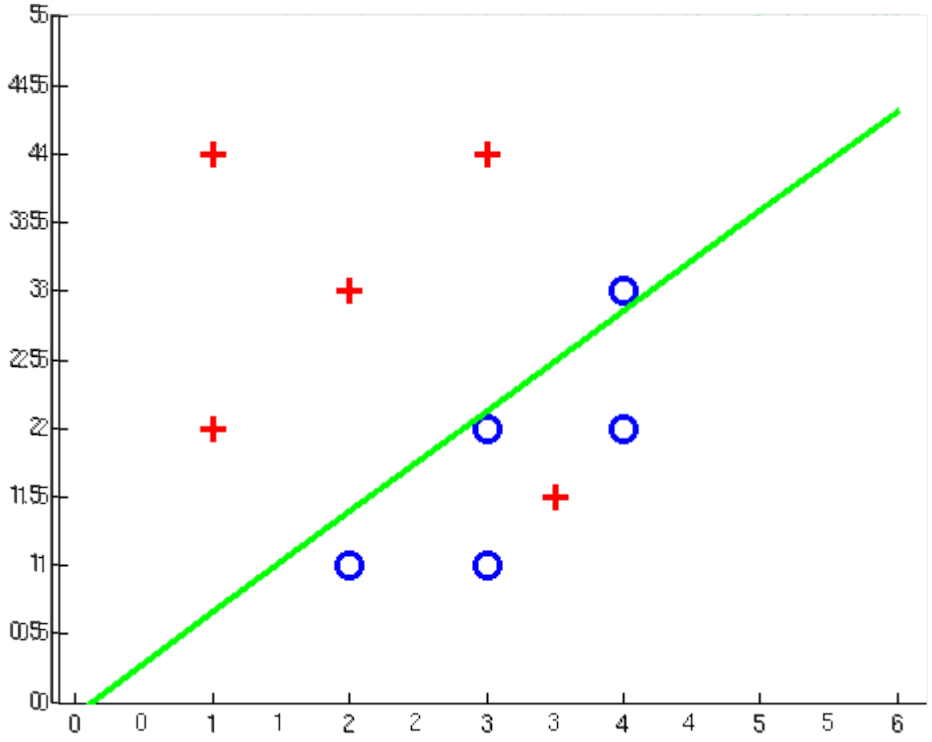


Non-Separable



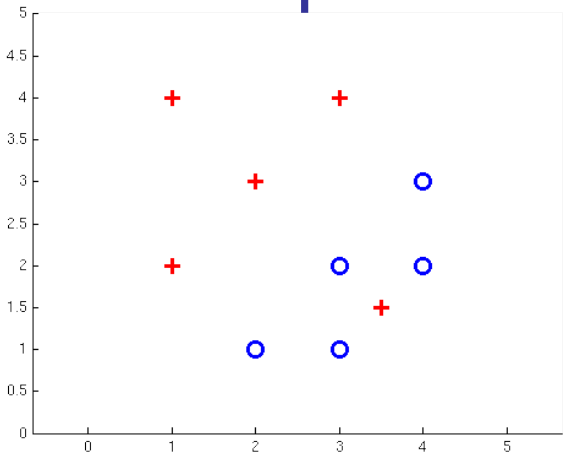
Examples: Perceptron

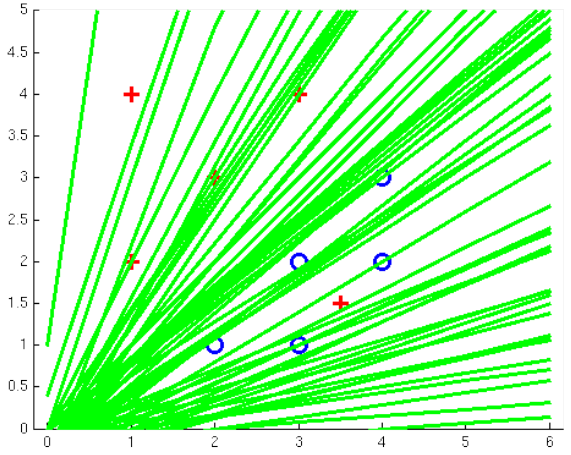
- Non-Separable Case

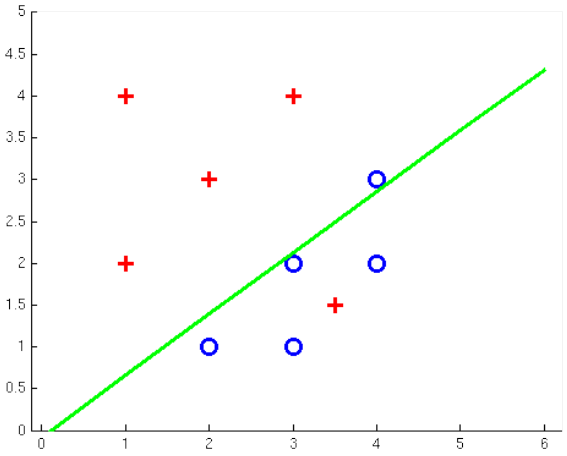


Examples: Perceptron

- Non-Separable Case

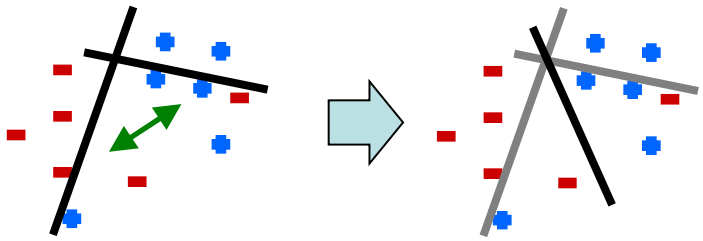




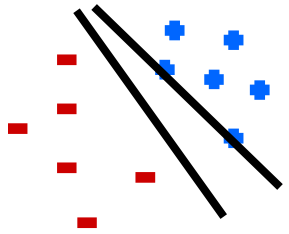


Problems with the Perceptron

- Noise: if the data isn't separable, weights might thrash
  - Averaging weight vectors over time can help (averaged perceptron)



- Mediocre generalization: finds a "barely" separating solution



- Overtraining: test / held-out accuracy usually rises, then falls
  - Overtraining is a kind of overfitting
