Nevertheless, if one of these events occurs, the corresponding path must be forced to reset by software before being reconfigured. For more information about events servicing, see [Section 23.6.5.1.2, McPDM Events Servicing](#).

Moreover, a FIFO-uplink-empty or FIFO-downlink-full event occurs only when all the channels of the corresponding path have been disabled during normal operation.

**NOTE:** Channels must not be enabled or disabled during normal operation.

Channels can be enabled or disabled when the corresponding path is forced to reset. For more information about McPDM software reset, see [Section 23.6.4.3, McPDM Software Reset](#).

## 23.6.5 McPDM Programming Guide

### 23.6.5.1 McPDM Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 23.6.5.1.1 Global Initialization

##### 23.6.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules in the device when the McPDM module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the environment and the integration of the McPDM. For more information, see [Section 23.6.2, McPDM Environment](#), and [Section 23.6.3, McPDM Integration](#).

[Table 23-474](#) describes the global initialization of surrounding modules.

**Table 23-474. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM module	The McPDM interface clock must be enabled and the functional clock must not be gated.
Control module	The McPDM-specific pad muxing must be configured in the device control module.
(Optional) Cortex-A9 MPU INTC (or DSP INTC)	The Cortex-A9 MPU (or DSP) INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU (or DSP) subsystem when interrupt requests are generated by the McPDM module.
(Optional) sDMA (or eDMA or aDMA)	The sDMA (or eDMA or aDMA) controller must be configured to account for the DMA requests generated by the McPDM module in the case of autonomous data transfers from/to memory.
(Optional) Interconnect	For more information about the interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .
External audio chip	Initialize the external audio chip according to the specific needs.
I <sup>2</sup> C controller	For more information about the I <sup>2</sup> C initialization, see <a href="#">Section 23.1, Multimaster High-Speed I<sup>2</sup>C Controller</a> .

### 23.6.5.1.1.2 McPDM Global Initialization

#### 23.6.5.1.1.2.1 Main Sequence – McPDM Global Initialization

This procedure initializes the McPDM after a power-on reset (POR) or software reset. [Figure 23-174](#) shows a flow chart for the global initialization of the McPDM module.

**Figure 23-174. McPDM Global Initialization Flow Chart**

mcpdm-013

The McPDM software reset is executed by setting the `MCPDM_SYSCONFIG[0] SOFTRESET` bit to 0x1. To detect the reset done event, user software must check this bit until it is cleared to 0x0 by the hardware.

Configuration of the offset cancellation feature is optional. The use of that feature depends on the characteristics of the external audio chip attached to the McPDM interface. If the external chip adds some DC offset on its output, then the offset cancellation feature of the McPDM must be used.

[Table 23-475](#) describes the steps of the downlink path global initialization.

**Table 23-475. McPDM Downlink Path Global Initialization**

Procedure	Step	Access Type	Register/Bit Field/Programming Model	Value
Configure the offset cancellation feature. Only downlink path 1 and downlink path 2 can use the offset cancellation feature.	1. Read the offset value for the audio downlink path 1 from the external audio companion chip through the I <sup>2</sup> C interface.	R	Offset register 1 in the external audio companion chip	OFFSET1
	2. Configure the offset of the audio downlink path 1.	W	<a href="#">MCPDM_DN_OFFSET</a> [5:1] DN_OFST_RX1	OFFSET1
	3. Enable the offset cancellation feature for the audio downlink path 1.	W	<a href="#">MCPDM_DN_OFFSET</a> [0] DN_OFST_RX1_EN	0x1
	4. Read the offset value for the audio downlink path 2 from the external audio companion chip through the I <sup>2</sup> C interface.	R	Offset register 2 in the external audio companion chip	OFFSET2
	5. Configure the offset of the audio downlink path 2.	W	<a href="#">MCPDM_DN_OFFSET</a> [13:9] DN_OFST_RX2	OFFSET2
	6. Enable the offset cancellation feature for the audio downlink path 2.	W	<a href="#">MCPDM_DN_OFFSET</a> [8] DN_OFST_RX2_EN	0x1
Configure the audio downlink path.	1. Enable the interrupt request generation for the downlink path.	W	a. <a href="#">MCPDM_IRQENABLE_SET</a> [3] DN_IRQ_FULL_MASK b. <a href="#">MCPDM_IRQENABLE_SET</a> [2] DN_IRQ_ALMST_EMPTY_MASK c. <a href="#">MCPDM_IRQENABLE_SET</a> [1] DN_IRQ_EMPTY_MASK d. <a href="#">MCPDM_IRQENABLE_SET</a> [0] DN_IRQ_MASK	When downlink DMA request not used: 0xF When downlink DMA request used: 0xE
	2. Configure the FIFO downlink threshold.	W	<a href="#">MCPDM_FIFO_CTRL_DN</a> [3:0] DN_TRESH	FIFO downlink threshold
	3. Enable the DMA request generation for the downlink path (optional: only if DMA request generation for the downlink path is required).	W	<a href="#">MCPDM_DMAENABLE_SET</a> [0] DMA_DN_ENABLE	0x1
	4. Enable the downlink channels.	W	<a href="#">MCPDM_CTRL</a>	See <a href="#">Table 23-471</a> .

[Table 23-476](#) describes the steps of the uplink path global initialization.

**Table 23-476. McPDM Uplink Path Global Initialization**

Step	Access Type	Register/Bit Field/Programming Model	Value
1. Enable the interrupt request generation for the uplink path.	W	a. <a href="#">MCPDM_IRQENABLE_SET</a> [11] UP_IRQ_FULL_MASK b. <a href="#">MCPDM_IRQENABLE_SET</a> [10] UP_IRQ_ALMST_FULL_MASK c. <a href="#">MCPDM_IRQENABLE_SET</a> [9] UP_IRQ_EMPTY_MASK d. <a href="#">MCPDM_IRQENABLE_SET</a> [8] UP_IRQ_MASK	When uplink DMA request not used: 0xF When uplink DMA request used: 0xE
2. Configure the FIFO uplink threshold.	W	<a href="#">MCPDM_FIFO_CTRL_UP</a> [3:0] UP_TRESH	FIFO uplink threshold
3. Enable the DMA request generation for the uplink path (optional: only if DMA request generation for the uplink path is required).	W	<a href="#">MCPDM_DMAENABLE_SET</a> [1] DMA_UP_ENABLE	0x1

**Table 23-476. McPDM Uplink Path Global Initialization (continued)**

Step	Access Type	Register/Bit Field/Programming Model	Value
4. Configure the FIFO uplink sampling frequency.	W	MCPDM_CTRL[13] DIV_SEL	0x-
5. Enable the uplink channels.	W	MCPDM_CTRL	See Table 23-471.

### 23.6.5.1.2 McPDM Events Servicing

#### 23.6.5.1.2.1 Downlink Path Event Servicing

Table 23-477 to Table 23-480 describe the downlink path event servicing.

When the four downlink interrupts are enabled and then the downlink channel(s) is enabled, the FIFO-downlink-write request (MCPDM\_IRQSTATUS = 0x1), instead of the FIFO-downlink-empty request (MCPDM\_IRQSTATUS = 0x2), is generated. The first audio data to be sent is written from the interrupt handler. The McPDM module can work in two ways:

- Enable the desired downlink channels, and then write in the downlink FIFO the audio data that is going to be sent.
- Write the audio data in the downlink FIFO, and then enable the desired downlink channels to send this audio data.

In either way, the FIFO-downlink-write request is generated.

**Table 23-477. FIFO-Downlink-Full Event Servicing**

Step	Access Type	Register/Bit Field/Programming Model	Value
<b>TEST TA:</b> Is FIFO downlink full?	R	MCPDM_IRQSTATUS[3] DN_IRQ_FULL	
<b>IF: TRUE</b>			0x1
Acknowledge event.	W	MCPDM_IRQSTATUS[3] DN_IRQ_FULL	0x1
Downlink path reset	W	MCPDM_CTRL[12] SW_DN_RST	0x1
Downlink path global initialization		See Table 23-475.

## 23.7 Digital Microphone Module

This section describes the digital microphone (DMIC) module.

### 23.7.1 DMIC Overview

The digital microphone (DMIC) module consists of an audio module dedicated to a mobile telephone terminal. The DMIC allows the support of up to six digital microphones. It provides an interface between the audio backend (ABE) module and microphones connected through the 6-wire DMIC serial interface.

The DMIC supports six paths. Because each path is composed of two digital microphone channels, the DMIC can be used with three stereo or six mono microphones. Each path is enabled or disabled independently.

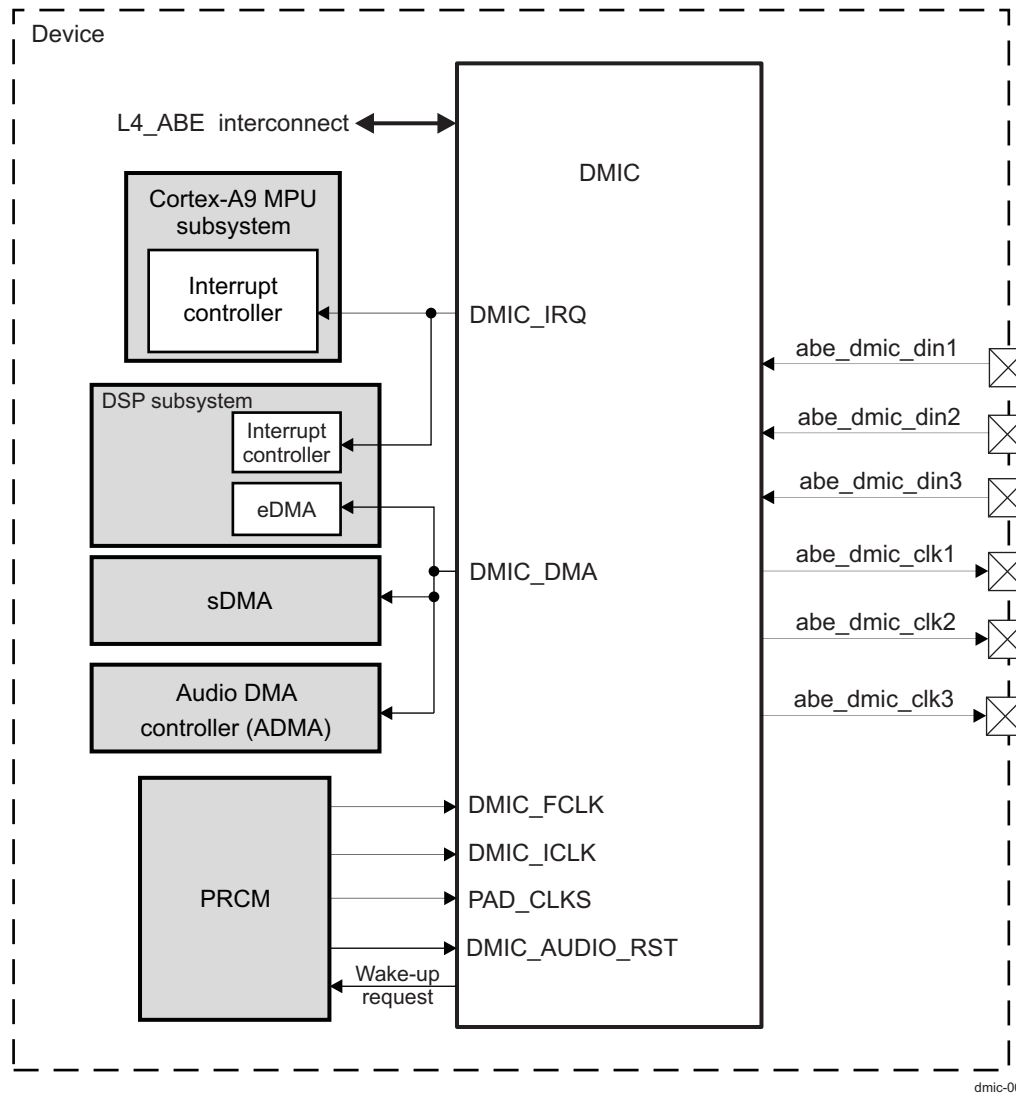

The DMIC generates a pulse-density modulated (PDM) stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC (oversampling clock).

Each microphone is directly connected to a filter decimator to extract the audio samples at the desired accuracy and sample rate. Data are stored in the first in first out (FIFO), which is controlled by interrupt request (IRQ) and direct memory access (DMA) request.

The DMIC pads are supplied with 1.8 V. These pads assure the transition to the host supply.

[Figure 23-175](#) shows the DMIC in the device.

Figure 23-175. DMIC

The main features of the DMIC are:

- Six external pin connections (three data lines and three clock lines)
- Using the three clock lines, the DMIC delivers three clock signals (same frequency, individually gateable) for all digital microphones.
- Using the three data lines, the DMIC receives audio data from external microphones.
- Supports stereo (up to three) and mono (up to six) digital microphones
- Each line can support two microphones working in clock phase opposition.
- Selectable functional clock source
- Programmable output clock frequency ( $32 \times FS$ ,  $50 \times FS$ ,  $64 \times FS$ , or  $80 \times FS$ , where  $FS = 48 \text{ kHz}$ )
- Programmable data sampling sensibility (rising or falling edge)
- One RX FIFO (16 words of 144 bits)
- Supports idle request/acknowledge power, reset, and clock management (PRCM) module protocol
- Interconnect sample format: 32 bits (only 24 are significant)
- One IRQ to the microprocessor unit (Cortex™-A9 microprocessor unit [MPU]) and digital signal processor (DSP) subsystems
- One DMA request capability on programmable FIFO threshold

### 23.7.2 DMIC Environment

This section describes the DMIC application fields from an environment point of view (that is, external connections). It presents the DMIC connectivity options, lists possible interfaces, and details the protocol and data format used in each case.

#### 23.7.2.1 DMIC Interface With External MIC

##### 23.7.2.1.1 DMIC Interface Overview

The DMIC interface is a 6-wire interface. The DMIC module can support up to three external stereo and six mono digital microphones. A DMIC is an external module that can deliver data. A clock is sent from the host to the microphone.

Figure 23-176 and Figure 23-177 show two cases of use of the DMIC, but all configurations are possible with stereo and mono digital microphones. The output of the DMIC is in 32-bit format.

Figure 23-176 shows the DMIC used with three stereo DMICs.

Figure 23-176. DMIC With Three Stereo DMICs

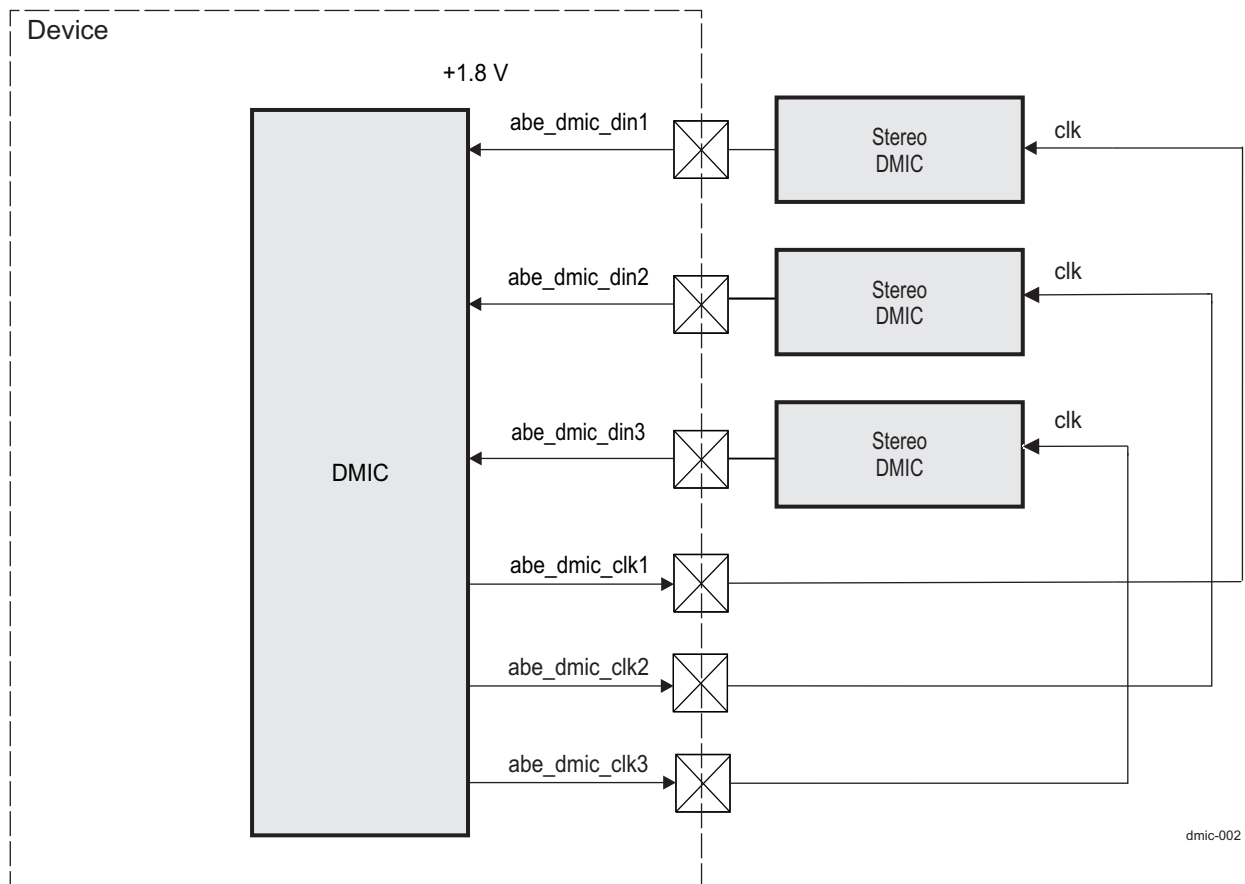

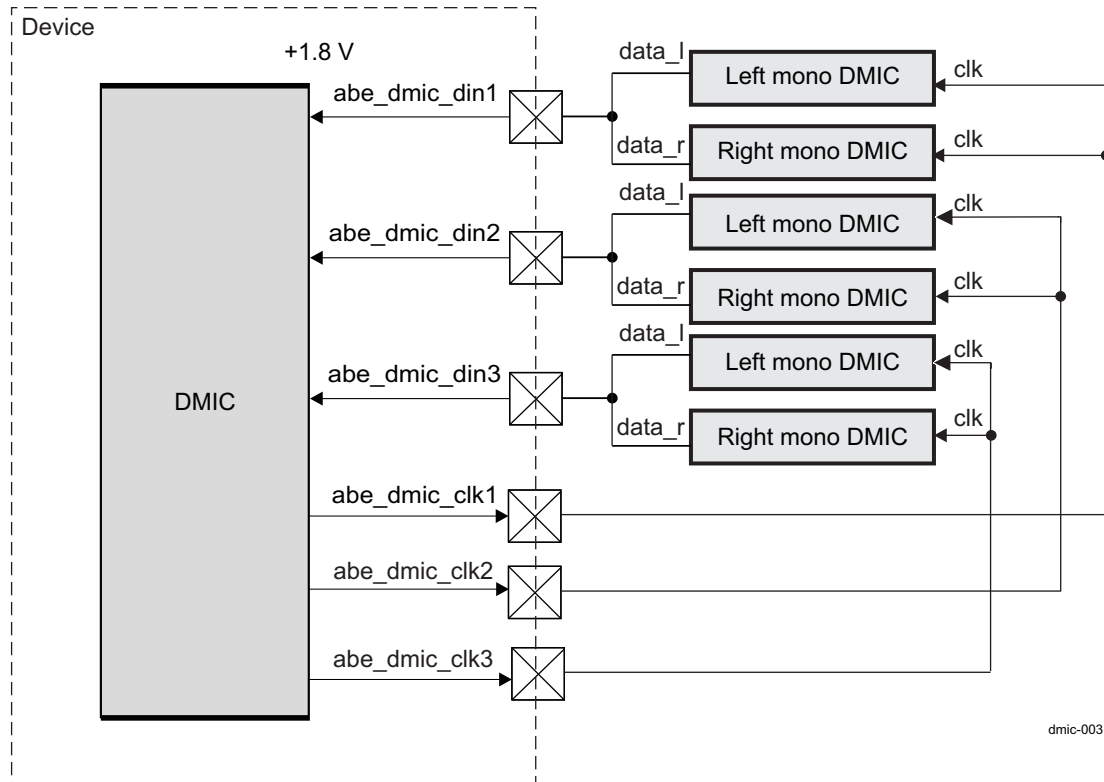

Figure 23-177 shows the DMIC used with six mono DMICs.

Figure 23-177. DMIC With Six Mono DMICs

### 23.7.2.1.2 DMIC Signals

Table 23-519 describes the signals in the DMIC module.

Table 23-519. Input/Output

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value <sup>(1)</sup>
abe_dmic_clk1	O	Digital (stereo) microphone clock output 1	0
abe_dmic_clk2	O	Digital (stereo) microphone clock output 2	0
abe_dmic_clk3	O	Digital (stereo) microphone clock output 3	0
abe_dmic_din1	I	Digital (stereo) microphone data input 1	Hi-Z
abe_dmic_din2	I	Digital (stereo) microphone data input 2	Hi-Z
abe_dmic_din3	I	Digital (stereo) microphone data input 3	Hi-Z

<sup>(1)</sup> I = Input; O = Output; Hi-Z = High impedance

All DMIC external connections have pullup or pulldown resistors, selected and configured in the control module registers.

### 23.7.2.1.3 Serial Data Format

The DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock. Then, the filter decimator extracts the 24-bit audio samples.

#### 23.7.2.1.3.1 DMIC Clock Generation and Synchronization

When DMIC\_POLAR is set to 0, the microphone left data is generated on the abe\_dmic\_clk low level. When DMIC\_POLAR is set to 1, the microphone left data is generated on the abe\_dmic\_clk high level. There are three DMIC\_POLAR<sub>x</sub> bits (where x = 1, 2, or 3) corresponding to the three stereo paths:

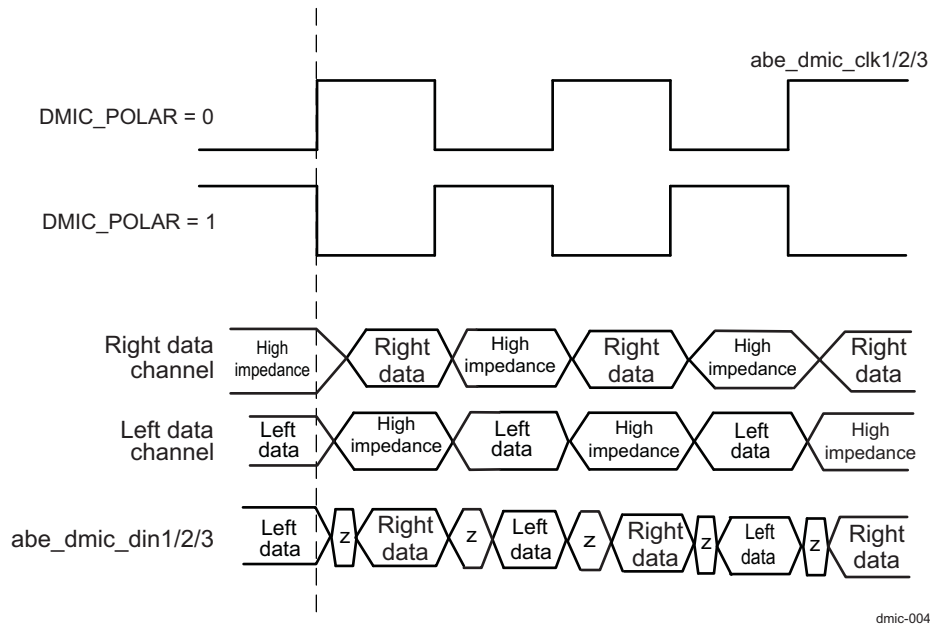

- **DMIC\_CTRL[4]** for path 1

- DMIC\_CTRL[5] for path 2
- DMIC\_CTRL[6] for path 3

The DMIC\_POLARx bits are set depending on the configuration of the external digital microphone.

Figure 23-178 is a diagram of the DMIC interface with a DMIC.

**Figure 23-178. DMIC Interface Diagram With External DMICs**

### 23.7.2.2 DMIC Functional Path

The DMIC path processes, decimates, and filters the data from the DMIC interface, and stores the processed data in the FIFO. The FIFO is controlled by IRQ and DMA requests and is fed outside of the DMIC.

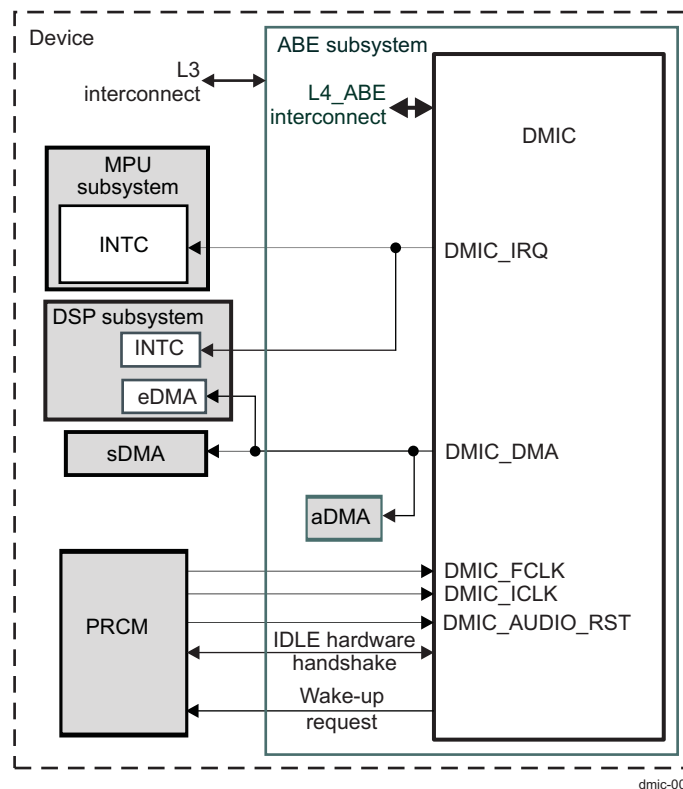

For more information about microphone data processing, see [Section 23.7.4.7, Audio Data Processing](#).

### 23.7.3 DMIC Integration

This section describes the integration of the DMIC in the device, and includes information about clocks, resets, and hardware requests.

Figure 23-179 shows the DMIC integration.

**Figure 23-179. DMIC Integration**

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The DMIC integration includes:

- One functional clock
- One interface clock
- One IRQ
- One sDMA/aDMA/eDMA request
- IDLE hardware handshake
- Wake-up request

[Table 23-520](#) through [Table 23-522](#) summarize the integration of the module in the device.

**Table 23-520. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
DMIC	PD_AUDIO	Yes	L4_ABE

**Table 23-521. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DMIC	DMIC_ICLK	ABE_ICLK2	PRCM	Interface clock
	DMIC_FCLK	DMIC_ABE_FCLK	PRCM	Functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DMIC	DMIC_AUDIO_RST	AUDIO_RST	PRCM	Module hardware reset, nonretention

**Table 23-522. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
DMIC	DMIC_IRQ	D_IRQ_83	DSP	DMIC interrupt to the DSP subsystem
	DMIC_IRQ	MA_IRQ_114	Cortex™-A9 MPU	DMIC interrupt to the Cortex-A9 MPU subsystem
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
DMIC	DMIC_DMA	S_DMA_66	sDMA	DMA request to the system DMA (sDMA)
	DMIC_DMA	A_DMA_1	aDMA	DMA request to the audio DMA (aDMA)
	DMIC_DMA	D_DMA_44	eDMA	DMA request to the DSP DMA (eDMA)

**NOTE:**

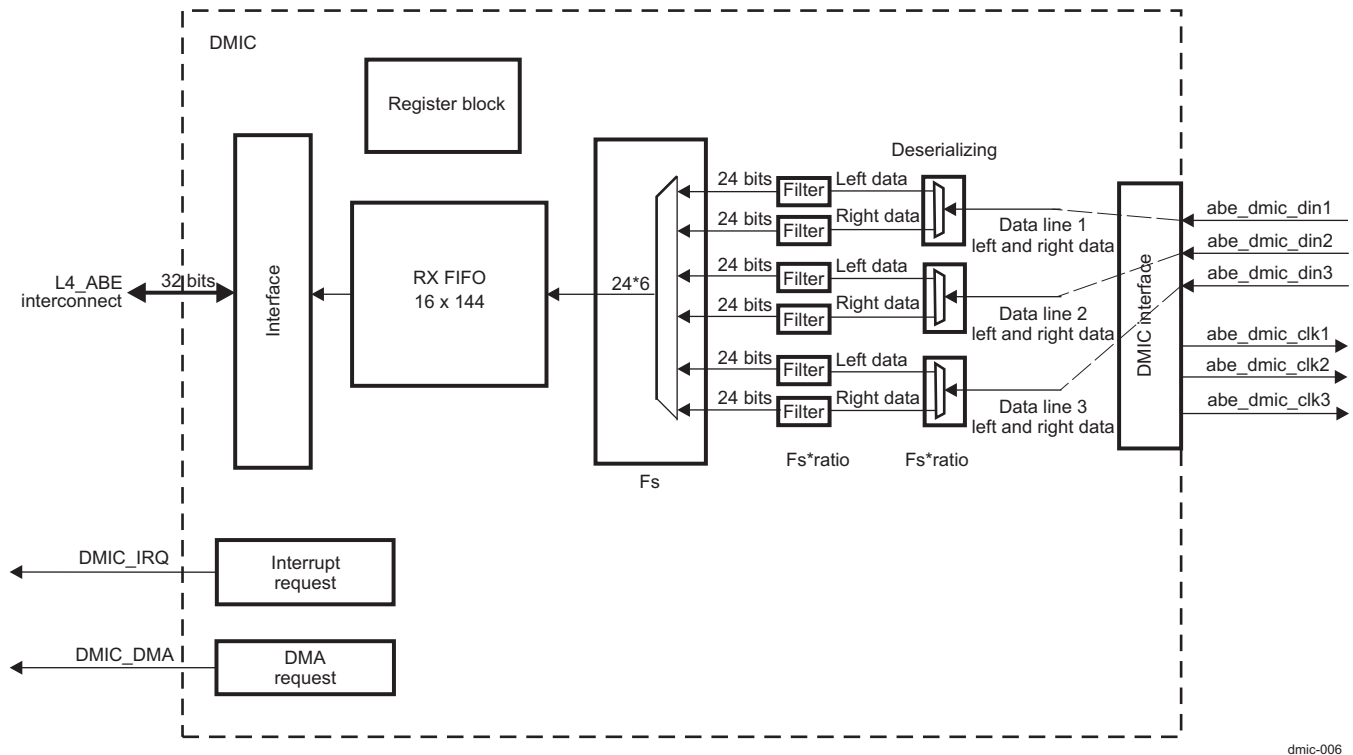

- For a description of the interrupt source, see [Section 23.7.4.5, Interrupt Requests](#).
- For a description of the DMA source, see [Section 23.7.4.6, DMA Requests](#).
- For information about PRCM clock gating and management and PRCM reset sources and distribution, see [Section 3.1.1.2.1, Power Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

## 23.7.4 DMIC Functional Description

### 23.7.4.1 Block Diagram

Figure 23-180 is the DMIC block diagram.

Figure 23-180. DMIC Block Diagram

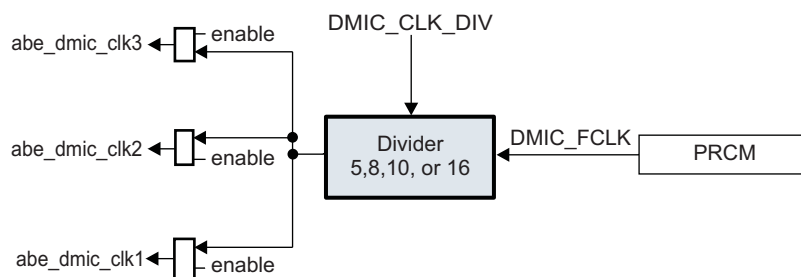

dmic-006

### 23.7.4.2 DMIC Clock Configuration

The DMIC operates from one interface clock to interface with the L4-ABE interconnect and one selectable (among three) functional clock. These clocks are provided by the PRCM module. For the interface clock, request and acknowledge are set up between the PRCM module and the DMIC.

Figure 23-181 shows the DMIC clock selection.

Figure 23-181. DMIC Clock Selection

dmic-007

DMIC\_FCLK is the source clock signal. Several source clocks are available and are selected according to the configuration of the [DMIC\\_CTRL\[9:7\] DMIC\\_CLK\\_DIV](#) bit field. For more information about DMIC\_FCLK selection, see [Figure 23-181](#). `abe_dmic_clkx` are the output clocks generated in the DMIC and are fed to the external microphones. They are also the internal clocks of the external microphones. The performance in terms of signal-to-noise ratio (SNR) depends on these clocks. Users must take care about the value of `abe_dmic_clkx` (the analog-to-digital converter [ADC] clock) when selecting the source clock (DMIC\_FCLK). FS is the output sample rate from DMIC. For example, when DMIC\_FCLK = 19.2 MHz and [DMIC\\_CTRL\[9:7\] DMIC\\_CLK\\_DIV](#) = 000, the Ratio is 25, DMIC is providing a 96 KHz sampling rate to the AESS or SDMA. [Table 23-523](#) describes the `abe_dmic_clkx` generation.

**Table 23-523. `abe_dmic_clkx` Generation**

DMIC_FCLK	DMIC_CLK_DIV	Ratio DMIC_FCLK/ <code>abe_dmic_clk</code>	<code>abe_dmic_clk</code> = ADC Clock	FS	Ratio = <code>abe_dmic_clk</code> /FS = 96 kHz
19.2/17.64 MHz	000	8	2.4/2.205 MHz	96/88.2 KHz	25
	001	5	3.84/3.528 MHz	96/88.2 KHz	40
19.2 MHz	110	5	3.84 MHz	192 KHz	20
24 MHz	010	10	2.4 MHz	96 KHz	25
24.576 MHz	011	8	3.072 MHz	96 KHz	32
	100	16	1.536 MHz	96 KHz	16
12 MHz	101	5	2.4 MHz	96 KHz	25

The maximum clock on the interface is 3.84 MHz, with a source clock of 19.2 MHz.

### 23.7.4.3 DMIC Software Reset

[Table 23-524](#) lists the different types of software reset available at the module level.

**Table 23-524. Reset Description**

Type	Name	Source	Description
Software	<a href="#">DMIC_SYSCONFIG[1] SOFTRESET</a>	–	Module software reset
Software	<a href="#">DMIC_CTRL[10] SW_DMIC_RST</a>	–	Reset-enabled DMIC paths

The software path reset is gated by:

- [DMIC\\_CTRL\[0\] DMIC\\_UP1\\_EN](#) for path 1
- [DMIC\\_CTRL\[1\] DMIC\\_UP2\\_EN](#) for path 2
- [DMIC\\_CTRL\[2\] DMIC\\_UP3\\_EN](#) for path 3
- [DMIC\\_CTRL\[10\] SW\\_DMIC\\_RST](#)

When the [DMIC\\_CTRL\[10\] SW\\_DMIC\\_RST](#) bit is set to 1, the corresponding enabled DMIC paths are reset. Resets are cleared by writing 0.

---

**NOTE:** A software reset is required to change the configuration of enabled paths; for example, to disable path 3, a software reset of path 3 is mandatory for the change to be considered.

---

A module software reset can be performed by setting the [DMIC\\_SYSCONFIG\[1\] SOFTRESET](#) bit. This action starts a soft reset sequence.

The software reset status of the module can be checked by reading the [DMIC\\_SYSCONFIG\[0\] SOFTRESET](#) bit (0: reset is done; 1: reset is ongoing).

### 23.7.4.4 DMIC Power Management

[Table 23-525](#) describes the power-management features available for the DMIC.

**Table 23-525. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	N/A	Feature not available
Slave idle modes	<a href="#">DMIC_SYSCONFIG</a> [3:2] SIDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup capable modes are available.
Clock activity	N/A	Feature not available
Master standby modes	N/A	Feature not available
Global wake-up enable	N/A	Feature not available
Wake-up sources enable	<a href="#">DMIC_IRQWAKEEN</a> [0] IRQ_WAKEUP_EN <a href="#">DMIC_DMAWAKEEN</a> [0] DMA_WAKEUP_EN	This register holds one active-high enable bit per event source that can generate a wake-up signal.

#### 23.7.4.5 DMIC Interrupt Requests

[Table 23-526](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 23-526. Interrupt Events**

Nonmaskable Event Flag <sup>(1)</sup>	Maskable Event Flag	Event Mask Bit	Event Unmask Bit	Description
<a href="#">DMIC_IRQSTATUS_RAW[3]</a> DMIC_IRQ_EMPTY	<a href="#">DMIC_IRQSTATUS[3]</a> DMIC_IRQ_EMPTY	<a href="#">DMIC_IRQENABLE_CLR[3]</a> DMIC_IRQ_EMPTY_MASK	<a href="#">DMIC_IRQENABLE_SET[3]</a> DMIC_IRQ_EMPTY_MASK	FIFO empty event. This event occurs when the FIFO is already empty and a new word is read from the FIFO by software.
<a href="#">DMIC_IRQSTATUS_RAW[2]</a> DMIC_IRQ_ALST_FULL	<a href="#">DMIC_IRQSTATUS[2]</a> DMIC_IRQ_ALST_FULL	<a href="#">DMIC_IRQENABLE_CLR[2]</a> DMIC_IRQ_ALST_FULL_MASK	<a href="#">DMIC_IRQENABLE_SET[2]</a> DMIC_IRQ_ALST_FULL_MASK	FIFO almost-full event. This event occurs when the FIFO contains (FIFO size – 1) words and a new word is written to the FIFO.
<a href="#">DMIC_IRQSTATUS_RAW[1]</a> DMIC_IRQ_FULL	<a href="#">DMIC_IRQSTATUS[1]</a> DMIC_IRQ_FULL	<a href="#">DMIC_IRQENABLE_CLR[1]</a> DMIC_IRQ_FULL_MASK	<a href="#">DMIC_IRQENABLE_SET[1]</a> DMIC_IRQ_FULL_MASK	FIFO full event. This event occurs when the FIFO is already full and a new word is written to the FIFO.
<a href="#">DMIC_IRQSTATUS_RAW[0]</a> DMIC_IRQ	<a href="#">DMIC_IRQSTATUS[0]</a> DMIC_IRQ	<a href="#">DMIC_IRQENABLE_CLR[0]</a> DMIC_IRQ_MASK	<a href="#">DMIC_IRQENABLE_SET[0]</a> DMIC_IRQ_MASK	FIFO read request event. This event occurs when the number of words stored in the FIFO is equal to or greater than the FIFO threshold.

<sup>(1)</sup> The [DMIC\\_IRQSTATUS\\_RAW](#) register is used primarily for debug purposes.

The interrupt line is asserted (active high) when one of the following signals appears:

- [DMIC\\_IRQ\\_EMPTY](#)
- [DMIC\\_IRQ\\_ALST\\_FULL](#)
- [DMIC\\_IRQ\\_FULL](#)
- [DMIC\\_IRQ](#)

Read the [DMIC\\_IRQSTATUS](#) register to determine which event occurs.

**CAUTION**

Interrupt lines must be cleared by software. Write 1 in the [DMIC\\_IRQSTATUS](#) register to clear the corresponding event.

An event can generate an IRQ when the corresponding mask bit in the [DMIC\\_IRQENABLE\\_SET](#) register is set to 1. Events are register bits that belong to the [DMIC\\_IRQSTATUS](#) and [DMIC\\_IRQSTATUS\\_RAW](#) registers (the same register accessed by two interconnect addresses). In the case of the [DMIC\\_IRQSTATUS\\_RAW](#) register, status event is set even if it is not enabled (used primarily for debug purposes). The [DMIC\\_IRQSTATUS](#) register is set by writing 1 to the [DMIC\\_IRQSTATUS\\_RAW](#) register.

Each internal interrupt signal can be masked by enabling the corresponding mask in the [DMIC\\_IRQENABLE\\_SET](#) register or disabling it in the [DMIC\\_IRQENABLE\\_CLR](#) register. This mechanism is defined in [Section 23.7.6, DMIC Register Manual](#).

[Figure 23-182](#) shows the interrupt tree with the event generated and the mask that enables or disables the event. All events are summarized to give the single interrupt generation.

Figure 23-182. Interrupt Tree

dmic-008

#### 23.7.4.6 DMIC DMA Requests

The DMIC can generate one DMA request to the sDMA, aDMA, and eDMA controllers (see [Table 23-527](#)).

**Table 23-527. DMIC DMA Request**

Name	Description	Enable DMA Bit	Disable DMA Bit
DMIC_DMA_ENABLE	Data ready in FIFO (threshold is reached)	<a href="#">DMIC_DMAENABLE_SET</a> [0] DMA_ENABLE	<a href="#">DMIC_DMAENABLE_CLR</a> [0] DMA_ENABLE

The DMA lines can be enabled or disabled depending on the value of the bits in the [DMIC\\_DMAENABLE\\_SET](#) and [DMIC\\_DMAENABLE\\_CLR](#) registers.

A DMA request is sent when data is ready in the FIFO. This request is used only to notify the host that data are ready in the FIFO.

#### 23.7.4.7 Audio Data Processing

The DMIC supports six audio paths and can be used with three stereo or six mono microphones. Each path is independent and is enabled or disabled by using the following bits:

- [DMIC\\_CTRL](#)[0] DMIC\_UP1\_EN
- [DMIC\\_CTRL](#)[1] DMIC\_UP2\_EN
- [DMIC\\_CTRL](#)[2] DMIC\_UP3\_EN

##### 23.7.4.7.1 Filtering

The external DMIC generates a PDM stream of bits and transfers it in one period or one half-period of the clock provided by the DMIC inside the device. The aim of the DMIC audio path is to process data from the DMIC interface, decimate and filter the data, and store the processed data in the FIFO.

The format of the DMIC data is 24 bits (the transfer format is 32 bits long). The following bits allow switching the polarity of the interface:

- [DMIC\\_CTRL](#)[4] DMIC\_POLAR1
- [DMIC\\_CTRL](#)[5] DMIC\_POLAR2
- [DMIC\\_CTRL](#)[6] DMIC\_POLAR3

For more information, see [Section 23.7.2.1.3.1, DMIC Clock Generation and Synchronization](#).

Processed data from the DMIC interface are stored in the FIFO. The FIFO is controlled by the IRQ and DMA request and externally fed by the DMIC using the following interconnect format.

The three uplink paths are identical. Each uplink path is composed of a left and a right channel. The DMIC interface delivers six parallel data of 1 bit (3 × 2 paths of stereo data that can be used at six mono paths). Each bit goes to a filter. The aim of the filter is to limit the noise and perform decimation by factor D. Factor D depends on the [DMIC\\_CLK\\_DIV](#) register bits, as described in the ratio defined in [Table 23-523](#). The filters are sinc filter order 4. They are chosen with regard to the nature of the analog converter.

The format of the filter output is 24 bits.

#### 23.7.4.8 FIFO Management

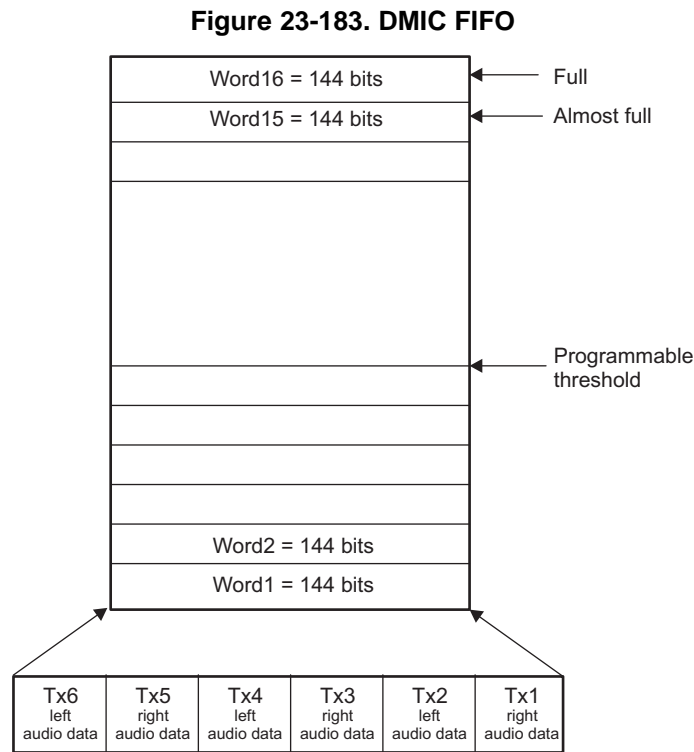

The DMIC implements an internal FIFO controlled by IRQ and DMA request. The host must read words in the FIFO. The interrupt line is used not only to inform the host that data are ready in the FIFO, but also to warn the host about events that can occur, such as FIFO full, almost full, or empty. A DMA request is used only to inform the host that data are ready in the FIFO.

##### 23.7.4.8.1 FIFO General Description

The DMIC communicates with the host through L4-ABE interconnect access. DMIC audio data coming from external microphones are stored in the FIFO. The DMIC FIFO allows the exchange of information between the DMIC and the host. Each audio data is 24 bits long. The DMIC FIFO contains 16 words. Each word is the combination of six audio data (24 × 6 = 144 bits) coming from the interface. The FIFO is controlled by interrupt lines and DMA requests. For more information about IRQs and DMA controls, see [Section 23.7.4.5, DMIC Interrupt Requests](#), and [Section 23.7.4.6, DMIC DMA Requests](#).

FIFO write access is done in the functional clock domain, and read access is done in the interface clock domain.

Figure 23-183 is an overview of the DMIC FIFO.

dmic-009

### 23.7.4.8.2 FIFO Operations

Audio data are filled in the FIFO from DMIC internal filters. The host must read words in the FIFO. The number of reads depends on the application that is configured by the following bits:

- [DMIC\\_CTRL\[0\]](#) DMIC\_UP1\_EN
- [DMIC\\_CTRL\[2\]](#) DMIC\_UP3\_EN
- [DMIC\\_CTRL\[1\]](#) DMIC\_UP2\_EN
- [DMIC\\_FIFO\\_CTRL\[3:0\]](#) DMIC\_TRESH (FIFO threshold)

If only uplink path 2 and path 3 are enabled, for example, the Tx1 and Tx2 words are left and right data for path 2, and Tx3 and Tx4 are left and right data for path 3.

When the FIFO threshold is reached, and depending on conditions, an event is sent to the DMA handler. The host must read the exact number of words in the FIFO.

Two accesses are required to read a complete stereo audio path.

The number of read accesses from the host is determined by the following equation:

$$\text{Num\_rd\_access} = (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2 \times (\text{DMIC\_TRESH})$$

The FIFO threshold is programmed through the [DMIC\\_FIFO\\_CTRL\[3:0\]](#) DMIC\_TRESH bit field.

---

**NOTE:** If DMIC\_TRESH = 1, the host is expected to perform  $1 \times (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2$  read access every 96 kHz ( $2 \times \text{FS}$ ).

If DMIC\_TRESH = 2, the host is expected to perform  $(\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 4$  read access every 48 kHz (FS).

If DMIC\_TRESH = 12, the host is expected to perform  $(\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 12$  access every 8 kHz ( $\text{FS}/6$ ).

---

### 23.7.4.8.3 FIFO Output Range Definition

The [DMIC\\_CTRL\[3\]](#) DMICOUTFORMAT bit allows determining the format of the output of the DMIC uplink module.

When DMICOUTFORMAT = 0, the data going from the FIFO are left-shifted by 8 bits. When DMICOUTFORMAT = 1, the data are signed-extended on 32 bits.

The DMIC uplink modules process audio data based on twos complement format.

---

**NOTE:** When DMICOUTFORMAT = 0, the maximum positive swing analog voltage corresponds to a final DMIC output of 0x7FFF FF00. The maximum negative swing analog voltage corresponds to a final DMIC output of 0x8000 0000.

When DMICOUTFORMAT = 1, the sign is extended: The maximum positive swing analog voltage corresponds to a final DMIC output of 0x007F FFFF. The maximum negative swing analog voltage corresponds to a final DMIC output of 0xFF80 0000.

---

Reading the value of the corresponding audio data in the FIFO requires access to the [DMIC\\_DATA\\_REG](#) register. The first access gives the value of Tx1 right data, the second gives the value of Tx2 left data, up to Tx6 (the left audio data of the last audio path). If the path is disabled, 0x0 is read. All data are duplicated (for debug purposes) in their corresponding left or right data registers. [Table 23-528](#) describes the audio data path registers.

**Table 23-528. Audio Data Path Registers**

Stereo Audio Path	Mono Audio Path	Data Register
Right path 1	Mono path 1	<a href="#">DMIC_FIFO_DMIC1R_DATA[23:0]</a>
Left path 1	Mono path 2	<a href="#">DMIC_FIFO_DMIC1L_DATA[23:0]</a>
Right path 2	Mono path 3	<a href="#">DMIC_FIFO_DMIC2R_DATA[23:0]</a>
Left path 2	Mono path 4	<a href="#">DMIC_FIFO_DMIC2L_DATA[23:0]</a>
Right path 3	Mono path 5	<a href="#">DMIC_FIFO_DMIC3R_DATA[23:0]</a>
Left path 3	Mono path 6	<a href="#">DMIC_FIFO_DMIC3L_DATA[23:0]</a>

The output of the DMIC path for interconnect access is in 32-bit format.

## 23.7.5 DMIC Programming Guide

### 23.7.5.1 DMIC Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 23.7.5.1.1 Global Initialization

##### 23.7.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the DMIC is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMIC. For more information, see [Section 23.7.3, DMIC Integration](#) and [Section 23.7.2, DMIC Environment](#).

[Table 23-529](#) describes the global initialization of surrounding modules.

**Table 23-529. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing must be set in the control module. See <a href="#">Chapter 18, Control Module</a> .
(optional) Cortex-A9 MPU interrupt controller (INTC) (or DSP INTC)	INTC configuration must be done to enable the interrupts from the DMIC. See <a href="#">Chapter 17, Interrupt Controllers</a> .
(optional) sDMA (or eDMA or aDMA)	DMA configuration must be done to enable the DMIC DMA channel requests.
(optional) Interconnect	For more information about the interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .

---

**NOTE:** The INTC and DMA configurations are necessary if the interrupt and DMA-based communication modes are used.

---

#### 23.7.5.1.1.2 DMIC Global Initialization

##### 23.7.5.1.1.2.1 Main Sequence – DMIC Global Initialization

The procedure in [Table 23-530](#) initializes the DMIC after a power-on reset (POR).

**Table 23-530. DMIC Global Initialization**

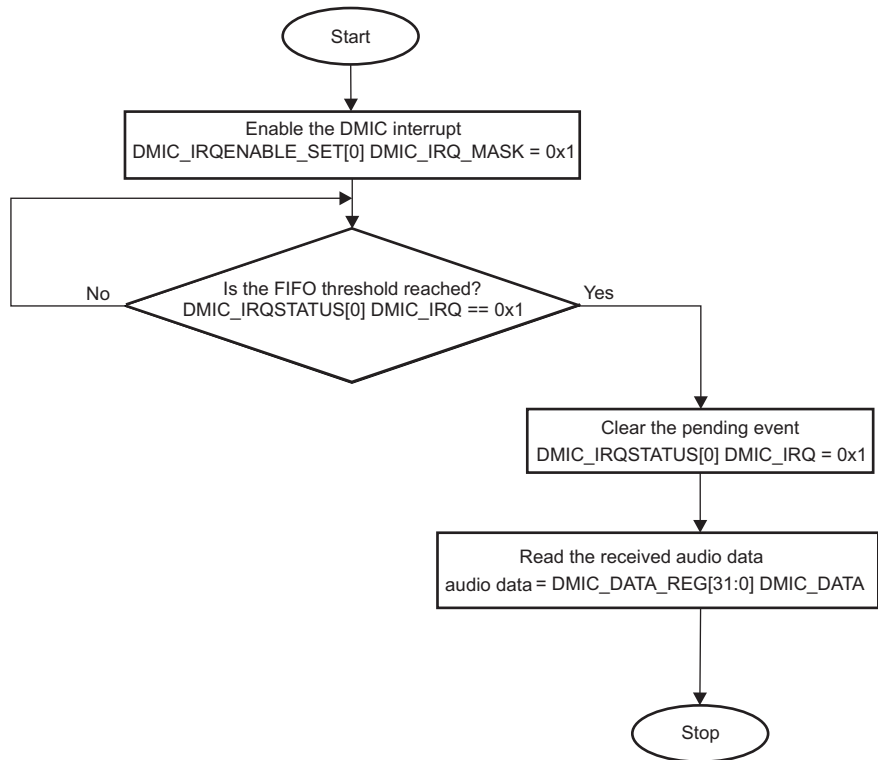

Step	Register/Bit Field/Programming Model	Value
Execute a software reset.	DMIC_SYSCONFIG[0] SOFTRESET	0x1
Wait for the software reset completion by polling.	DMIC_SYSCONFIG[0] SOFTRESET	==0x0
Configure the local power management.	DMIC_SYSCONFIG[3:2] SIDLEMODE	0x-
Select the DMIC FIFO threshold.	DMIC_FIFO_CTRL[3:0] DMIC_TRESH	0x-
Select the DMIC output clock frequency.	DMIC_CTRL[9:7] DMIC_CLK_DIV	0x-
Select the DMIC FIFO data output format.	DMIC_CTRL[3] DMICOUTFORMAT	0x-
Select the level (high or low) of the clock signal <code>abe_dmic_clki</code> when the left data is to be generated (extracted) from the external microphone <code>i</code> (where <code>i = 1 to 3</code> ).	DMIC_CTRL[j] DMIC_POLAR <sub>i</sub> (where <code>j = 4 to 6</code> , and <code>i = 1 to 3</code> )	0x-
Enable audio path <code>i</code> (where <code>i = 1 to 3</code> ).	DMIC_CTRL[k] DMIC_POLAR <sub>i</sub> (where <code>k = 0 to 2</code> , and <code>i = 1 to 3</code> )	0x1

23.7.5.1.2 Operational Mode Configuration

23.7.5.1.2.1 DMIC Polling Mode

Figure 23-184 shows the polling mode. Table 23-531 summarizes the register call for the polling mode. For the number of read accesses used while reading the received audio data, see Section 23.7.4.8, FIFO Management.

Figure 23-184. Polling Mode

dmic-010

Table 23-531. Register Call Summary for Polling Mode

Register Name	Register Name	Register Name
DMIC_IRQENABLE_SET	DMIC_IRQSTATUS	DMIC_DATA_REG

23.7.5.1.2.2 DMIC Interrupt Mode

Table 23-532 lists the procedure to initialize interrupt mode.

Table 23-532. Interrupt Mode

Step	Register/Bit Field/Programming Model	Value
Enable the DMIC interrupts.	DMIC_IRQENABLE_SET[3:0]	0xF

23.7.5.1.2.3 DMIC DMA Mode

Table 23-533 lists the procedure to initialize DMA mode.

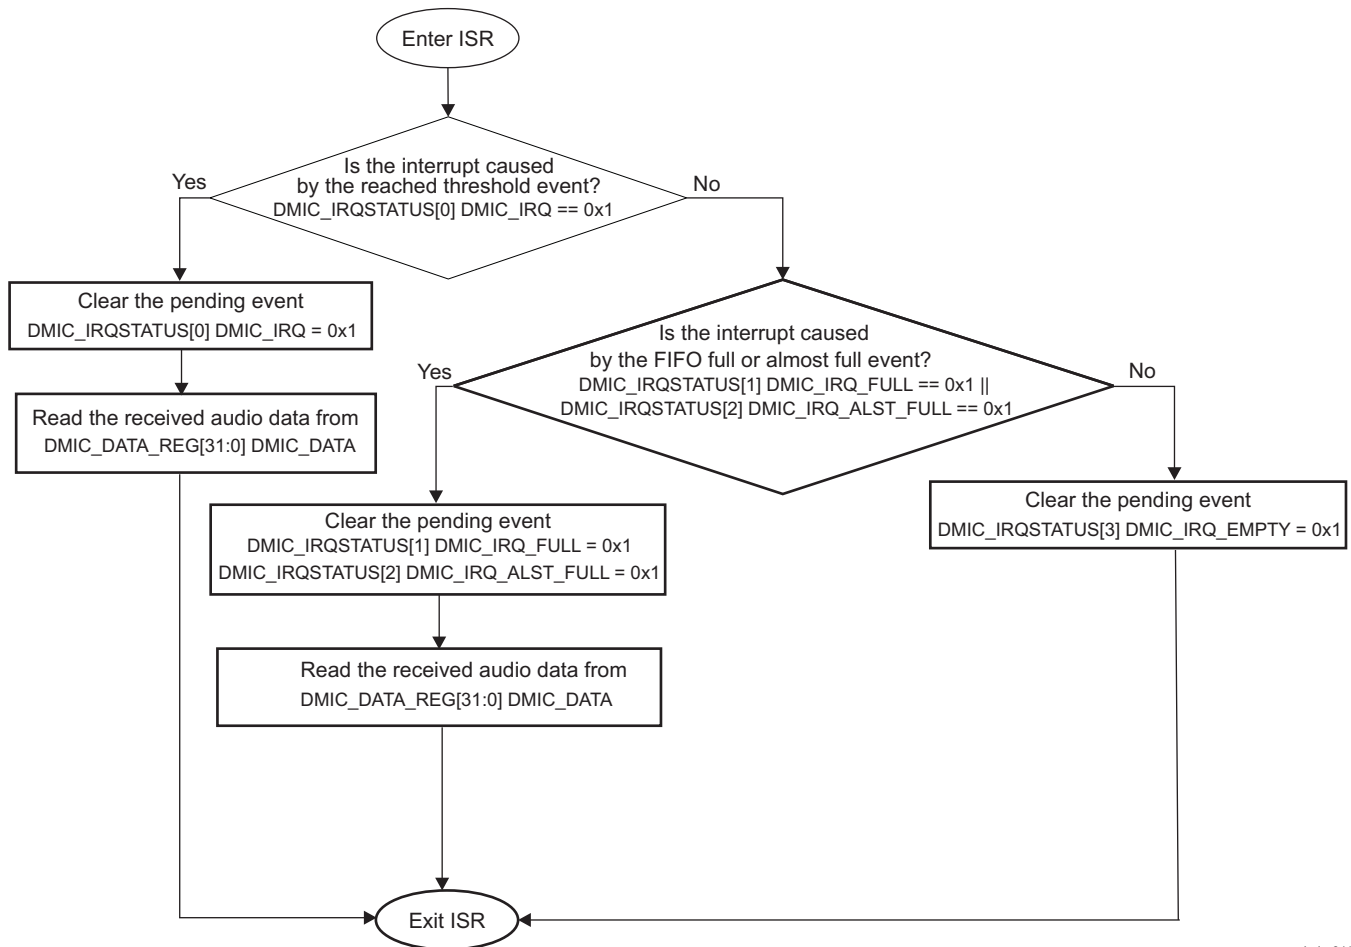

**Table 23-533. DMA Mode**

Step	Register/Bit Field/Programming Model	Value
Enable the DMIC DMA interrupt event.	DMIC_DMAENABLE_SET[0] DMA_ENABLE	0x1

### 23.7.5.1.3 DMIC Events Servicing

#### 23.7.5.1.3.1 DMIC Interrupt Servicing

This section describes the interrupt event servicing of the module. Figure 23-185 shows the interrupt handler.

**Figure 23-185. Interrupt Handler**

dmic-011

When the interrupt is caused by the reached threshold event, for the number of read accesses used while reading the received audio data, see Section 23.7.4.8, *FIFO Management*.

When the interrupt is caused by a FIFO full or almost-full event, software must read all the available data in the FIFO. If a FIFO full event occurred, the number of read accesses must be the maximum:

$$\text{Num\_rd\_access} = (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2 \times 15$$

If a FIFO almost-full event occurred, the number of read accesses must be:

$$\text{Num\_rd\_access} = (\text{DMIC\_UP1\_EN} + \text{DMIC\_UP2\_EN} + \text{DMIC\_UP3\_EN}) \times 2 \times 14$$

Table 23-534 summarizes the register call for the interrupt handler.

**Table 23-534. Register Call Summary for the Interrupt Handler**

Register Name	Register Name
<a href="#">DMIC_IRQSTATUS</a>	<a href="#">DMIC_DATA_REG</a>

## 23.7.6 DMIC Register Manual

### 23.7.6.1 DMIC Instance Summary

Table 23-535 is the DMIC instance summary.

**Table 23-535. DMIC Instance Summary**

Module Name	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Size
DMIC	0x4902 E000	0x4012 E000	0x2 E000	4KB

**NOTE:** Private access is an access that does not use the L3/L4 interconnects.

### 23.7.6.2 DMIC Registers

#### 23.7.6.2.1 DMIC Register Summary

Table 23-536 summarizes the DMIC register mapping.

**Table 23-536. DMIC Register Mapping Summary**

## 23.8 Multichannel Audio Serial Port

This section describes the multichannel audio serial port (McASP).

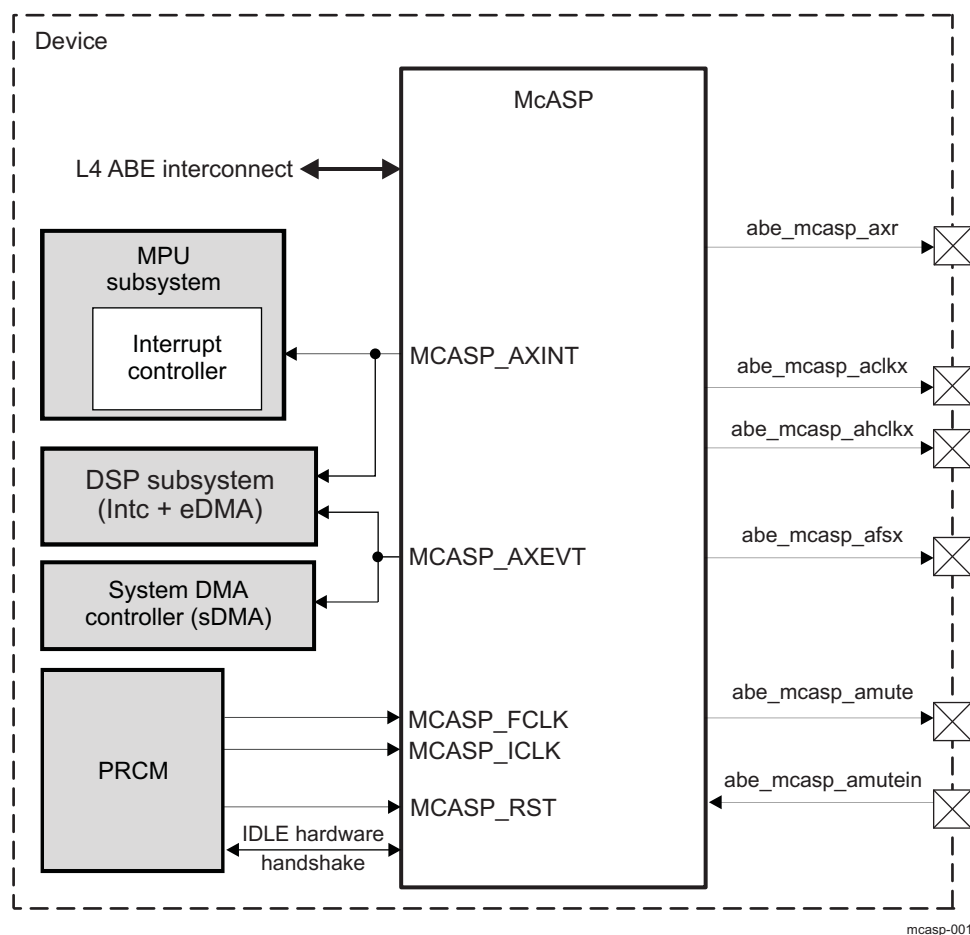

### 23.8.1 McASP Overview

This section introduces the multichannel audio serial port (McASP) module and describes its main functions and connections in the device.

The McASP functions as a general-purpose audio serial port optimized to the requirements of various audio applications. The McASP is useful for intercomponent digital audio interface transmission (DIT). The McASP has the flexibility to gluelessly connect to a Sony/Philips digital interface (S/PDIF) transmit physical layer component. The McASP module operates in transmit mode only; it has no receive capabilities.

Figure 23-186 shows the McASP module in the device.

**Figure 23-186. McASP Module**

The McASP module includes the following main features:

- Support of the idle request/acknowledge protocol
- One serializer implementing a single transmit channel
- A single 32-bit buffer in the serializer for transmit operations
- One transmit direct memory access (DMA) request linked with the serializer
- One transmit interrupt request linked with the serializer

## 23.8.2 McASP Environment

This section describes the McASP application fields from an environment point of view (external connections), along with the McASP connectivity options. This section also lists all of the possible interfaces and describes the protocol and data format used in each case.

### 23.8.2.1 McASP Signals

Table 23-575 describes the McASP signals and specifies their links to functions.

**Table 23-575. I/O**

Signal	I/O <sup>(1)</sup>	Description
abe_mcasp_axr	O	Audio transmit data
abe_mcasp_aclkx	O	Transmit bit clock
abe_mcasp_ahclkx	O	Transmit high-frequency master clock
abe_mcasp_afsx	O	Transmit frame synchronization
abe_mcasp_amute	O	Mute out to external
abe_mcasp_amutein	I	Mute in from external

<sup>(1)</sup> I = Input; O = Output

All McASP pins on the device can be individually programmed as general-purpose input/output (GPIO) if they are not used for serial port functions.

The McASP includes the following pins:

- Serializer:
  - AXR0: serial data transmission pin. The corresponding McASP signal at device level is named `abe_mcasp_axr`.
- Transmit clock generator:
  - ACLKX: McASP transmit bit clock. The corresponding McASP signal at device level is named `abe_mcasp_aclkx`.
  - AHCLKX: McASP transmit high-frequency master clock. The corresponding McASP signal at device level is named `abe_mcasp_ahclkx`.
- Transmit frame-sync generator:
  - AFSX: McASP transmit frame sync. The corresponding McASP signal at device level is named `abe_mcasp_afsx`.
- Mute in/out:
  - AMUTEIN: McASP mute input (from external device). The corresponding McASP signal at device level is named `abe_mcasp_amutein`.
  - AMUTE: McASP mute output. The corresponding McASP signal at device level is named `abe_mcasp_amute`.

---

**NOTE:** For McASP transmission, it is necessary to set the output direction for the serializer AXR0 data pin (at the device level, the signal is named `abe_mcasp_axr`) in the `MCASP_PDIR` register. The transmit function has to be selected in the corresponding serializer control register (`MCASP_XRSRCTL0`).

---

### 23.8.2.2 Protocols and Data Formats

#### 23.8.2.2.1 Protocols Supported

The McASP transmit section uses the S/PDIF industry format, which is supported by the DIT transfer mode of the module.

Each transmit section can be programmed to support the following options on the basic serial protocol:

- Programmable clock and frame-sync polarity (rising or falling edge): `abe_mcaspl_aclkx`, `abe_mcaspl_ahclkx`, and `abe_mcaspl_afsx`
- Slot length (number of bits per time slot): 8, 12, 16, 20, 24, 28, 32 bits supported
- Word length (bits per word): 8, 12, 16, 20, 24, 28, 32 bits; always less than or equal to the time slot length
- First-bit data delay: 0-, 1-, 2-bit clocks
- Left/right alignment of word inside slot
- Bit order: Most-significant bit (MSB) first or least-significant bit (LSB) first
- Bit mask/pad/rotate function
- Automatically aligns data in Q31 or integer format
- Automatically masks nonsignificant bits (sets to 0, 1, or extends value of another bit)

The DIT transfer mode includes the following additional transmitter features:

- Transmit-only mode: 384 time slots (subframe) per frame
- Biphase encoded LVCMOS output
- Channel status RAM (384 bits)
- User data RAM (384 bits)
- Separate valid bit (V) for subframes A and B

---

**NOTE:** An external transceiver must be connected to the McASP port in the device to translate the electrical signals delivered by the McASP (1.2 V or 1.8 V LVCMOS levels) to the electrical levels of the S/PDIF standard.

---

### 23.8.2.2.2 Definition of Terms

The serial bitstream transmitted by the McASP is a long sequence of 1s and 0s on an audio transmit pin (`abe_mcaspl_axr`). However, the sequence has a hierarchical organization that can be described in terms of frames of data, slots, words, and bits.

A basic synchronous serial interface consists of three important components: clock, frame sync, and data. [Figure 23-187](#) shows two of the three basic components: the clock (`abe_mcaspl_aclkx`) and the data (`abe_mcaspl_axr`). In operation, the transmitter uses `abe_mcaspl_aclkx` as serial clock.

- Bit:

A bit is the smallest entity in the serial data stream. The beginning and end of each bit is marked by an edge of the serial clock. The duration of a bit is a serial clock period. A 1 is represented by a logic high on the `abe_mcaspl_axr` pin for the entire duration of the bit. A 0 is represented by a logic low on the `abe_mcaspl_axr` pin for the entire duration of the bit.

- Word:

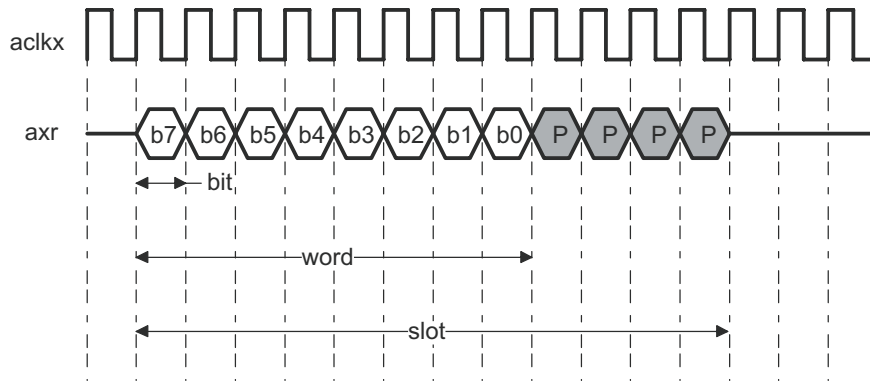

A word is a group of bits that make up the data being transferred between the McASP and the external device. [Figure 23-187](#) shows an 8-bit word.

- Slot:

A slot consists of the bits that make up the word and can consist of additional bits used to pad the word to a convenient number of bits for the interface between the McASP and the external device. In [Figure 23-187](#), the audio data consists of only 8 bits of useful data (8-bit word), but it is padded with four 0s (12-bit slot) to satisfy the desired protocol in interfacing to an external device. Within a slot, the bits can be shifted out of the McASP on the `abe_mcaspl_axr` pin with either MSB or LSB first.

When the word size is smaller than the slot size, the word can be aligned to the left of the slot (beginning) or to the right of the slot (end). The additional bits in the slot not belonging to the word can be padded with 0, 1, or with one of the bits (typically, the MSB or LSB) from the data word (that is, left-aligned words within a slot are terminated with padding bits and right-aligned words within a slot are preceded by padding bits to fit in the slot size). [Figure 23-188](#) shows these options.

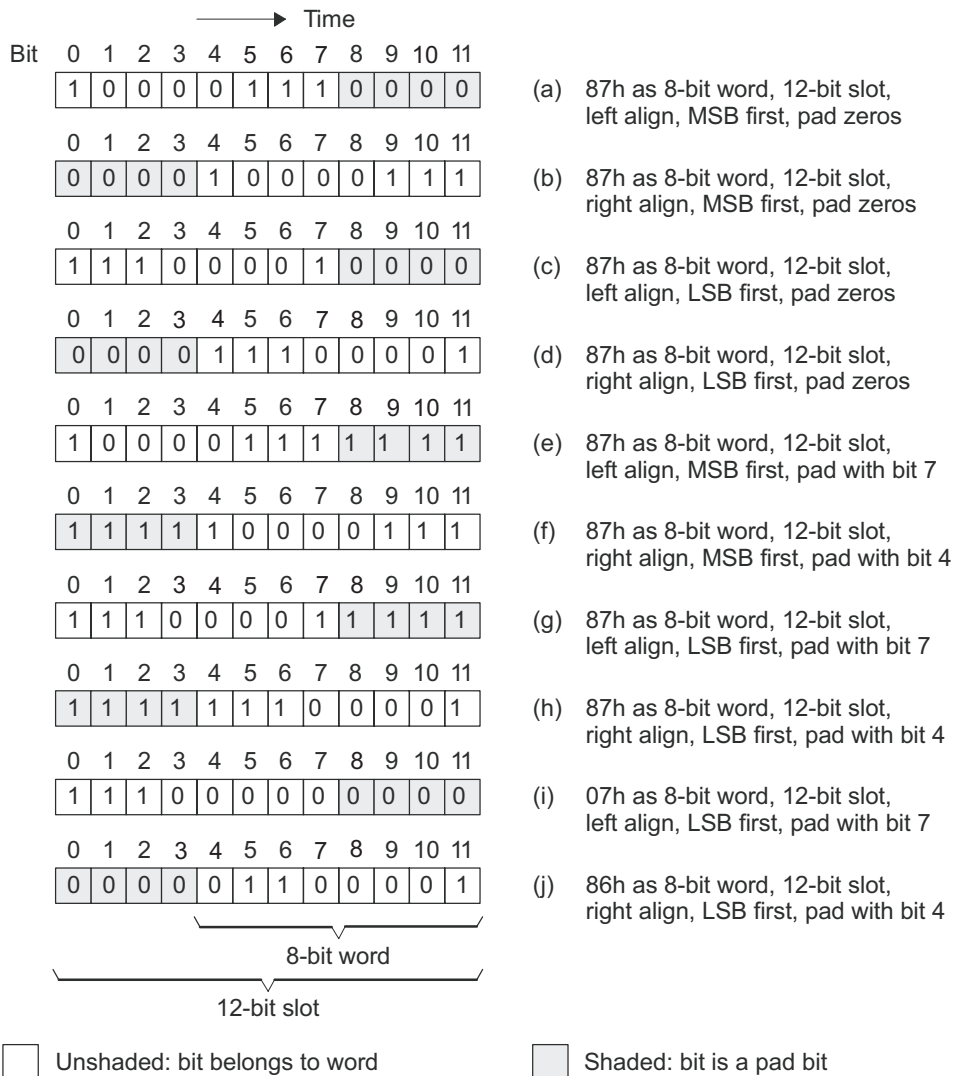

Figure 23-187. Definition of Bit, Word, and Slot

- (1) b7:b0 - bits. Bits b7 to b0 form a word.
- (2) P - pad bits. Bits b7 to b0, together with the 4 pad bits, form a slot.
- (3) In this example, the data is transmitted MSB first, left-aligned.

mccasp-010

Figure 23-188. Bit Order and Word Alignment Within a Slot Examples

mccasp-008

- Frame

The third basic element of a synchronous serial interface is the frame synchronization signal, also referred to as frame sync in this document. A frame contains one or multiple slots, as determined by the desired protocol. [Figure 23-189](#) shows an example frame of data and the frame definitions. In operation, the transmitter uses `abe_mcaspx_afsx`. This example shows two slots in a frame and the frame-sync (FS) duration of the slot length.

This section shows only the generic definition of the frame sync. For more information about the frame-sync formats required for the transfer modes and protocols (DIT mode and S/PDIF format), see [Section 23.8.2.2.3, Frame Format](#).

**Figure 23-189. Definition of Frame and Frame-Sync Width**

The following terms are used throughout this chapter:

- DIT: Digital audio interface transmit. The McASP supports transmitting in S/PDIF format on the `abe_mcaspx_axr` data pin.
- Slot or time slot: For DIT format, a McASP time slot corresponds to a DIT subframe.

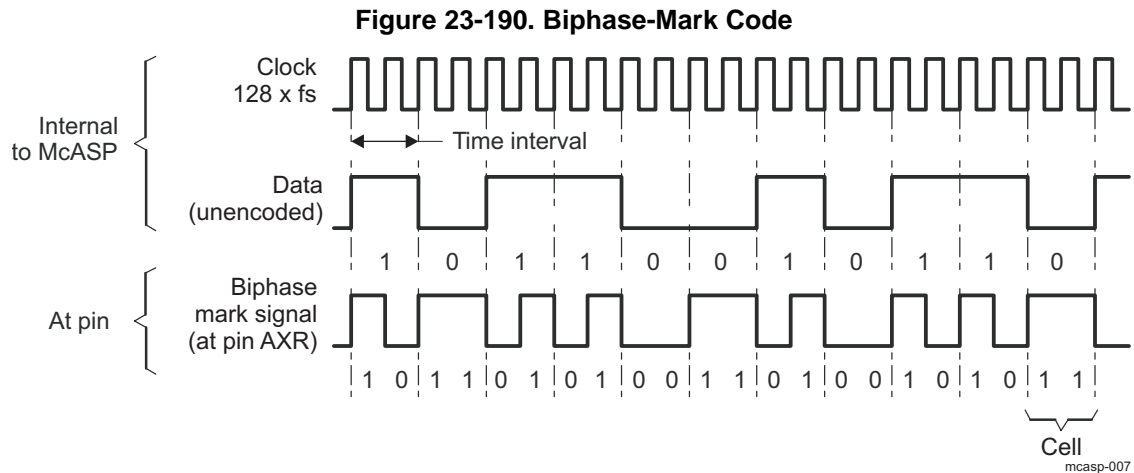

### 23.8.2.2.3 S/PDIF Coding Format

The McASP transmitter supports the S/PDIF format with 1.8-V biphasemark encoded output. The S/PDIF format is supported by the DIT transfer mode of the McASP. This section briefly discusses the S/PDIF coding format.

#### 23.8.2.2.3.1 Biphasemark Code

In S/PDIF format, the digital signal is coded using the biphasemark code (BMC). The clock, frame, and data are embedded in only one signal: data pin `abe_mcaspx_axr`. In the BMC system, each data bit is encoded into two logical states (00, 01, 10, or 11) at the pin. These two logical states form a cell. The duration of the cell, which equals the duration of the data bit, is called a time interval. A logical 1 is represented by two transitions of the signal within a time interval, which corresponds to a cell with logical states 01 or 10. A logical 0 is represented by one transition within a time interval, which corresponds to a cell with logical states 00 or 11. In addition, the logical level at the start of a cell is inverted from the level at the end of the previous cell. [Figure 23-190](#) and [Table 23-576](#) show how data is encoded to the BMC format.

As shown in [Figure 23-190](#), the clock frequency is twice the unencoded data bit rate. In addition, the clock is always programmed to  $128 \times f_s$ , where  $f_s$  is the sample rate (see [Section 23.8.2.2.3.3, Frame Format](#), for details on how this clock rate is derived based on the S/PDIF format).

**Table 23-576. Biphase-Mark Encoder**

Data (Unencoded)	Previous State at Pin abe_mcasep_axr	BMC-Encoded Cell Output at abe_mcasep_axr
0	0	11
0	1	00
1	0	10
1	1	01

**23.8.2.2.3.2 Subframe Format**

Every audio sample transmitted in a subframe consists of 32 S/PDIF time intervals (or cells), numbered 0 to 31. [Figure 23-191](#) shows a subframe.

- Time intervals 0–3 carry one of the three permitted preambles to signify the type of audio sample in the current subframe. The preamble is not encoded in BMC format, and therefore the preamble code can contain more than two consecutive 0 or 1 logical states in a row. See [Table 23-577](#).
- Time intervals 4–27 carry the audio sample word in linear 2s-complement representation. The MSB is carried by time interval 27. When a 24-bit coding range is used, the LSB is in time interval 4. When a 20-bit coding range is used, time intervals 8–27 carry the audio sample word with the LSB in time interval 8. Time intervals 4–7 may be used for other applications and are designated auxiliary sample bits.
- If the source provides fewer bits than the interface allows (20 or 24), the unused LSBs are set to logical 0. For a nonlinear PCM audio application or a data application, the main data field can carry any other information.
- Time interval 28 carries the validity bit (V) associated with the main data field in the subframe.
- Time interval 29 carries the user data channel (U) associated with the main data field in the subframe.
- Time interval 30 carries the channel status information (C) associated with the main data field in the subframe. The channel status indicates if the data in the subframe is digital audio or some other type of data.
- Time interval 31 carries a parity bit (P) such that time intervals 4–31 carry an even number of 1s and an even number of 0s (even parity). As listed in [Table 23-577](#), the preambles (time intervals 0–3) are also defined with even parity.

**Figure 23-191. S/PDIF Subframe Format**

As listed in [Table 23-577](#), the McASP DIT generates only one polarity of preambles, and it assumes the previous logical state is 0. This is because the McASP assures an even-polarity encoding scheme when transmitting in DIT mode. If an underrun condition occurs, the DIT resynchronizes to the correct logic level on the `abe_mcasp_axr` pin before continuing with the next transmission.

**Table 23-577. Preamble Codes**

Preamble Code <sup>(1)</sup>	Previous Logical State	Logical States on pin <code>abe_mcasp_axr</code> <sup>(2)</sup>	Description
B (or Z)	0	1110 1000	Start of a block and subframe 1
M (or X)	0	1110 0010	Subframe 1
W (or Y)	0	1110 0100	Subframe 2

<sup>(1)</sup> Historically, preamble codes are referred to as B, M, and W. For use in professional applications, preambles are referred to as Z, X, and Y, respectively.

<sup>(2)</sup> The preamble is not BMC-encoded. Each logical state is synchronized to the serial clock. These eight logical states make up time slots (cells) 0 to 3 in the S/PDIF stream.

### 23.8.2.2.3.3 Frame Format

An S/PDIF frame is composed of two subframes (see [Figure 23-192](#)). For linear coded audio applications, the rate of frame transmission normally corresponds exactly to the source sampling frequency  $f_s$ . The S/PDIF format clock rate is therefore  $128 \times f_s$  ( $128 = 32$  cells per subframe  $\times 2$  clocks per cell  $\times 2$  subframes per sample). For example, for an S/PDIF stream at a 192-kHz sampling frequency, the serial clock is  $128 \times 192$  kHz = 24.58 MHz.

In 2-channel operation mode, the samples taken from both channels are transmitted by time multiplexing in consecutive subframes. Both subframes contain valid data (cell 28 validity bits for A- and B-channels, both set to 0).. The first subframe (left or A channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble M. However, the preamble of the first subframe changes to preamble B once every 192 frames to identify the start of the block structure used to organize the channel status information. The second subframe (right or B channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble W.

In single-channel operation mode in a professional application, the frame format is the same as in the 2-channel mode. Data is carried in the first subframe and may be duplicated in the second subframe. If the second subframe is not carrying duplicate data, cell 28 (validity bit) is set to logical 1.

**Figure 23-192. S/PDIF Frame Format**

### 23.8.3 McASP Integration

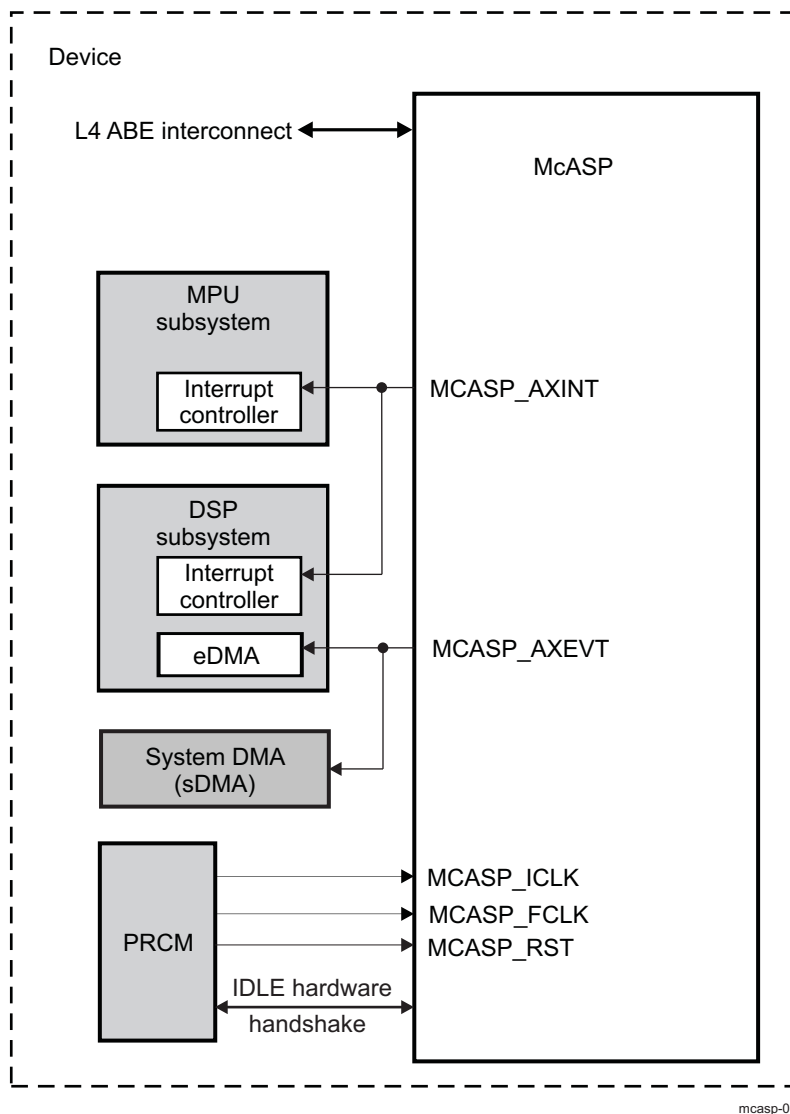

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

The McASP includes the following features:

- IDLE hardware handshake
- One DMA request
- One interrupt request (IRQ)

Figure 23-193 shows McASP integration.

Figure 23-193. McASP Integration

**NOTE:** For more information about the IDLE hardware handshake, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 23-578 through Table 23-580 summarize the integration of the module in the device.

**Table 23-578. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
McASP	PD_AUDIO	NO	L4_ABE

**Table 23-579. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
McASP	MCASP_ICLK	ABE_ICLK2	PRCM	McASP interface clock
	MCASP_FCLK	MCASP1_FCLK	PRCM	McASP functional clock
Resets				
McASP	MCASP_RST	AUDIO_RST	PRCM	AUDIO power domain reset

**Table 23-580. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
McASP	MCASP_AXINT	D_IRQ_92	DSP	McASP transmit interrupt
	MCASP_AXINT	MA_IRQ_109	Cortex™-A9	McASP transmit interrupt
DMA Requests				
McASP	MCASP_AXEVT	S_DMA_7	sDMA	McASP data transmit DMA request line to the system DMA (sDMA)
	MCASP_AXEVT	D_DMA_36	eDMA	McASP data transmit DMA request line to the DSP DMA (eDMA)

**NOTE:**

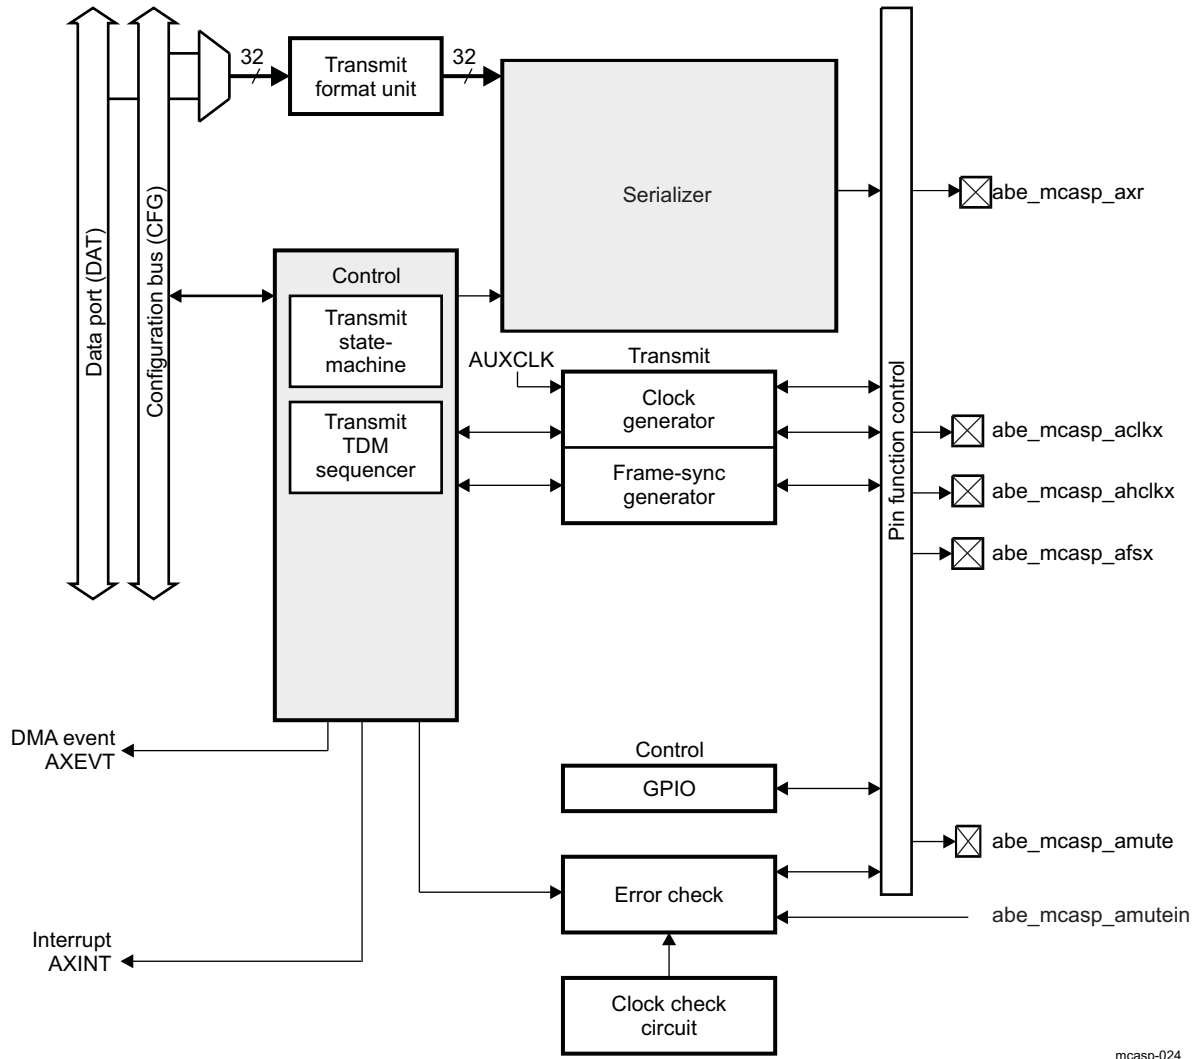

- For the description of the interrupt source, see [Section 23.8.4.11, Interrupt Requests](#).
- For the description of the DMA source, see [Section 23.8.4.12, DMA Requests](#).

### 23.8.4 McASP Functional Description

#### 23.8.4.1 Block Diagram

Figure 23-194 shows the major blocks of the McASP. The McASP has a transmit clock generator and a frame-sync generator, serializer, format unit, and error-checking logic.

Figure 23-194. McASP Block Diagram

mcasp-024

**NOTE:** The AUXCLK clock is sourced directly from MCASP\_FCLK.

#### 23.8.4.2 McASP Clock and Frame-Sync Configuration

The transmit serial clock (clock at the bit rate) can be sourced internally by passing through two clock dividers off the internal clock source (AUXCLK). The bit rate clock is generated internally and is driven out on the abe\_mcasp\_aclkx pin. An internally generated high-frequency clock can be driven out onto the abe\_mcasp\_ahclkx pin to serve as a reference clock for other components in the system.

### 23.8.4.2.1 Transmit Clock

The transmit bit clock, `abe_mcasp_aclkx`, is generated internally. For this purpose, the `MCASP_ACLKXCTL[5]` `CLKXM` bit must be set to 1. Thus, the clock is divided down by a programmable bit clock divider (the `MCASP_ACLKXCTL[4:0]` `CLKXDIV` bit field) from the source signal.

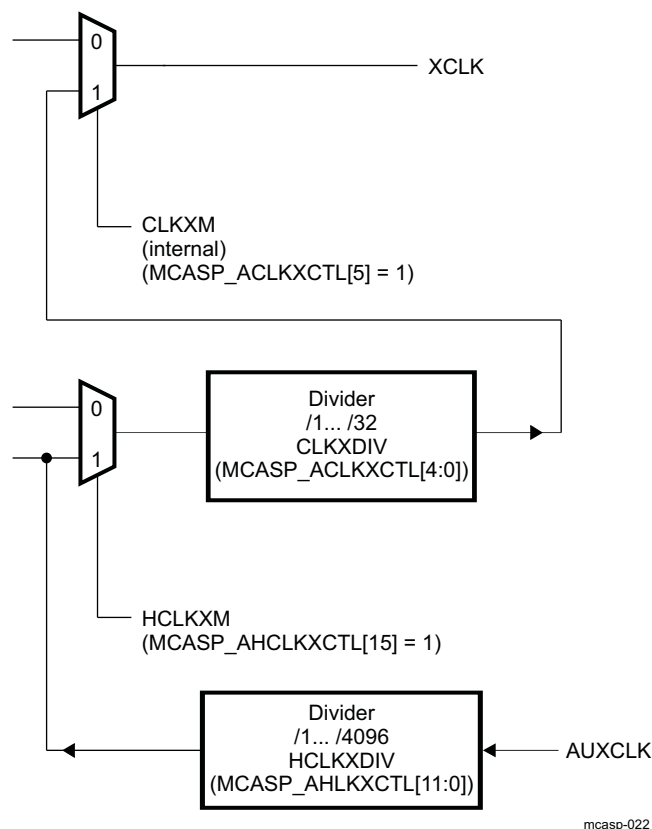

The transmit high-frequency master clock, `abe_mcasp_ahclkx`, is also generated internally. For this purpose, the `MCASP_AHCLKXCTL[15]` `HCLKXM` bit must be set to 1. Thus, the clock is divided down by a programmable high-clock divider (the `MCASP_AHCLKXCTL[11:0]` `HCLKXDIV` bit field) from the McASP internal clock source `AUXCLK`.

The transmit clock configuration is controlled by the following registers:

- `MCASP_ACLKXCTL`
- `MCASP_AHCLKXCTL`

Figure 23-195 is the block diagram of the transmit clock generator.

**Figure 23-195. Transmit Clock Generator Block Diagram**

### 23.8.4.2.2 Frame-Sync Generator

The transmit frame-sync pin is `abe_mcasp_afsx`. The frame-sync generator must be configured through the control register (`MCASP_TXFMCTL`) as:

- Internally generated `MCASP_TXFMCTL[1]` `FSXM` = 1
- Frame-sync polarity: Rising edge `MCASP_TXFMCTL[0]` `FSXP` = 0
- Frame-sync width: Single bit `MCASP_TXFMCTL[4]` `FXWID` = 0
- 384-slot, `MCASP_TXFMCTL[15:7]` `XMOD` = 1 1000 0000b

### 23.8.4.3 Serializers

The serializer shifts serial data out of the McASP. It consists of a shift register (XRSR), a data buffer (XBUF), a control register (MCASP\_XRSRCTL0), a serial data pin (abe\_mcasp\_axr), and logic to support the data alignment options of the McASP.

The serializer must be configured to transmit through the control register, thus shifting out data to abe\_mcasp\_axr. The serializer is clocked from the transmit section clock (abe\_mcasp\_aclkx) if configured to transmit. A serializer configured to transmit operates in lockstep.

Figure 23-196 is the serializer block diagram.

**Figure 23-196. Individual Serializer and Connections Within McASP**

For transmit, the microprocessor unit (MPU) services the McASP by writing data into the MCASP\_TXBUF0 register, which is an alias of the XBUF register for transmitting. The data automatically passes through the transmit format unit before reaching the XBUF register in the serializer. The data is then copied from XBUF to XRSR and shifted out from abe\_mcasp\_axr synchronously to the serial clock.

In addition to the data, the serializer shifts out other DIT-specific information accordingly (preamble, user data, etc.). The serializer configuration is controlled by MCASP\_XRSRCTL0[1:0] SRMOD = 0x1. Thus, the serializer is configured to operate in transmit mode.

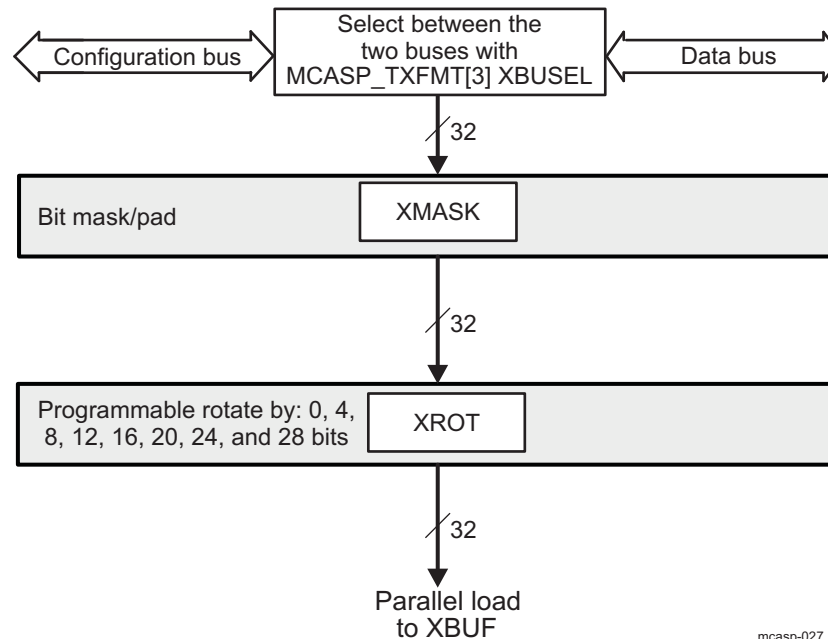

### 23.8.4.4 Format Unit

The McASP has one transmit formatting unit (TFU). This unit automatically remaps the data bits within the transmitted words between a natural format for the MPU (such as a Q31 representation) and the required format for the external serial device. During the remapping process, the format unit can also mask off certain bits.

This formatting unit consists of two stages:

- Bit mask (masks off bits)
- Rotate right (aligns data within word)

Figure 23-197 shows the transmit formatting unit.

**Figure 23-197. Transmit Format Unit**

mcasp-027

As shown in [Figure 23-197](#), the data to the transmit format unit can come from the configuration bus or the data bus. The selection is made through the [MCASP\\_TXFMT\[3\] XBUSEL](#) bit.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

In the transmit format unit (TFU), the input data bits are first masked-off with the [MCASP\\_TXMASK\[31:0\] XMASK](#) contents. The masked data is then right-rotated to [MCASP\\_TXFMT\[2:0\] XROT](#) positions, to produce the output word for a DIT transmission.

The bit mask stage includes a full 32-bit mask register, allowing selected individual bits to pass through the stage unchanged or be masked off.

While left-aligned Q31 data should be right-rotated by 4 positions, no right-rotation is required for right-aligned Q31 data. Because this is a rotation process, not a shifting process, bit 0 gets shifted back into bit 31 during the process.

The [MCASP\\_TXFMT\[17:16\] XDATLY](#) bit field must be set to a 0-bit delay (0x0 value).

For left-aligned Q31 data, the following transmit format unit settings process the data into right-aligned data, ready for transmission:

- [MCASP\\_TXFMT\[2:0\] XROT](#) = 0x2 (rotate right by 8 bits) - for 24-bit output audio data
- [MCASP\\_TXFMT\[2:0\] XROT](#) = 0x3 (rotate right by 12 bits) - for 20-bit output audio data
- [MCASP\\_TXFMT\[2:0\] XROT](#) = 0x4 (rotate right by 16 bits) - for 16-bit output audio data
- [MCASP\\_TXFMT\[15\] XRVRS](#) = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- [MCASP\\_TXMASK\[32\] XMASK](#) = 0xFFFFFFFF00 – 0xFFFF0000
- [MCASP\\_TXFMT\[14:13\] XPAD](#) = 0x0 (Pad extra bits with 0s.)

For right-aligned data, the following transmit format unit settings process the data into right-aligned audio data ready for transmission:

- [MCASP\\_TXFMT\[2:0\] XROT](#) = 0x0 (rotate right by 0 bits regardless of the audio word length)
- [MCASP\\_TXFMT\[15\] XRVRS](#) = 0x0 – Bit reversal is not enabled; the McASP naturally transmits and receives in an LSB-first order.
- [MCASP\\_TXMASK\[32\] XMASK](#) = 0x00FFFFFF – 0x0000FFFF

- **MCASP\_TXFMT**[14:13] XPAD = 0x0 (Pad extra bits with 0s.)

The example settings provided in [Table 23-581](#) should be applied to McASP in cases when Q31 data is transmitted as a 24-, 20- and 16-bit left- or right-aligned audio word, respectively. Note that the listed settings allow the McASP TFU to preserve the most significant bits and cut only the LSBs of the original Q31 MPU data.

**Table 23-581. McASP TFU Example Settings**

Output audio word alignment	Audio Word Length	Right-rotation (multiple of 4-bit positions)	XMASK	XROT
LEFT	16	16	0xFFFF0000	0x4
LEFT	20	12	0xFFFF000	0x3
LEFT	24	8	0xFFFFF00	0x2
RIGHT	16	0	0x000FFFFF	0
RIGHT	20	0	0x000FFFFF	0
RIGHT	24	0	0x00FFFFF	0

Assume the Q31 data word 0xFA5AFxxx (where x-marked nibbles of the data are applied as padding bits of the word) is generated by the MPU on the McASP CFG (peripheral) port. To transmit a left-aligned 20-bit version of the same word while preserving the MSBs in accordance with [Table 23-581](#), the user sets XMASK=0xFFFF000, and selects a right-rotation of 12 positions (XROT=0x3).

- After applying 0s (XPAD=0) as masking-off bits at the first TFU stage, the word is transformed to the word 0xFA5AF000.
- After a rotation by 12 positions to the right in TFU, the 20-bit output word obtained is 0x000FA5AF. The word gets ready for transmission being mapped with its LS-bit as bit 8 and its MS-bit as bit 27 within a S/PDIF bitstream. This word is shifted in a LSB-to-MSB order (XRVRS = 0x0) out of the XRSR register during a DIT transmission.

Assume that a right-aligned Q31 data word 0x yyyyE4B4 is generated by the MPU on the McASP CFG (peripheral) port (with the presumption that y-marked nibbles of the input data are applied as padding bits). To transmit a right-aligned 16-bit version of same word while preserving the MSBs in accordance with [Table 23-581](#), the user sets XMASK=0x0000FFFF, and selects right-rotation to 0 positions (XROT=0x0).

- After masking-off with 0s at first TFU stage, the word is transformed to 0x0000E4B4.
- Since no rotation is applied, the 16-bit output word obtained is actually the one obtained in the masking stage: 0x0000E4B4.

The examples use internal representation in integer and Q31 notation, but other fractional notations are also possible.

#### 23.8.4.5 Transmit State-Machine

The transmit state-machine controls the interactions between the various units in the transmit section. In addition, the state-machine keeps track of error conditions and serial port status. No serial transfers can occur until the transmit state-machine is released from reset.

The transmit state-machine is controlled by the transmit bitstream format register ([MCASP\\_TXFMT](#)) and it reports the McASP status and error conditions in the transmitter status register ([MCASP\\_TXSTAT](#)).

#### 23.8.4.6 Transmit TDM Sequencer

The time division multiplexing (TDM) sequencer is used to count the 384 subframes (slots) in the DIT block. If currently transmitting slot 1, slot 2 (next value of the TDM slot counter) should be used during the encode phase to select the appropriate C, V, and U bit, because the data encoded and written to the [MCASP\\_TXBUF0](#) register during the current time slot (slot 1) is actually shifted out on the next time slot.

The transmit TDM sequencer is controlled by the [MCASP\\_TXTDM](#) register and reports the current transmit slot to the [MCASP\\_TXTDMSLOT](#)[8:0] XSLOT CNT bit field.

### 23.8.4.7 McASP Software Reset

The McASP can be put into reset through the global transmit control register ([MCASP\\_GBLCTL](#)). A valid serial clock must be supplied to the McASP to assert the software reset bits in the [MCASP\\_GBLCTL](#) register.

### 23.8.4.8 McASP Power Management

[Table 23-582](#) describes power-management features available to the McASP.

**Table 23-582. Local Power-Management Features**

Feature	Registers	Description
Slave idle modes	<a href="#">MCASP_SYSCONFIG</a> [1:0] IDLE_MODE	Force-idle, no-idle, and smart-idle modes are available.

### 23.8.4.9 Transfer Modes

#### 23.8.4.9.1 DIT Transfer Mode

The DIT transfer mode of the McASP also supports transmission of audio data in S/PDIF, AES-3, and IEC-60958 formats. These formats are designed to carry audio data between different systems through an optical or coaxial cable. The DIT mode applies only to a serializer configured as transmitter, not receiver. For a description of the S/PDIF format, see [Section 23.8.2.2.3, S/PDIF Coding Format](#).

##### 23.8.4.9.1.1 Transmit DIT Encoding

When the McASP operates in DIT mode, the data transmitted is output as a biphasemark encoded bitstream, with preamble, channel status, user data, validity, and parity automatically stuffed into the bitstream by the McASP. The McASP includes separate validity bits for even/odd subframes and two 384-bit RAM modules to hold channel status and user data bits.

The transmit TDM time slot register ([MCASP\\_TXTDM](#)) should be programmed to all 1s during DIT mode. TDM functionality is not supported in DIT mode, except that the TDM slot counter counts the DIT subframes.

To transmit data in DIT mode, the following pins are typically required:

- `abe_mcasp_ahclkx` – transmit high-frequency master clock (The internal clock source can be used instead.)
- One serial data pin, `abe_mcasp_axr`, with serializer configured to transmit

The actual 24-bit audio data must always be in bit positions 23–0 after passing through the first three stages of the transmit format unit.

##### 23.8.4.9.1.2 Transmit DIT Clock and Frame-Sync Generation

The DIT transmitter works only in the following configuration:

- In the transmit frame control register ([MCASP\\_TXFMCTL](#)):
  - Internally generated transmit frame sync, `FSXM` = 1
  - Rising-edge frame sync, `FSXP` = 0
  - Bit-width frame sync, `FXWID` = 0
  - 384-slot TDM, `XMOD` = 1 1000 0000b
- In the transmit clock control register ([MCASP\\_ACLKXCTL](#)), `ASYNCR` = 1
- In the transmit bitstream format register ([MCASP\\_TXFMT](#)), `XSSZ` = 1111 (32-bit slot size)

All combinations of `abe_mcasp_ahclkx` and `abe_mcasp_aclkx` are supported.

The following summarizes the register configurations required for DIT mode. DIT mode-specific bit fields are in bold face:

- **MCASP\_PFUNC**: The data pin must be configured for McASP function. If `abe_mcasp_ahclkx` is used, it must also be configured for McASP function. Other pins can be configured to function as GPIOs, if desired.
- **MCASP\_PDIR**: The data pin must be configured as output. If internal clock source `AUXCLK` is used as the reference clock, it may be output on the `abe_mcasp_ahclkx` pin by configuring `abe_mcasp_ahclkx` as an output.
- **MCASP\_GBLCTL**: Global initialization
- **MCASP\_AMUTE**: Program all fields according to the mute control desired.
- **MCASP\_TXDITCTL**: The **DITEN** bit must be set to 1 to enable DIT mode. Configure other bits as desired.
- **MCASP\_TXMASK**: Mask the desired bits, depending upon left-aligned or right-aligned internal data.
- **MCASP\_TXFMT**: **XDATDLY** = 0. **XRVR** = 0. **XPAD** = 0. **XSSZ** = Fh (32-bit slot). **XBUSEL** = configured as desired. The **XROT** bit is configured either 0 or 8-bit rotate.
- **MCASP\_TXFMCTL**: Configure the bits according to former discussions.
- **MCASP\_ACLKXCTL**: **ASYN** = 1. Program the **CLKXDIV** bits to obtain the bit clock rate desired. **CLKXM** = 1.
- **MCASP\_AHCLKXCTL**: Program the **HCLKXDIV** bits to obtain the high-frequency bit clock rate desired.
- **MCASP\_TXTDM**: Set to FFFF FFFFh for all active slots for DIT transfers.
- **MCASP\_TXEVTCTL**: Program all fields according to the interrupts desired.
- **MCASP\_TXCLKCHK**: Program all fields according to the clock checking desired.
- **MCASP\_XRSRCTL0**: Set **SRMOD** = 1 (transmitter) for the DIT pins.
- **MCASP\_DITCSRAi** and **MCASP\_DITCSRBi**: Program the channel status bits as desired.
- **MCASP\_DITUDRAi** and **MCASP\_DITUDRBi**: Program the user data bits as desired.

### 23.8.4.9.1.3 DIT Channel Status and User Data Register Files

The channel status registers (**MCASP\_DITCSRAi** and **MCASP\_DITCSRBi**) and user data registers (**MCASP\_DITUDRAi** and **MCASP\_DITUDRBi**) are not double-buffered. Typically, programmers use one of the synchronizing interrupts, such as the last slot, to create an event at a safe time so the register may be updated. In addition, the MPU reads the transmit TDM slot counter to determine which word of the register is being used.

It is a software requirement to avoid writing to the word of user data and channel status that are being used to encode the current time slot; otherwise, it is undetermined whether old or new data is used to encode the bitstream.

The DIT subframe format is defined in [Section 23.8.2.2.3.2, Subframe Format](#). The channel status information (C) and user data (U) are defined in the following DIT control registers:

- **MCASP\_DITCSRA0** to **MCASP\_DITCSRA5**: The 192 bits in these six registers contain the channel status information for the left channel within each frame.
- **MCASP\_DITCSR0** to **MCASP\_DITCSR5**: The 192 bits in these six registers contain the channel status information for the right channel within each frame.
- **MCASP\_DITUDRA0** to **MCASP\_DITUDRA5**: The 192 bits in these six registers contain the user data information for the left channel within each frame.
- **MCASP\_DITUDRB0** to **MCASP\_DITUDRB5**: The 192 bits in these six registers contain the user data information for the right channel within each frame.
- The S/PDIF block format is shown in [Figure 23-192](#). There are 192 frames within a block (frame 0 to frame 191). There are two subframes within each frame (subframes 1 and 2 for the left and right channels, respectively).

The channel status and user data information sent on each subframe is summarized in [Table 23-583](#).

**Table 23-583. Channel Status and User Data for Each DIT Block**

Frame	Subframe	Preamble	Channel Status Defined in:	User Data Defined in:
<b>Defined by DITCSRA0, DITCSRB0, DITUDRA0, DITUDRB0</b>

### 23.8.4.10 Data Transmission

The MPU services the McASP by writing data to the [MCASP\\_TXBUF0](#) register for transmit operations. The McASP sets status flags and notifies the MPU whenever data is ready to be transmitted. [Section 23.8.4.10.1, Data Ready Status and Event/Interrupt Generation](#), discusses data-ready status in detail.

The [MCASP\\_TXBUF0](#) register can be accessed through one of the two peripheral ports of the device:

- Data port (DAT): This port is dedicated to DMA-initiated data transfers on the device.
- Configuration bus (CFG): This port is used for data transfers and peripheral configuration control on the device.

Section 23.8.4.10.1.2, *Transfers Through the Data Port (DAT)*, and Section 23.8.4.10.1.3, *Transfers Through the Configuration Bus (CFG)*, discuss how to perform transfers through the data port and the configuration port, respectively.

The MPU and DMA usages are discussed in Section 23.8.4.10.1.4, *Using the MPU for McASP Servicing*, and Section 23.8.4.10.1.5, *Using the DMA for McASP Servicing*, respectively.

### 23.8.4.10.1 Data Ready Status and Event/Interrupt Generation

#### 23.8.4.10.1.1 Transmit Data Ready

The transmit data ready flag XDATA bit in the `MCASP_TXSTAT` register reflects the status of the `MCASP_TXBUF0` register. The XDATA flag is set when data is transferred from the `MCASP_TXBUF0[n]` buffer to the `XRSR[n]` shift register, thus indicating that the `MCASP_TXBUF0` is empty and ready to accept new data from the MPU. This flag is cleared when the XDATA bit is written with 1, or when the serializer configured as transmitter is written by the MPU.

Whenever XDATA is set, the DMA AXEVT event is automatically generated to notify the DMA of the `MCASP_TXBUF0` empty status. An AXINTn interrupt is also generated if the XDATA interrupt is enabled in the `MCASP_EVTCTLX` register (for details, see Section 23.8.4.11.1, *Transmit Data Ready Interrupt*).

For DMA requests, the McASP does not require that `MCASP_TXSTAT` be read between DMA events. This means that, even if `MCASP_TXSTAT` already has the XDATA flag set to 1 from a previous request, the next transfer triggers another DMA request.

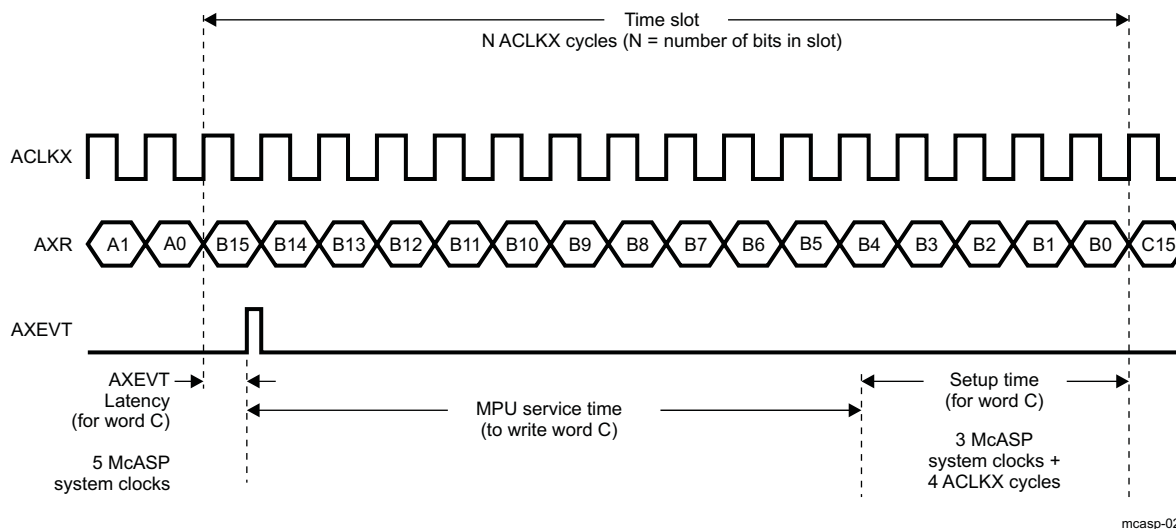

Because the serializer acts in lockstep, only one DMA event is generated to indicate that the transmit serializer is ready to be written to with new data.

Figure 23-198 shows the timing details of when AXEVT is generated at the McASP boundary. In this example, as soon as the last bit (A0) of word A is transmitted, the McASP sets the XDATA flag and generates an AXEVT event. However, it takes up to five McASP system clocks (AXEVT latency) before AXEVT is active at the McASP boundary. Upon AXEVT, the MPU can begin servicing the McASP by writing word C into the `MCASP_TXBUF0` (service time). The MPU must write word C into the `MCASP_TXBUF0` within the setup time required by the McASP (setup time).

The maximum service time (see Figure 23-198) can be calculated as:

$$\text{Service Time} = \text{Time Slot} - \text{AXEVT Latency} - \text{Setup Time}$$

Figure 23-198. MPU Service Time Upon Transmit DMA Event (AXEVT)

mcasp-020

### 23.8.4.10.1.2 Transfers Through the Data Port (DAT)

#### CAUTION

To perform internal transfers through the data port, clear the XBUSEL bit to 0 in the [MCASP\\_TXFMT](#) register. Failure to do so may result in software malfunction.

In a typical McASP transfer scenario, a DMA accesses the [MCASP\\_TXBUF0](#) through the data port (DAT). To access through the data port, simply have the DMA access [MCASP\\_TXBUF0](#) through its data port location.

---

**NOTE:** The DAT port allows the DMA to access only the transmit buffer [MCASP\\_TXBUF0](#) register. There is no way to access the McASP configuration registers within the DMA DAT port address ranges.

---

---

**NOTE:** To service the transmit serializer, the DMA must write to the [MCASP\\_TXBUF0](#) register using its L3 data port (DAT) address, while MPU/DSP must write to same register using its CFG (peripheral) port address. For more details about addressing [MCASP\\_TXBUF0](#) through CFG and DAT ports, see [Section 23.8.6.2.1, McASP Register Summary](#).

---

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition (see [Section 23.8.4.14.1, Buffer Underrun Error – Transmitter](#)).

### 23.8.4.10.1.3 Transfers Through the Configuration Bus (CFG)

#### CAUTION

To perform internal transfers through the configuration bus, set the XBUSEL bit to 1 in the [MCASP\\_TXFMT](#) register. Failure to do so may result in software malfunction.

In this method, the DMA/MPU accesses the [MCASP\\_TXBUF0](#) register through the configuration bus address.

When transmitting, the DMA/MPU must write data to the serializer and transmit within each time slot. Failure to do so may result in a buffer underrun condition ([Section 23.8.4.14.1, Buffer Underrun Error – Transmitter](#)).

### 23.8.4.10.1.4 Using the MPU for McASP Servicing

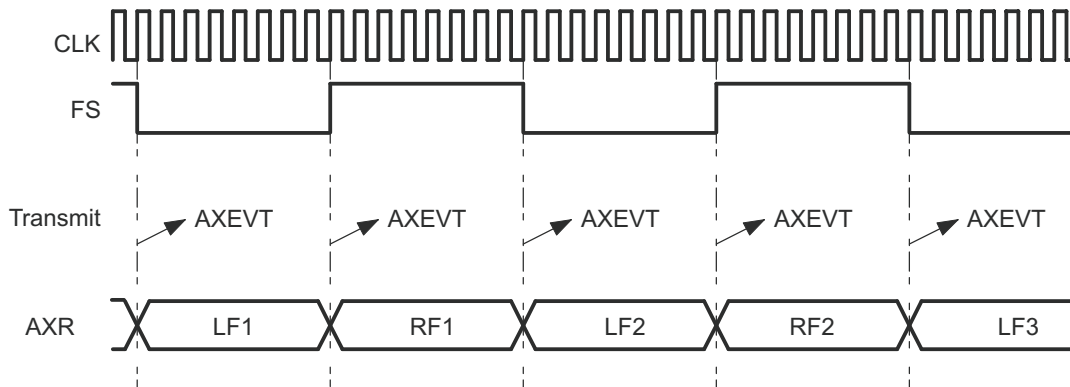

The MPU can be used to service the McASP through interrupts (upon [MCASP\\_AXINT](#) interrupt) or through polling the [XDATA](#) bit in the [MCASP\\_TXSTAT](#) register. As discussed in [Section 23.8.4.10.1.2, Transfers Through the Data Port \(DAT\)](#), and [Section 23.8.4.10.1.3, Transfers Through the Configuration Bus \(CFG\)](#), the MPU can access the McASP XBUF serializer buffer through the CFG port.

To use the MPU to service the McASP through interrupts, the [XSTAT](#) bit must be enabled in the [MCASP\\_TXEVTCTL](#) register to generate the [MCASP\\_AXINT](#) interrupt to the MPU upon data ready.

### 23.8.4.10.1.5 Using the DMA for McASP Servicing

The typical scenario is to use the DMA to service the McASP through the data port, although the DMA can also service the McASP through the configuration bus.

Figure 23-199. DMA Transmit Event in an Audio Example – One Event

mcasp-013

The DMA event AXEVT, which is triggered upon each XDATA transition from 0 to 1, is used to service the McASP transmit buffer (XBUF). Figure 23-199 is an example of an audio system with two audio channels (LF and RF) transmitted through the `abe_mcasp_axr` pin on the McASP. It shows the points at which event AXEVT is triggered.

The DMA AXEVT event is triggered on each time slot. In the example, AXEVT is triggered for each transmit audio channel time slot (time slot for channel LF, and time slot for channel RF). DMA events are generated automatically upon data ready, whereas MPU interrupt generation must be enabled in the `MCASP_EVTCTLX` register.

### 23.8.4.11 Interrupt Requests

Table 23-584 lists the event flags that can cause module interrupts.

Table 23-584. TX Events

Event Mask	Event Flag	Map to	Description
<code>MCASP_EVTCTLX[0] XUNDRN</code>	<code>MCASP_TXSTAT[0] XUNDRN</code>	<code>MCASP_AXINT</code>	Transmit underrun
<code>MCASP_EVTCTLX[1] XSYNCERR</code>	<code>MCASP_TXSTAT[1] XSYNCERR</code>	<code>MCASP_AXINT</code>	Unexpected transmit frame sync
<code>MCASP_EVTCTLX[2] XCKFAIL</code>	<code>MCASP_TXSTAT[2] XCKFAIL</code>	<code>MCASP_AXINT</code>	Transmit clock failure
<code>MCASP_EVTCTLX[4] XLAST</code>	<code>MCASP_TXSTAT[4] XLAST</code>	<code>MCASP_AXINT</code>	Transmit last slot interrupt
<code>MCASP_EVTCTLX[5] XDATA</code>	<code>MCASP_TXSTAT[5] XDATA</code>	<code>MCASP_AXINT</code>	Transmit data-ready interrupt
<code>MCASP_EVTCTLX[7] XSTAFRM</code>	<code>MCASP_TXSTAT[7] XSTAFRM</code>	<code>MCASP_AXINT</code>	Transmit start of frame interrupt

An interrupt line is asserted (active high) when one of these events occurs. Read the `MCASP_TXSTAT` register to determine which event occurs.

#### 23.8.4.11.1 Transmit Data Ready Interrupt

The transmit data-ready interrupt (XDATA) is generated if XDATA is 1 in the `MCASP_TXSTAT` register and XDATA is enabled in `MCASP_EVTCTLX`. Section 23.8.4.10.1, *Data Ready Status and Event/Interrupt Generation*, provides details on when XDATA is set in the `MCASP_TXSTAT` register.

A transmit-start-of-frame interrupt (XSTAFRM) is triggered by the recognition of a transmit frame sync.

A transmit-last-slot interrupt (XLAST) is a qualified version of the data-ready interrupt (XDATA). It has the same behavior as the data-ready interrupt, but is further qualified by having the data requested belonging to the last slot (the slot that just ended is the next-to-last TDM slot, the current slot is the last slot).

#### 23.8.4.11.2 Error Interrupt

Upon detection, the following error conditions generate interrupt flags:

In the transmit status register ([MCASP\\_TXSTAT](#)):

- Transmit underrun (XUNDRN)
- Transmit DMA error (XDMAERR)

Each interrupt source also has a corresponding enable bit in the transmit interrupt control register ([MCASP\\_EVTCTLX](#)). If the enable bit is set, an interrupt is requested when the interrupt flag is set in [MCASP\\_TXSTAT](#). If the enable bit is not set, no interrupt request is generated. However, the interrupt flag may be polled.

#### 23.8.4.12 DMA Requests

The McASP can generate one DMA request to the sDMA and eDMA controllers to transmit data ([MCASP\\_AXEVT](#)).

A DMA request to transmit data is generated if the XDATDMA bit in the [MCASP\\_TXEVTCTL](#) register is cleared.

#### 23.8.4.13 Audio Mute (AMUTE) Function

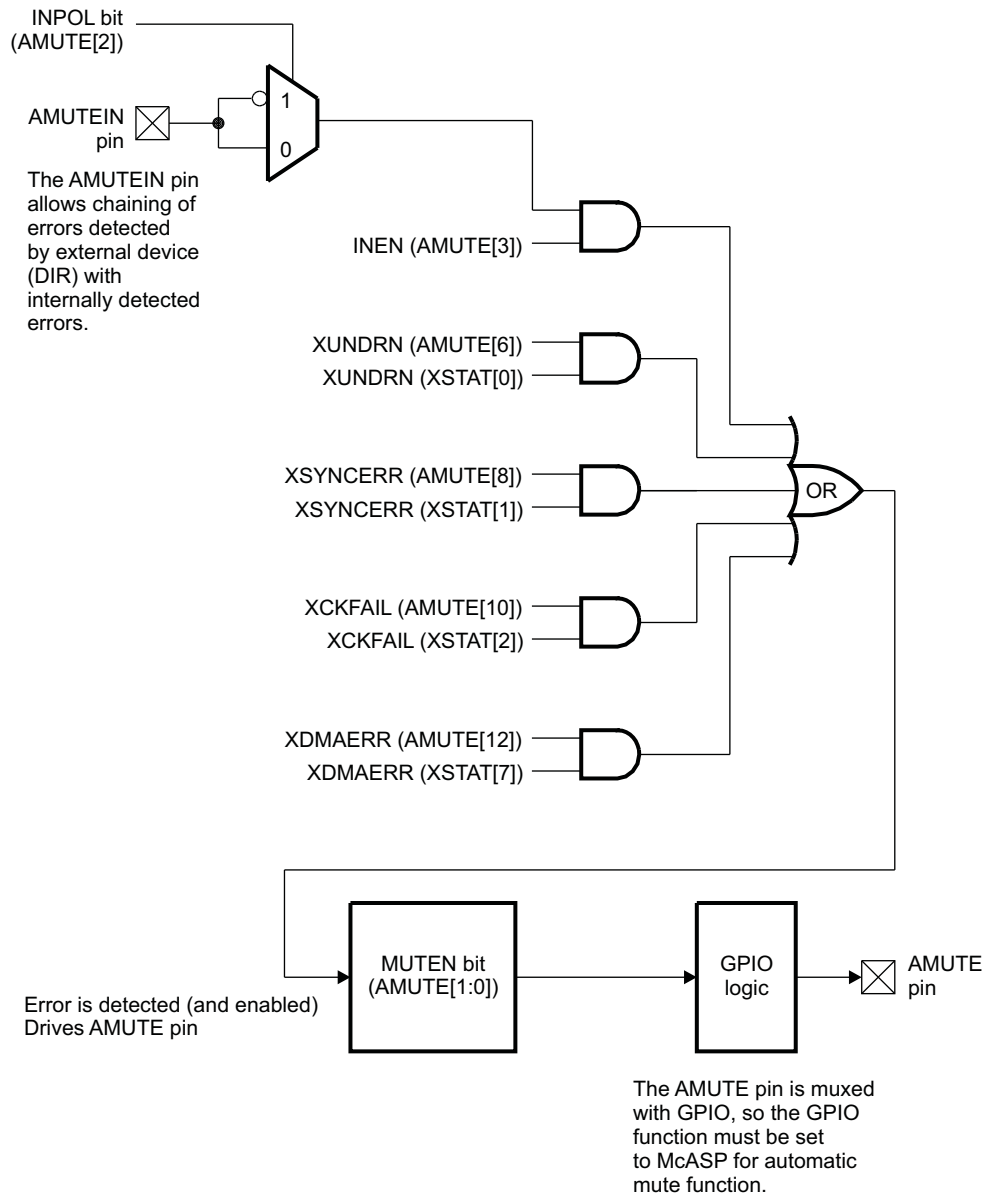

The McASP includes an automatic audio mute function (see [Figure 23-200](#)) that asserts, in hardware, the AMUTE pin to a preprogrammed output state, as selected by the MUTEN bit in the audio mute control register ([MCASP\\_AMUTE](#)). The AMUTE pin is asserted when one of the interrupt flags is set or an external device issues an error signal on the `abe_mcasp_amutein` input. Typically, the `abe_mcasp_amutein` input is shared with a device interrupt pin.

The `abe_mcasp_amutein` input allows the on-chip logic to consider a mute input from other devices in the system so that all errors may be considered. The `abe_mcasp_amutein` input has a programmable polarity to allow it to adapt to different devices, as selected by the INPOL bit in the [MCASP\\_AMUTE](#) register, and it must be explicitly enabled.

In addition to the external `abe_mcasp_amutein` input, the `abe_mcasp_amute` pin output may be asserted when one of the error interrupt flags is set and its mute function is enabled in the [MCASP\\_AMUTE](#) register.

When one or more errors are detected and enabled, the `abe_mcasp_amute` pin is driven to an active state that is selected by MUTEN in the [MCASP\\_AMUTE](#) register. The active polarity of the AMUTE pin is programmable by the MUTEN bit (the inactive polarity is the opposite of the active polarity). The `abe_mcasp_amute` pin remains driven active until software clears all the error interrupt flags that are enabled to mute, and until the `abe_mcasp_amutein` is inactive.

Figure 23-200. Audio Mute (AMUTE) Block Diagram

mcasp-017

### 23.8.4.14 Error Reporting

The McASP includes error-checking capability for the serial protocol and data underrun. In addition, the McASP includes a timer that continually measures the high-frequency master clock every 32 AHCLKX clock cycles. The value of the timer can be read to get a measurement of the clock frequency and has a minimum and maximum range setting that can set an error flag if the master clock goes out of a specified range.

When one or more errors (software selectable) are detected or the `abe_mcasp_amutein` input pin is asserted, the `abe_mcasp_amute` output pin may be asserted to a high or low level to immediately mute the audio output. In addition, an interrupt can be generated if desired, based on one or more error sources.

### 23.8.4.14.1 Buffer Underrun Error –Transmitter

A buffer underrun occurs when the serializer is instructed by the transmit state-machine to transfer data from `MCASP_TXBUF0` to XRSR, but `MCASP_TXBUF0` has not yet been written with new data since the last time the transfer occurred. When this occurs, the transmit state-machine sets the XUNDRN flag.

An underrun is checked only once per time slot. The `MCASP_TXSTAT[0]` XUNDRN flag is set when an underrun condition occurs. Once set, the XUNDRN flag remains set until the host explicitly writes 1 to the XUNDRN bit to clear it.

A pair of BMC zeros is shifted out when an underrun occurs (four bit times at 128 bfs). By shifting out a pair of zeros, a clock can be recovered on the receiver. To recover, reset the McASP and restart with the proper initialization.

### 23.8.4.14.2 DMA Error –Transmitter

A transmit DMA error, as indicated by the XDMAERR flag in the `MCASP_TXSTAT` register, occurs when the DMA writes more words to the data port of the McASP than it should.

XDMAERR indicates that the DMA wrote too many words to the McASP for a given transmit DMA event. Writing too few words results in a transmit underrun error setting XUNDRN in `MCASP_TXSTAT`.

While XDMAERR occurs infrequently, an occurrence indicates a serious loss of synchronization between the McASP and the DMA. The McASP transmitter and the DMA must be reinitialized to resynchronize them.

### 23.8.4.14.3 Clock Failure Detection

#### 23.8.4.14.3.1 Clock Failure Check Startup

It is initially expected of the clock failure circuits to generate an error until at least one measurement is taken. Therefore, the clock failure interrupts, clock switch, and mute functions should not be enabled immediately, but only after a specific startup procedure.

To start the transmit clock failure check procedure:

1. Configure the transmit clock failure detect logic (XMIN, XMAX, XPS) in the transmit clock check control register (`MCASP_TXCLKCHK`).
2. Clear the transmit clock failure flag (XCKFAIL) in the transmit status register (`MCASP_TXSTAT`).
3. Wait until the first measurement is taken (> 32 AHCLKX clock periods).
4. Verify that no clock failure is detected.
5. Repeat Step 2 through Step 4 until the clock is running and is no longer issuing clock failure errors.
6. After the transmit clock is measured and falls within the acceptable range, the following can be enabled:
  - (a) The transmit clock failure interrupt enable bit (XCKFAIL) in the transmitter interrupt control register (`MCASP_EVTCTLX`)
  - (b) The mute option (XCKFAIL) in the mute control register (`MCASP_AMUTE`)

#### 23.8.4.14.3.2 Transmit Clock Failure Check and Recovery

The transmit clock failure check circuit (see [Figure 23-201](#)) works off the internal McASP system clock and the external high-frequency serial clock (`abe_mcasps_ahclkx`). It continually counts the number of system clocks for every 32 high-rate serial clock (`abe_mcasps_ahclkx`) periods, and stores the count in XCNT of the transmit clock check control register (`MCASP_TXCLKCHK`) every 32 high-rate serial clock cycles.

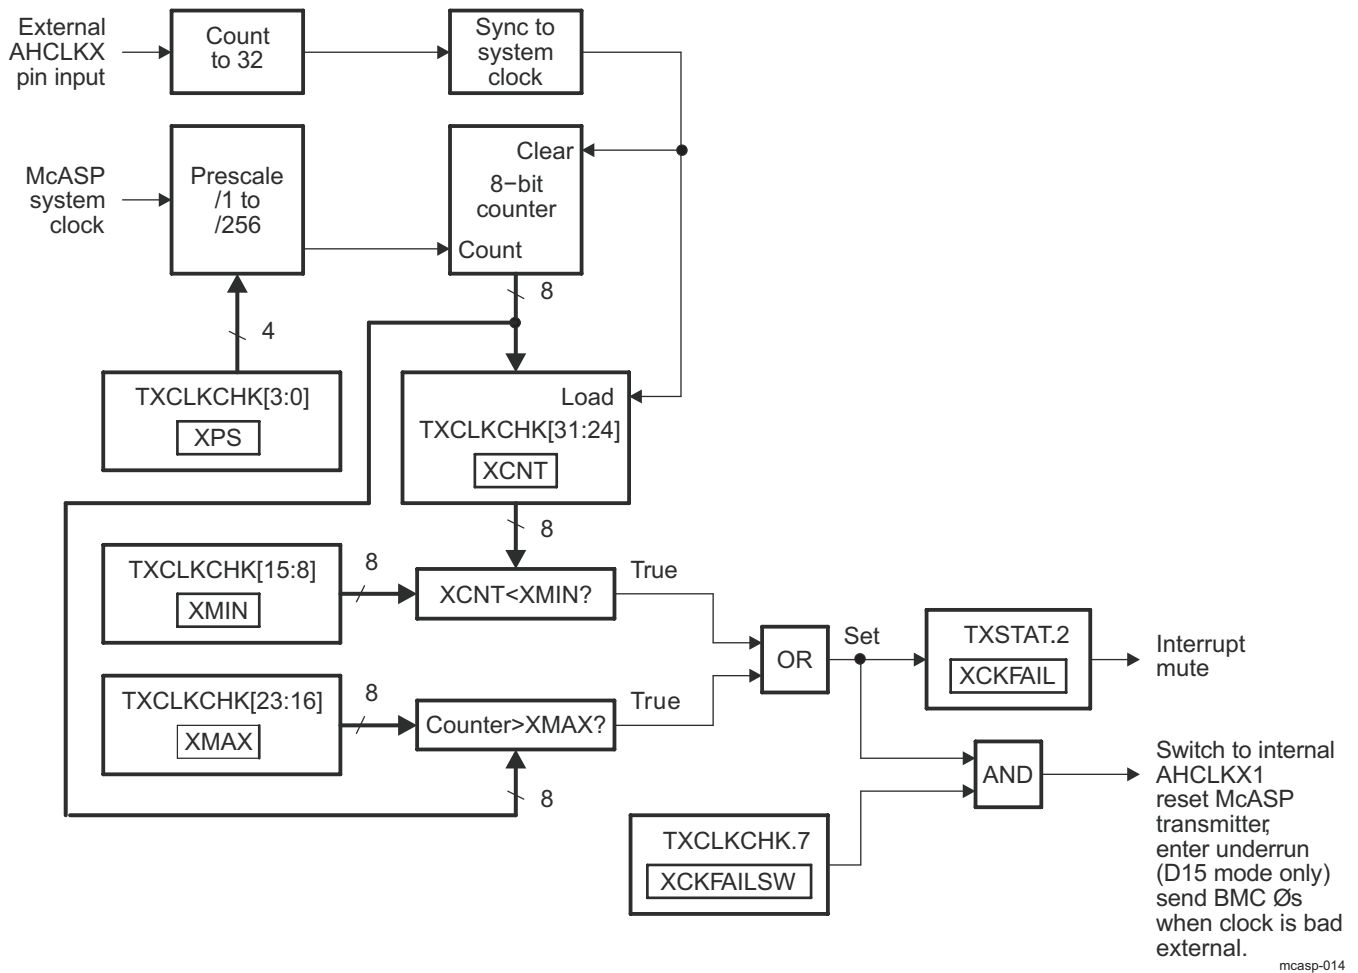

The logic compares the count against a user-defined minimum allowable boundary (XMIN), and automatically flags an interrupt (XCKFAIL in `MCASP_TXSTAT`) when an out-of-range condition occurs. An out-of-range minimum condition occurs when the count is less than XMIN. The logic continually compares the current count (from the running system clock counter) to the maximum allowable boundary (XMAX). This is so that if the external clock completely stops, the counter value is not copied to XCNT. An out-of-range maximum condition occurs when the count is greater than XMAX. The XMIN and XMAX fields are 8-bit unsigned values, and the comparison is performed using unsigned arithmetic.

An out-of-range count may indicate that an unstable clock was detected or that the audio source has changed and a new sample rate is being used.

For the transmit clock failure check circuit to operate correctly, the high-frequency serial clock divider must be taken out of reset.

If a clock failure is detected, the transmit clock failure flag (XCKFAIL) in `MCASP_TXSTAT` is set. This causes an interrupt if the transmit clock failure interrupt enable bit (XCKFAIL) in `MCASP_EVTCTLX` is set.

**Figure 23-201. Transmit Clock Failure Detection Circuit Block Diagram**

mcasp-014

## 23.8.5 McASP Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the McASP module.

### 23.8.5.1 Global Initialization

#### 23.8.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the McASP module is used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the McASP (for more information, see the [Section 23.8.3](#), *McASP Integration*, and [Section 23.8.2](#), *McASP Environment*).

[Table 23-585](#), describes the global initialization of surrounding modules.

**Table 23-585. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module functional and interface clocks must be enabled. (See <a href="#">Chapter 3</a> , <i>Power, Reset, and Clock Management</i> .)
Control module	Module-specific pad muxing and other pad configurations must be set in the control module. (See <a href="#">Chapter 18</a> , <i>Control Module</i> .)
(Optional) Cortex-A9 MPU INTC or DSP INTC	INTC configuration must be done to enable the interrupts from the McASP. (See <a href="#">Chapter 17</a> , <i>Interrupt Controllers</i> .)
(Optional) sDMA (or eDMA or aDMA)	DMA configuration must be done to enable the McASP DMA data channel requests.
(Optional) ABE_L4 and L3 Interconnects	For more information about the interconnect configuration, see <a href="#">Chapter 13</a> , <i>Interconnect</i> .

**NOTE:** The MPU/DSP INTC and the sDMA/eDMA/aDMA configurations are required when the interrupt and DMA-based communication modes are used.

#### 23.8.5.1.2 McASP Global Initialization

##### 23.8.5.1.2.1 Main Sequence – McASP Global Initialization

The procedure in [Table 23-586](#) initializes the McASP after a power-on reset (POR).

**Table 23-586. McASP Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Apply software reset to different McASP components.	MCASP_GBLCTL[12:8]	0x00
Poll the bits to ensure the active reset value (0x00) is successfully latched into the register.	MCASP_GBLCTL[12:8]	=0x00
Configure the local power management.	MCASP_SYSCONFIG[1:0] IDLE_MODE	0x-
Configure the transmit format unit.	See <a href="#">Section 23.8.5.1.2.2</a> .	
Configure the transmit frame sync generator.	See <a href="#">Section 23.8.5.1.2.3</a> .	
Configure the transmit clock generator.	See <a href="#">Section 23.8.5.1.2.4</a> .	
Configure the TDM sequencer—set all slots active.	MCASP_TXTDM[31:0] XTDMs	0xFFFF FFFF
Configure the serializer for transmit mode operation.	MCASP_XRSRCTL0[1:0] SRMOD	0x1
Configure the McASP pins functionality.	See <a href="#">Section 23.8.5.1.2.5</a> .	
Configure the McASP mute input/output conditions.	See <a href="#">Table 23-591</a> .	
Enable the McASP DIT-transmission mode.	MCASP_TXDITCTL[0] DITEN	0x1
Configure DIT-specific subframe fields.	See <a href="#">Table 23-592</a> .	

**Table 23-586. McASP Global Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Release from reset state the divider that outputs the <code>abe_mcasp_ahclkx</code> clock. <sup>(1)</sup>	<code>MCASP_GBLCTL[9]</code> XHCLKRST	0x1
Poll the bit to ensure that it is successfully latched in the register.	<code>MCASP_GBLCTL[9]</code> XHCLKRST	=0x1
Release from reset state the divider that outputs the <code>abe_mcasp_aclkx</code> clock. <sup>(1)</sup>	<code>MCASP_GBLCTL[8]</code> XCLKRST	0x1
Poll the bit to ensure that it is successfully latched in the register.	<code>MCASP_GBLCTL[8]</code> XCLKRST	=0x1

<sup>(1)</sup> During reset state the local McASP internal clock dividers maintain a 1:1 ratio at their outputs. The values stored in the `MCASP_AHCLKX` and `MCASP_ACLKX` registers are ignored; hence, the transmission clock does not stop during the reset state of the dividers.

### 23.8.5.1.2.2 Subsequence – Transmit Format Unit Configuration

The procedure in [Table 23-587](#) configures the transmit frame format unit of the McASP module.

**NOTE:**

- The first transmit data bit always has a 0-bit delay.
- The bitstream is always transmitted in least-significant-bit (LSB)-first order.
- Pad value for extra bits in a certain slot is always 0.

**Table 23-587. Transmit Format Unit Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure the slot size to 32 bits.	<code>MCASP_TXFMT[7:4]</code> XSSZ	0xF
<b>IF:</b> the MPU or DMA data to transmit is left- aligned	Software test condition	
Set data mask in the range 0xFFFF FF00 – 0xFFFF 0000.	<code>MCASP_TXMASK[31:0]</code> XMASK	0x- <sup>(1)</sup>
Rotate data right by a multiple-of-4 bit positions.	<code>MCASP_TXFMT[2:0]</code> XROT	0x- <sup>(1)</sup>
<b>ELSE</b>		
Set data mask in the range 0x00FF FFFF– 0x0000 FFFF.	<code>MCASP_TXMASK[31:0]</code> XMASK	0x- <sup>(1)</sup>
Rotate data right by 0-bit positions.	<code>MCASP_TXFMT[2:0]</code> XROT	0x0
<b>ENDIF</b>		

<sup>(1)</sup> See [Section 23.8.4.4, Format Unit](#).

### 23.8.5.1.2.3 Subsequence – Transmit Frame Synchronization Generator Configuration

The procedure in [Table 23-588](#) configures the transmit frame synchronization generator of the McASP module.

**NOTE:** The frame synchronization signal is always rising-edge active and always has a single-bit width.

**Table 23-588. Transmit Frame-Synchronization Generator Configuration**

Step	Register/Bit Field/Programming Model	Value
Select 384-slot size block.	<code>MCASP_TXFMCTL[15:7]</code> XMOD	0x180
Select internally-generated transmit frame sync.	<code>MCASP_TXFMCTL[1]</code> FSXM	0x1

### 23.8.5.1.2.4 Subsequence – Transmit Clock Generator Configuration

**NOTE:** By default, the ACLKX and AHCLKX clocks are generated only from the McASP internal clock source.

The procedure in [Table 23-589](#) configures the transmit clock generator of the McASP module.

**Table 23-589. Transmit Clock Generator Configuration**

Step	Register/Bit Field/Programming Model	Value
Set the divisor for the internally generated high frequency clock– <code>abe_mcasp_ahclkx</code> .	<code>MCASP_AHCLKXCTL[11:0]</code> HCLKXDIV	0x-
Set the divisor for the internally generated transmission clock– <code>abe_mcasp_aclkx</code> .	<code>MCASP_ACLKXCTL[4:0]</code> CLKXDIV	0x-
Configure the transmit clock failure detect logic.	See <a href="#">Section 23.8.4.14.3.1</a> , <i>Clock Failure Check Startup</i> .	

### 23.8.5.1.2.5 Subsequence—McASP Pins Functional Configuration

The procedure in [Table 23-590](#) configures the McASP pins for McASP functionality.

**Table 23-590. McASP Pins Functional Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure module different pins to have McASP functionality.	<code>MCASP_PFUNC[31:0]</code>	0x0
Configure the McASP pins as outputs: <code>abe_mcasp_afsx</code> <code>abe_mcasp_ahclkx</code> <code>abe_mcasp_aclkx</code> <code>abe_mcasp_amute</code> <code>abe_mcasp_axr</code>	<code>MCASP_PDIR[28]</code> AFSX; <code>MCASP_PDIR[27]</code> AHCLKX; <code>MCASP_PDIR[26]</code> ACLKX; <code>MCASP_PDIR[25]</code> AMUTE; <code>MCASP_PDIR[0]</code> AXR0;	0x1 0x1 0x1 0x1 0x1

### 23.8.5.1.2.6 Subsequence – McASP Mute Input/Output Trigger Condition Settings

The procedure in [Table 23-591](#) configures the behavior of the mute associated I/Os and different trigger conditions for the McASP mute output functionality.

**Table 23-591. McASP Mute Input/Output Trigger Condition Settings**

Step	Register/Bit Field/Programming Model	Value
Optional: Select to drive AMUTE active enable bit on transmit DMA error.	<code>MCASP_AMUTE[12]</code> XDMAERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit clock failure.	<code>MCASP_AMUTE[10]</code> XCKFAIL	0x1
Optional: Select to drive AMUTE active enable bit on transmit frame synchronization error.	<code>MCASP_AMUTE[8]</code> XSYNCERR	0x1
Optional: Select to drive AMUTE active enable bit on transmit underrun error.	<code>MCASP_AMUTE[6]</code> XUNDRN	0x1
Optional: Enable sensitivity of the <code>abe_mcasp_amute</code> output to <code>abe_mcasp_amutein</code> error source.	<code>MCASP_AMUTE[3]</code> INEN	0x1
Optional: Select the <code>abe_mcasp_amutein</code> input polarity.	<code>MCASP_AMUTE[2]</code> INPOL	0x1
Optional: Configure the behavior of the <code>abe_mcasp_amute</code> output.	<code>MCASP_AMUTE[1:0]</code> MUTEN	0x1

**23.8.5.1.2.7 Subsequence – DIT-Specific Subframe Fields Configuration**

**NOTE:** The McASP integrated in the device supports only the DIT transmission mode that uses the S/PDIF protocol.

The procedure in [Table 23-592](#) configures the DIT-specific subframe fields as part of the S/PDIF format data.

**Table 23-592. DIT-Specific Subframe Fields Configuration**

Step	Register/Bit Field/Programming Model	Value
Configure the valid bit value for odd time slots.	MCASP_TXDITCTL[3] VB	0x-
Configure the valid bit value for even time slots.	MCASP_TXDITCTL[2] VA	0x-
Configure the user data bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITUDRAi[31:0] DITUDRAi, where i = 0 to 5	0x-
	MCASP_DITUDRBi[31:0] DITUDRBi, where i= 0 to 5	0x-
Configure the channel status bit for each subframe A and B in a 384-slot S/PDIF block.	MCASP_DITCSRAi[31:0] , where i = 0 to 5	0x-
	MCASP_DITCSRBi[31:0] , where i = 0 to 5	0x-

**23.8.5.2 Operational Modes Configuration**

**23.8.5.2.1 McASP DIT Transmission Mode**

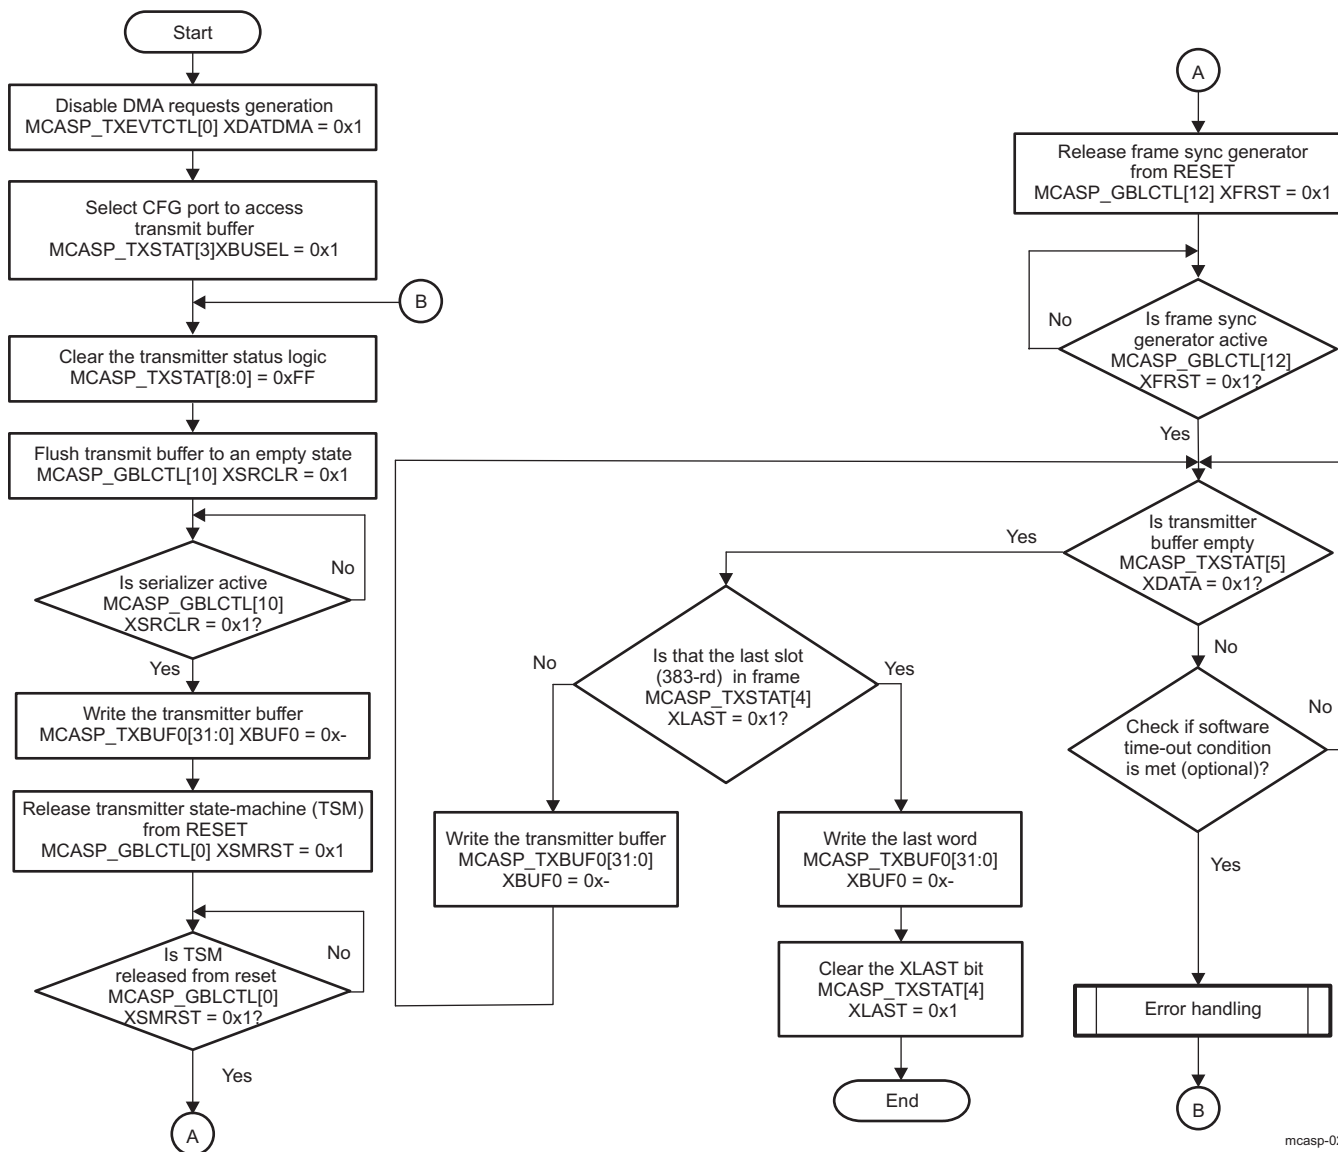

**23.8.5.2.1.1 Main Sequence – McASP DIT Polling Transmission Method**

[Figure 23-202](#) shows the McASP DIT polling method.

**NOTE:**

- The McASP polling transmission model considers the MPU/DSP as the source of audio data for the McASP transmission buffer.
- The DMA request is disabled and the XDMAERR event is not analyzed.
- The flow chart shown in [Figure 23-202](#) shows the sequence for transmitting one DIT frame.

**Figure 23-202. McASP DIT Transmission Polling Method**

mcasp-028

Table 23-593 summarizes the register call for the polling mode.

**Table 23-593. Register Call Summary for Main Sequence – McASP DIT Transmission Polling Method**

Register Name	Register Name	Register Name	Register Name	Register Name
MCASP_TXSTAT	MCASP_GBLCTL	MCASP_TXBUF0	MCASP_TXFMT	MCASP_TXEVTCTL

Register Name	Register Name
MCASP_GBLCTL	MCASP_TXBUFO

### 23.8.5.2.1.3 Main Sequence –McASP DIT DMA Transmission Method

[Table 23-597](#) shows the configuration of the McASP using the DMA method for transmission. Possible interrupt error event servicing is also considered. [Table 23-596](#) shows the initial setup for DMA-based transmission.

**NOTE:** Because of the DATA port burst access capability with the DMA method, It is preferable for transfers to be initiated through the DATA port rather than through the CFG port.

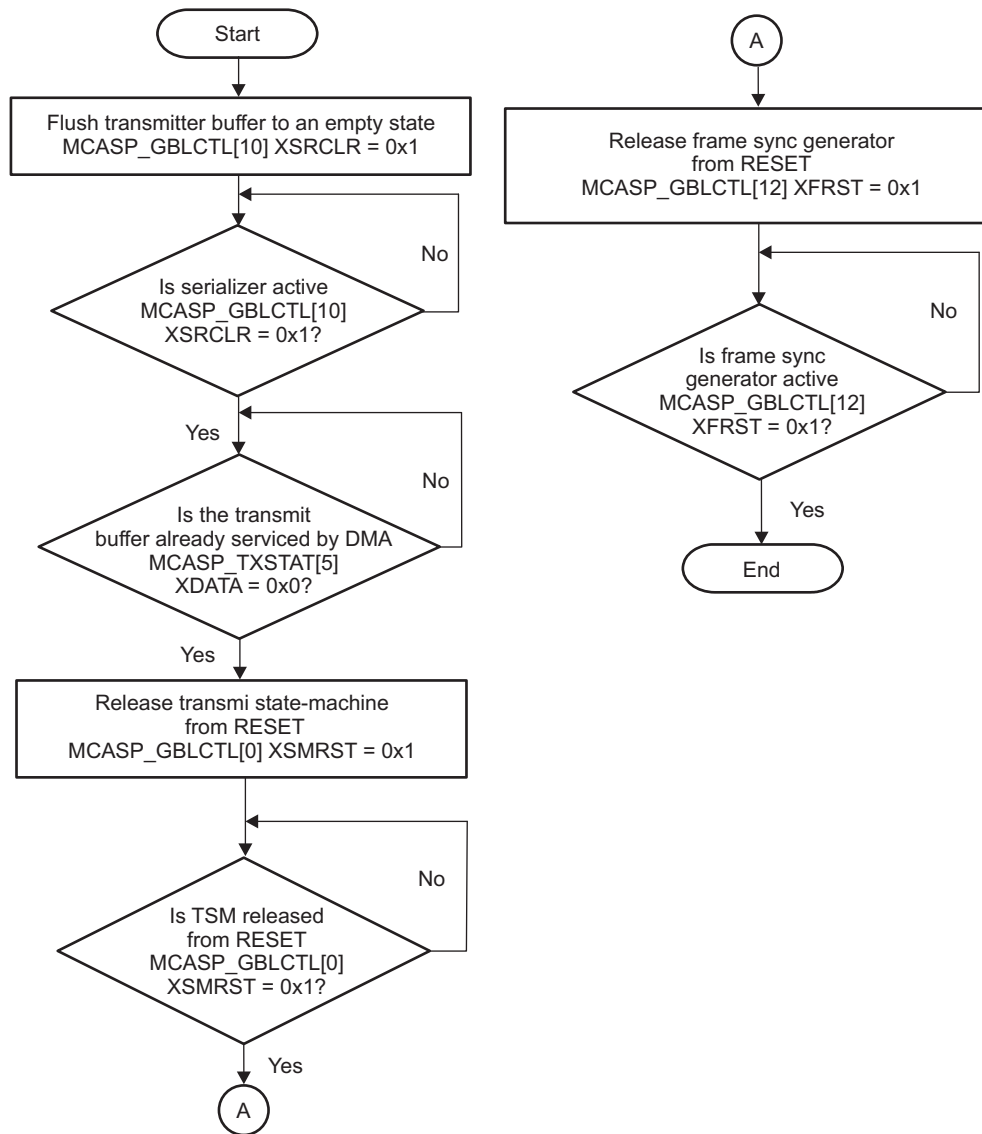

**Table 23-597. McASP DMA Transmission Model with Interrupt Events Servicing**

Step	Register/Bit Field/Programming Model	Value
Select DATA port to access the transmit buffer.	MCASP_TXFMT[3] XBUSEL	0x0
Enable the DMA requests generation.	MCASP_TXEVTCTL[0] XDATDMA	0x0
Clear the transmitter status logic.	MCASP_TXSTAT[8:0]	0xFF
Enable the DMA error event.	MCASP_EVTCTLX[7] XDMAERR	0x1
Optional: Enable the transmit error event interrupts.	MCASP_EVTCTLX[2] XCKFAIL MCASP_EVTCTLX[1] XSYNCERR MCASP_EVTCTLX[0] XUNDRN	0x1 0x1 0x1
Optional: Enable the start of frame interrupt. Optional: Enable the last slot data interrupt.	MCASP_EVTCTLX [7] XSTAFRM MCASP_EVTCTLX[4] XLAST	0x1 0x1
Disable the data ready event transmit interrupt.	MCASP_EVTCTLX[5] XDATA	0x0
DMA transmission procedure	See <a href="#">Section 23.8.5.2.1.4</a> .

**Table 23-612. MCASP\_PDOUT**

<b>Address Offset</b>	0x0000 0018
<b>Physical Address</b>	0x4902 8018 0x4012 8018 0x01D2 8018
<b>Description</b>	<p>Pin data output register - holds a value for data out at all times, and may be read back at all times. The value held by <b>MCASP_PDOUT</b> is not affected by writing to <b>MCASP_PDIR</b> and <b>MCASP_PFUNC</b>. However, the data value in <b>MCASP_PDOUT</b> is driven out onto the McASP pin only if the corresponding bit in <b>MCASP_PFUNC</b> is set to 1 (GPIO function) and the corresponding bit in <b>MCASP_PDIR</b> is set to 1 (output).</p> <p>When reading data, it returns the corresponding bit value in <b>MCASP_PDOUT</b>[n]; it does not return the input from the I/O pin.</p> <p>When writing data, writes to the corresponding <b>MCASP_PDOUT</b>[n] bit.</p> <p>PDOUT has these aliases or alternate addresses:</p> <ul style="list-style-type: none"> <li><b>MCASP_PDSET</b> - when written to at this address, writing a 1 to a bit in <b>MCASP_PDSET</b> sets the corresponding bit in <b>MCASP_PDOUT</b> to 1; writing a 0 has no effect and keeps the bits in <b>MCASP_PDOUT</b> unchanged.</li> <li><b>MCASP_PDCLR</b> - when written to at this address, writing a 1 to a bit in <b>MCASP_PDCLR</b> clears the corresponding bit in <b>MCASP_PDOUT</b> to 0; writing a 0 has no effect and keeps the bits in <b>MCASP_PDOUT</b> unchanged.</li> </ul> <p>There is only one set of data-out bits, <b>MCASP_PDOUT</b>[31:0]. The other registers, <b>MCASP_PDSET</b> and <b>MCASP_PDCLR</b>, are just different addresses for the same control bits, with different behaviors during writes.</p>
<b>Type</b>	RW

<b>Description</b>	Global transmit control register - provides initialization of the transmit section. The bit fields in <a href="#">MCASP_GBLCTL</a> are synchronized and latched by the <code>abe_mcasps_aclx</code> clock. Before programming <a href="#">MCASP_GBLCTL</a> , ensure that the serial clocks are running. If the corresponding external serial clock, <code>abe_mcasps_clkx</code> , is not yet running, select the internal serial clock source in <code>AHCLKXCTL</code> and <code>ACLKXCTL</code> before programming <a href="#">MCASP_GBLCTL</a> . Also, after programming any bits in <a href="#">MCASP_GBLCTL</a> , do not proceed until reading back from <a href="#">MCASP_GBLCTL</a> and verifying that the bits in <a href="#">MCASP_GBLCTL</a> are latched.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																			XFRST	XSMRST	XSRCLR	XHCLKRST	XCLKRST	RESERVED								

Bits	Field Name	Description	Type	Reset
31:13	RESERVED	Reserved	RW	0x00000
12	XFRST	Transmit frame-sync generator reset enable bit 0x0: The transmit frame-sync generator is reset. 0x1: The transmit frame-sync generator is active. When released from reset, the transmit frame-sync generator begins counting serial clocks and generating frame sync as programmed.	RW	0
11	XSMRST	Transmit state-machine reset enable bit 0x0: The transmit state-machine is held in reset. <code>abe_mcasps_axr</code> pin state: If <a href="#">MCASP_PFUNC</a> [0] = 0 and <a href="#">MCASP_PDIR</a> [0] = 1, the serializer drives the <code>abe_mcasps_axr</code> pin to the state specified for inactive time slot 0x1: The transmit state-machine is released from reset. When released from reset, the transmit state-machine immediately transfers data from <code>XBUF[n]</code> to <code>XRSR[n]</code> . The transmit state-machine sets the underrun flag ( <code>XUNDRN</code> ) in <a href="#">MCASP_TXSTAT</a> , if <code>XBUF[n]</code> have not been preloaded with data before reset is released. The transmit state-machine also immediately begins detecting frame sync and is ready to transmit. Transmission of TDM time slot begins at slot 0 after reset is released.	RW	0
10	XSRCLR	Transmit serializer clear enable bit. By clearing and then setting this bit, the transmit buffer is flushed to an empty state ( <code>XDATA = 1</code> ). If <code>XSMRST = 1</code> , <code>XSRCLR = 1</code> , <code>XDATA = 1</code> , and <code>XBUF</code> is not loaded with new data before the start of the next active time slot, an underrun occurs. 0x0: The transmit serializer is cleared. 0x1: The transmit serializer is active. When the transmit serializer is first taken out of reset ( <code>XSRCLR</code> changes from 0 to 1), the transmit data ready bit ( <code>XDATA</code> ) in <a href="#">MCASP_TXSTAT</a> is set to indicate <code>XBUF</code> is ready to be written.	RW	0
9	XHCLKRST	Transmit high-frequency clock divider reset enable bit 0x0: The transmitter high-frequency clock divider is held in reset. 0x1: The transmitter high-frequency clock divider is running.	RW	0
8	XCLKRST	Transmit clock divider reset enable bit 0x0: The transmit clock divider is held in reset. When the clock divider is in reset, it passes through a divide-by-1 of its input. 0x1: The transmit clock divider is running.	RW	0
7:0	RESERVED	Reserved	RW	0x0

**Table 23-640. MCASP\_TXSTAT**

<b>Address Offset</b>	0x0000 00C0	<b>Instance</b>	MCASP_L3 MCASP_CORTEX-A9 MCASP_DSP
<b>Physical Address</b>	0x4902 80C0 0x4012 80C0 0x01D2 80C0		
<b>Description</b>	Transmitter status register - If the McASP logic attempts to set an interrupt flag in the same cycle that the CPU writes to the flag to clear it, the McASP logic has priority and the flag remains set. This also causes the generation of a new interrupt request.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																XERR	XDMAERR	XSTAFRM	XDATA	XLAST	XTDMSLOT	XCKFAIL	XSYNCERR	XUNDRN							

Bits	Field Name	Description	Type	Reset
31:9	RESERVED	Reserved	RW	0x000000
8	XERR	XERR bit always returns a logic-OR of: XUNDRN   XSYNCERR   XCKFAIL   XDMAERR. Allows a single bit to be checked to determine if a transmitter error interrupt has occurred.  0x0: No errors have occurred. 0x1: An error has occurred.	RW	0
7	XDMAERR	Transmit DMA error flag. XDMAERR is set when the CPU or DMA writes more words to the data port of the McASPin a given time slot than it should. Causes a transmit interrupt (XINT) if this bit and XDMAERR in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Transmit DMA error did not occur. 0x1: Transmit DMA error occurred.	RW	0
6	XSTAFRM	Transmit start of frame flag. Causes a transmit interrupt (XINT) if this bit and XSTAFRM in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: No new transmit frame sync (AFSX) is detected. 0x1: A new transmit frame sync (AFSX) is detected.	RW	0
5	XDATA	Transmit data ready flag. Causes a transmit interrupt (XINT) if this bit and XDATA in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect  0x0: XBUF is written and is full  0x1: Data is copied from XBUF to XRSR. XBUF is empty and ready to be written. XDATA is also set when the transmit serializers are taken out of reset. When XDATA is set, it always causes a DMA event (AXEVT).	RW	0

Bits	Field Name	Description	Type	Reset
4	XLAST	Transmit last slot flag. XLAST, along with XDATA, are set if the current slot is the last slot in a frame. Causes a transmit interrupt (XINT) if this bit and XLAST in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Current slot is not the last slot in a frame. 0x1: Current slot is the last slot in a frame. XDATA is also set.	RW	0
3	XTDMSLOT	Returns the LSB of XSLOT. Allows a single read of XSTAT to determine whether the current TDM time slot is even or odd.  read 0x0: Current TDM time slot is odd. read 0x1: Current TDM time slot is even.	R	0
2	XCKFAIL	Transmit clock failure flag. XCKFAIL is set when the transmit clock failure detection circuit reports an error. Causes a transmit interrupt (XINT) if this bit and XCKFAIL in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Transmit clock failure did not occur. 0x1: Transmit clock failure occurred	RW	0
1	XSYNCERR	Unexpected transmit frame-sync flag. XSYNCERR is set when a new transmit frame sync (AFSX) occurs before it is expected. Causes a transmit interrupt (XINT) if this bit and XSYNCERR in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Unexpected transmit frame sync did not occur 0x1: Unexpected transmit frame sync occurred.	RW	0
0	XUNDRN	Transmitter underrun flag. XUNDRN is set when the transmit serializer is instructed to transfer data from XBUF to XRSR, but XBUF has not yet been serviced with new data since the last transfer. Causes a transmit interrupt (XINT) if this bit and XUNDRN in <a href="#">MCASP_EVTCTLX</a> are set. This bit is cleared by writing a 1 to it. Writing a 0 has no effect.  0x0: Transmitter underrun did not occur 0x1: Transmitter underrun occurred.	RW	0

## 23.9 Serial Low-Power Inter-Chip Media Bus Controller

This section describes the features and functions of the serial low-power inter-chip media bus (SLIMbus®) controller.

### 23.9.1 SLIMbus Overview

There are two SLIMbus module instantiations, SLIMBUS1 and SLIMBUS2, in the device. SLIMbus1 is implemented in the audio backend (ABE) subsystem and is intended for the connection of external audio peripherals. SLIMBUS2 is at the top-level of the device and is intended for the connection of other types of peripherals.

The SLIMbus controller provides a bidirectional, multidrop, multichannel two-line serial interface between the device and other SLIMbus components in a system, such as audio codecs, Bluetooth® modules, and FM radio receivers/transmitters. Because of its versatility, the SLIMbus controller can play the role of a wide range of peripherals and clocked frame-oriented protocols ( I2S™, PCM, and TDM).

Figure 23-207 shows the SLIMbus1 controller highlight.

**Figure 23-207. SLIMbus1 Highlight**

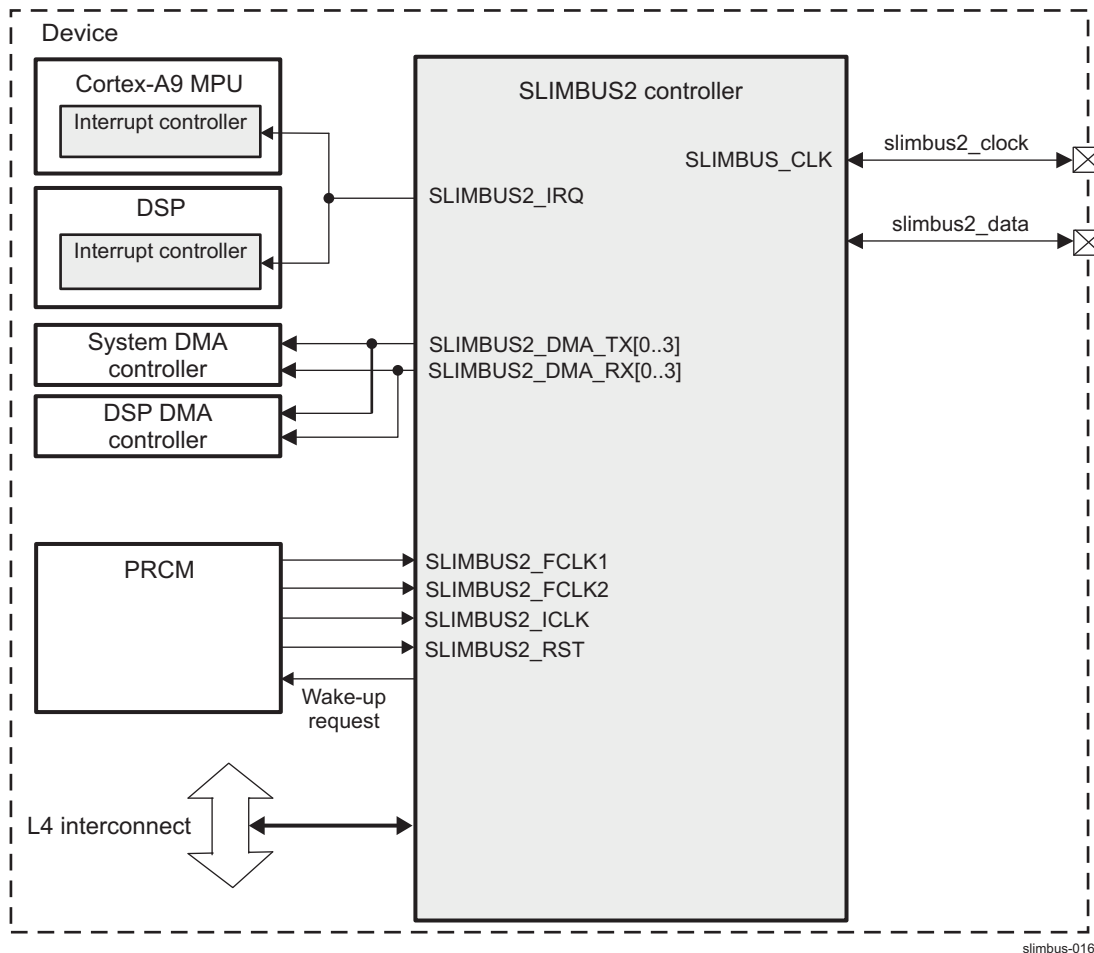

Figure 23-208 shows the SLIMbus2 controller highlight.

Figure 23-208. SLIMbus2 Highlight

### 23.9.1.1 Terminology

The SLIMbus module is by default the SLIMbus controller IP. The module implements a SLIMbus component by integrating together several submodules: a SLIMbus component contains a set of devices and the necessary logic needed to provide bus access to these devices.

Every component contains one Interface device and can contain additional devices belonging to other device classes (framer, manager, or generic devices).

- An interface device is the central status and control location of the component. All components have only one interface device.
- A framer device can generate the clock and synchronization information for the entire SLIMbus. Consequently, only one framer device (for all SLIMbus components) at a time can be active on the bus.
- A manager device controls the bus scheduling at high level: It assigns logical addresses to any device that is authorized to communicate using the bus, gives the bandwidth allocation, and so on. Only one manager device at a time can be active on the bus.
- A generic device implements the "useful" functionality of the component by sourcing/sinking the payload data. A component may include several generic devices so that each appears as a separate, standardized entity to the software driver.

**NOTE:** Typically, generic devices are used to transport data (rather than the specialized manager, framer, or interface devices, which typically do not feature data ports).

A device is a separately addressable entity within a SLIMbus component. Each device belongs to a single device class. After enumeration each device is addressed with a single logical address. A device (and especially a generic device) contains data ports to transmit and/or receive data. Each port is identified within the device by its port number (PN). A port is identified within the SLIMbus by its device address (logical address or enumeration address) and PN.

An enumeration address (EA) is a 48-bit value (composed of the manufacturer ID, product code, device ID, and instance value) that allows a device to receive messages.

A logical address (LA) is an 8-bit number used to uniquely identify an enumerated device on the bus.

### 23.9.1.2 Main Features

Each SLIMbus module includes the following main features:

- SLIMbus controller compliant with the MIPI SLIMbus standard version 1.01.00
- Support of seven SLIMbus devices:
  - One Interface device
  - One framer device
  - One manager device
  - Four generic devices
- SLIMBUS1: Eight TX and eight RX independent ports (data channels)
- SLIMBUS2: Four TX and four RX independent ports (data channels)
- FIFO access (one FIFO for transmit and one for receive), with DMA request (one line for transmit port and one line for receive port)
- SLIMBUS1: Message FIFO size is 32 bytes for transmit and 32 bytes for receive.
- SLIMBUS2: Message FIFO size is 32 bytes for transmit and 32 bytes for receive, by default. The message FIFO size can be reprogrammed to 64 (or 16 or 48) bytes if needed. However, typical use never exceeds 32 bytes.
- Data channel FIFO size is programmable for both modules.
- Programmable data length (sample size) from 4 to 32 bits
- Programmable port assignment to either of the four generic devices
- Supported transport protocols: Isochronous, pulled, pushed, asynchronous, and extended asynchronous transport protocols (the latter two in simplex and one-half duplex mode)
- No support for locked protocol
- SLIMbus clock rate: From 0 to 24.576 MHz

Each SLIMbus module has the following characteristics:

- The component is implemented by a digital controller (the current module), plus a physical layer (a set of CLK + DATA bidirectional input/output [I/O] drivers).
- Devices are logical entities implemented by a combination of hardware (automatic address decoding for message reception) and software (message decode, encode, etc.).
- Ports (and their mapping to data channels) are supported by the module hardware-implemented data channel agents. Each agent features a unidirectional FIFO, a DMA request, support for a number of transfer protocols, etc. One agent is used per port and per data direction: Transfer protocols are unidirectional and require only one data channel agent per data channel.

### 23.9.2 SLIMbus Environment

#### 23.9.2.1 SLIMbus Component Connection Example

Figure 23-209 shows an example of a system with the SLIMbus1 controller connected to an audio peripheral component.

Figure 23-209. SLIMbus1 Typical Application System Overview

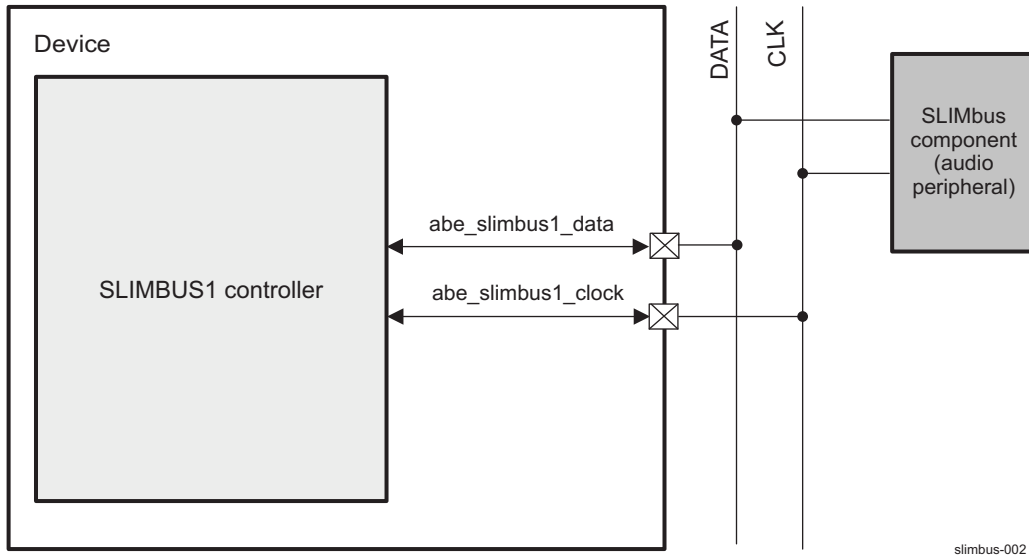

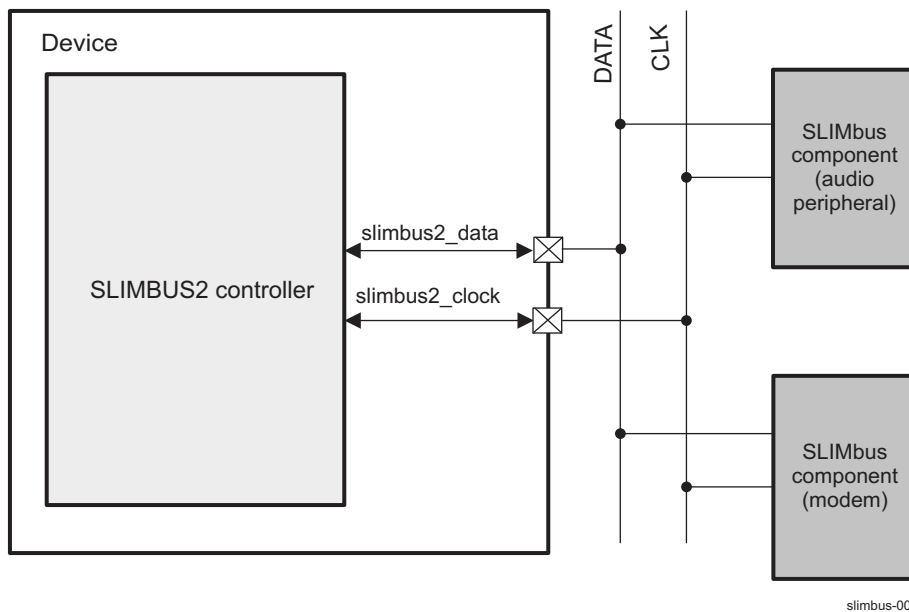

Figure 23-210 shows an example of a system with the SLIMbus2 controller connected to one audio peripheral component and one modem component.

Figure 23-210. SLIMbus2 Typical Application System Overview

The physical medium of SLIMbus is composed of two lines: CLK and DATA. All components of the bus are attached to both lines. The clock line (CLK) is driven by the (component containing the) active framer, and received (and used) by all other components on the bus. The data line (DATA) is driven alternately by all components, following the SLIMbus protocol.

The SLIMbus uses non-return-to-zero inverted (NRZI) signalling:

- A logical 1 is represented by a transition (a change) in the physical level.
- A logical 0 is represented by the same physical level as the previous bit.

### 23.9.2.2 SLIMbus Functional Interface

Table 23-660 describes the SLIMbus1 interface.

**Table 23-660. SLIMbus1 Signals Description**

Signal	I/O	Description	Value at Reset
abe_slimbus1_data	I/O	SLIMbus1 DATA pad	1
abe_slimbus1_clock	I/O	SLIMbus1 CLOCK pad	1

Table 23-661 describes the SLIMbus2 interface.

**Table 23-661. SLIMbus2 Signals Description**

Signal	I/O	Description	Value at Reset
slimbus2_data	I/O	SLIMbus2 DATA pad	1
slimbus2_clock	I/O	SLIMbus2 CLOCK pad	1

### 23.9.2.3 SLIMbus Protocols and Data Formats

#### 23.9.2.3.1 Frame Structure

The SLIMbus bitstream is transferred in time-division multiplexing (TDM) organization. TDM is a type of multiplexing in which two or more bitstreams are transferred apparently simultaneously as subchannels in one communication channel, but are physically taking turns on the channel. This organization allows SLIMbus to transfer control, data, and configuration information through only one DATA signal. The organization of information on the bus is called a frame structure. The frame structure is composed of five building blocks: cells, slots, subframes, frames and superframes.

- A cell is the smallest division of the SLIMbus data stream. A cell is defined as the region of the DATA line signal that lies between two consecutive positive edges of the CLK signal.
- A slot is a group of four contiguous cells. It is at the slot level that the SLIMbus DATA signal is time division-multiplexed between different channels.
- A frame is a group of 192 contiguous slots (768 cells). The first slot of each frame carries the frame-sync symbol.
- A subframe is the division of the frame structure at which control space and, if present, data space are interleaved. The subframe length can be 6, 8, 24, or 32 slots (24, 32, 96, and 128 cells).
- A superframe is composed of eight consecutive frames and contains a complete set of Framing Information.

Figure 23-211 shows the organization of the frame structure.

Figure 23-211. SLIMbus Frame Structure Overview

slimbus-010

### 23.9.2.3.2 Control and Data Channels

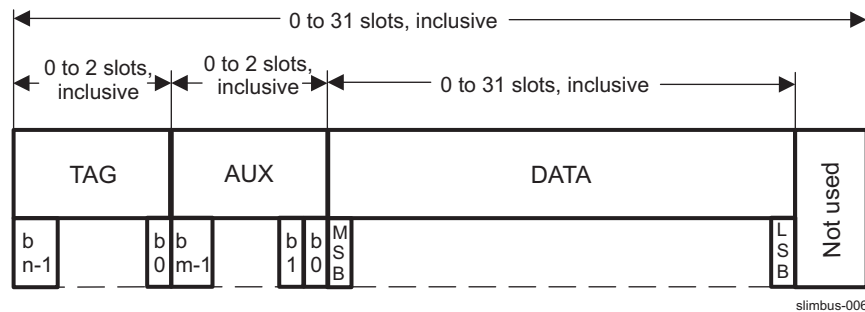

A frame is divided into two parts: the control space and the data space. The control space contains the information needed for a device to discover the bus state, to track messages, and for the messages themselves. The control space size is programmable by setting the control space width (number of control space slots per subframe) and the subframe length. Data space is interleaved with control space at the subframe level. Slots not explicitly allocated to control space are considered data space. The active manager can organize these slots into data channels to transport application-specific data streams between devices on the bus. Data space can contain up to 256 data channels.

A data channel is a stream of one or more contiguous slots organized in a consistent data structure that repeats at a fixed interval. The largest possible group of contiguous slots within a data channel is known as a segment.

A data channel connects one data source port and one or several data sink ports, depending on the protocol used. A port can be connected only to a single data channel at a time.

A segment is composed of three fields: TAG, auxiliary information (AUX), and data fields. These fields are organized within the segment, as shown in Figure 23-212. The exact composition of the segment depends on the transport protocol.

**Figure 23-212. Segment Organization**

### 23.9.2.3.2.1 Control Space Scheduling

The control space is a periodic allocation of blocks of contiguous slots with the following properties:

- Although the control space is composed of periodic blocks of 4-bit slots, it functions as a continuous stream of bits, and the interruptions for noncontrol space (that is, data space) sequences have no effect on its operation.
- The control space contains all synchronization references for the SLIMbus TDM structure; that is, it is not referenced to anything else because it is the reference.
- The control space scheduling changes only on reconfiguration boundaries.
- The subframe mode (SM) parameters unambiguously determine which slots belong to the control space.

The control space scheduling, encoded inside the SM, has the following structure:

- Each (fixed-length) frame is divided into a (whole) number of variable-sized subframes.
- The subframe length (SFL, encoded in the SM) is defined as the number of slots in a subframe.
- The control space is allocated in each subframe: The control-space width (CSW, also encoded in SM) is the number of control slots at the beginning of each subframe.

The control space is composed of  $192/\text{SFL}$  blocks of CSW slots each, starting at intervals of SFL slots (knowing that there are 192 slots per frame). If the frame slots from  $j = 0$  to  $j = (192-1)$  and the blocks from  $k = 0$  to  $k = (192/\text{SFL})-1$  are indexed, the control space occupies in each frame, for the whole range of  $k$ :

- from slot  $j = (k \times \text{SFL})$  included
- to slot  $j = (k \times \text{SFL}) + \text{CSW} - 1$  included

The control space is further subdivided into a framing channel, guide channel, and shared message channel (SMC).

- The framing channel is composed of:
  - A 1-slot frame sync symbol (FSS), at the beginning (slot 0) of each frame. The FSS is the reference for the position of the frame in the bitstream. The fixed scheduling means that it can be retrieved and tracked regardless of the SM.
  - A framing information slot, at mid-frame (slot 96). This fixed offset means that it can also be retrieved independently of the SM. The framing information contains (among others) the value of SM, which allows all devices to determine the structure of the control space.
  - For all legal control space structures (encoded in the SM), the framing channel (slot 0 and slot 96) is inside the control space.
- The guide channel is composed of a periodic transmission of the guide byte. It is sent in the first two control space slots of each superframe (a fixed block of eight frames), after the FSS, in slot 0. The guide channel provides a sync point for the SMC (defined as follows). The two guide channel slots are not necessarily contiguous, depending on the SM, which determines the control space length and the subframe length:
  - Guide channel = slot 1 and slot 32 for SM = 11

- Guide channel = slot 6 and slot 12 for SM = 4
- Guide channel = slot 1 and slot 2 for SM > 12
- Etc.
- The SMC is by definition the rest of the control space; that is, not already allocated to the framing or guide channel. All devices may concurrently try to access the SMC following an arbitration process. The SMC contains an even number of slots (whole number of bytes) per frame and per superframe.

### 23.9.2.3.2.2 Data Channel Allocation, Segments

The bandwidth allocated for a given data channel is determined by the segment distribution (SD) and segment length (SL) of the channel. This allocation is fixed, periodic, reserved exclusively for the channel, and changes only on reconfiguration boundaries.

- Each data channel is allocated periodic blocks of contiguous slots, called data segments.
- Segments are all of equal length (SL) (in slots).
- Segment scheduling is periodic (with true, cycle-accurate periodicity).
  - The segment period is called the segment interval (SI), in slots, encoded in the SD).
  - There is always a whole number of data segments per superframe, called the channel rate multiplier (CRM), encoded in SD). The CRM is another way to express the period, because  $CRM = 1536/SI$  (there are 1536 slots per superframe).
  - The segment window is another way to express the period: Each superframe can be divided into CRM segment windows, of length SI. For each data channel, each segment window contains one entire contiguous segment. Segments cannot cross segment window boundaries because some of the segments would then collide with the control space.
- The constant phase of a segment is the segment offset (SO), which is the distance between the start of the segment window and the start of the segment, in slots. SO is also encoded in SD, and its value is bounded as follows:
  - Because scheduling is periodic, offsets are defined modulo SI (that is, the segment must start inside the current window, not the next. SD encoding ensures that  $SO < SI$ ).
  - Segment must not overlap with control space. The consequences of that vary with SM (encoded in SM), but the following is true for all SMs:
    - $SO > CSW \geq 1$ : By definition, each superframe boundary is both the start of a frame (starting with CSW slots of control space; that is, at least one slot: the frame sync symbol) and the start of a segment window (the first window of the superframe, for all SD). To prevent overlap in that window, the segment must start (slot number = SO) after the control space end (slot number =  $CSW-1$ ). Although it can be encoded in SD, the value  $SO = 0$  is therefore illegal.
    - $SO+SL \leq SI$ : By definition, each superframe boundary is both the start of a frame (starting at the FSS slot) and the end of a segment window (the last window of the superframe, for all SD). To prevent overlap in that window, the segment must end (slot number =  $192-SI+SO+SL-1$ ) before the control space (frame sync symbol in slot 0 of following frame).

#### Notes on scheduling

- Data segments cannot cross a superframe/frame/subframe boundary, because the first slot (at least) of each subframe is allocated to the control space. This means that a data channel can be safely redefined (new SD, SL) at a reconfiguration boundary (which is also a superframe boundary), because that point cannot be in the middle of a segment.
- The composition of the segment, as defined by the transfer protocol (TP), and the contents of the channel have no affect on the allocation of the channel, although they must be compatible: the segment must be long enough (SL) to contain the TAG, AUX, and DATA fields. Some slots and some segments may remain unused.

### 23.9.2.3.2.3 Data Channel Presence

Data may or may not be present in each segment of the fixed, periodic series allocated to a data channel.

- The channel rate (CR) is defined as the number of data segments available per second. It depends on the channel rate multiplier (number of segments per superframe, encoded in SD[11:0]), and of the

SLIMbus clock frequency. It does not depend on the total length of the segment, data length, or other.

- The presence rate (PR) is defined as the number of data segments used (that is, that contain actual data) per second, and is encoded in PR[6:0]. It depends on the selected application.

Data channel presence properties:

- The data presence determination depends on the TP:
  - Pushed: TAG presence bit (P) driven by the data source
  - Pulled: TAG presence bit (P) driven by the data source upon request driven by the data sink (SRQ)
  - Asynchronous: TAG presence bit (P) driven by the segment owner (either side)
  - Isochronous: All segments contain data, no presence indication required (because it would always be asserted).
- The presence rate is necessarily smaller than the channel rate:  $PR \leq CR$ . At best they are equal, which is always the case for isochronous protocol.
- The difference between channel rate and presence rate (CR-PR) is unused bandwidth and must be kept as small as possible in most cases. In other words, the CR must be kept as small as possible for a given PR requirement. The unused bandwidth has multiple uses:
  - Padding: Adjust the required PR to a nonmultiple bus speed.
  - PR jitter margin: Allow the PR to fluctuate around an average, with enough margin to allow faster-than-average periods, that compensate for slower-than-average periods.
  - Wasted bandwidth

When data presence is not fully determined by the properties of the data channel or by the other side of the interface (pulled data source, pushed data sink), it must be controlled based on the capacity of the local system to generate data (for sources) and absorb data (for sinks).

- Pushed or asynchronous source: The data source (transmitter) asserts the presence bit ( $P = 1$ ) and transmits data when some data is available (in a transmit buffer).
- Pulled sink: The data sink (receiver) asserts the sample request ( $SRQ = 1$ ) when it can accept more data (in a receive buffer).

#### 23.9.2.3.2.4 Data Channel Segment Composition

The allocated size of a data channel segment is set by the SL parameter. The segment can be broken down into:

- TAG slots
- AUX slots
- DATA slots
- Unused slots

The parameters listed in [Table 23-662](#) configure the different lengths.

**Table 23-662. Segment Composition**

Parameter	Register Field	Segment Field	Size Range (Slots)	Comments
Segment length	SLIMBUS_DCR_CONF1 G1_j[9:5] / SLIMBUS_DCT_CONF1 G1_j[9:5] SL	Segment	1 to 31	Encoding 0x0 is reserved.
Transport protocol	SLIMBUS_DCR_CONF1 G1_j[3:0] / SLIMBUS_DCT_CONF1 G1_j[3:0] TP	TAG	0, 1, 2	N/A
AUX format	SLIMBUS_DCR_CONF1 G1_j[19:16] / SLIMBUS_DCT_CONF1 G1_j[19:16] AF	AUX	0, 1, 2	N/A

**Table 23-662. Segment Composition (continued)**

Parameter	Register Field	Segment Field	Size Range (Slots)	Comments
Data length	SLIMBUS_DCR_CONF1 G1_j[14:10] / SLIMBUS_DCT_CONF1 G1_j[14:10] DL	DATA	0 to 31	Encoding 0x0 is "all remaining slots," don't care if NVB is present.
Number of valid bytes	NVB (not in a register field, sent in the message)	DATA	0 to 28, even only	Encoded in AUX field, overrides DL, exists only for TP = extended asynchronous

**NOTE:**

- Explicit data length (DL) range is 1 to 31 slots. When encoding 0x0 is used, the DATA field occupies all remaining slots of the segment; that is, those not occupied by TAG and AUX. This allows the encoding of a 0-slot data length.
- NVB is available only in the extended asynchronous TP, which uses two TAG slots. The maximum remaining length is 31 (SL max) – 2 = 29 slots; that is, the maximum NVB is 14 bytes = 28 slots ≤ 29 (because NVB is byte-granular and cannot encode odd slot counts).
- Not all combinations are legal. For example, the DATA field of a pushed channel (TP = 0x1: 1 TAG slot) with no AUX information (AF = 0x0) and a 5-slot overall segment length (SL = 0x5) can have only one to four slots, encoded respectively as DL = 0x1, 0x2, 0x3, and 0x4/0x0.

In the current SLIMbus module (the OMAP™ SLIMbus module):

- The SL, TP, AF, and DL setup parameters are received from the appropriate control messages (inside or outside reconfiguration sequences), and programmed into appropriate control registers. They are typically static over long periods.
- The TAG slots are generated (driven) and decoded (received) on the fly by the hardware:
  - The first TAG slot (if present, for all but isochronous TP) negotiates the value of the presence bit (P).
  - The second TAG slot (for extended asynchronous TP) contains the NVB field, which indicates the number of valid bytes contained in the segment. When the presence bit (P) is not asserted, the NVB is then not driven and implicitly = 0. There is no separate NVB setup register, as for SL, TP, AF, etc.
- AUX slots (if present) go through the same data path as the DATA slots. The decoding/encoding of the AUX information is assumed to be done outside the SLIMbus controller. Their value has no effect on the protocol.
- DATA slots (if present) go through the same data path as the AUX slots. Their value has no effect on the protocol.
- The encoding/decoding, merging/splitting between the different FIFO-stored slots is assumed to be done outside the SLIMbus controller; that is, before writing to the FIFO (in transmit) and after reading from the FIFO (in receive). No support logic is provided for those functions.
- When no data is transmitted during a given segment (presence bit P/VP = 0), only the first TAG slot (if any) is actively driven and the AUX/DATA slots are not used.

Table 23-663 gives the three cases of size calculation formulas for the TAG, AUX, and DATA fields, plus the FIFO-stored section of a segment, in slots with:

- SL, DL, NVB, TP, AF, and DL, the standard SLIMbus fields, as their integer value
- Size(TP), the TAG field size in slots, as a function of the TP (see *MIPI Alliance Specification for SLIMbus Version 1.01.00*)
- Size(AF), the AUX field size in slots, as a function of the AUX format ID AF (see *MIPI Alliance Specification for SLIMbus Version 1.01.00*)

**Table 23-663. Data Segment Field Size Calculations**

Case	TAG Size = Size (TP)	AUX Size = Size (AF)	DATA Field Size	FIFO-Stored Size
Extended asynchronous protocol (TP = 0x6 or 0x7)	2	0, 1, 2	1 + size(AF) + (2 x NVB)	1 + size(AF) + (2 x NVB)
Other TP, DL > 0	0, 1	0, 1, 2	DL	DL + size(AF)
Other TP, DL = 0	0, 1	0, 1, 2	SL – size(TP) – size(AF)	SL – size(TP)

### 23.9.2.3.3 SLIMbus Transfer Protocols

The SLIMbus module supports seven the following protocols:

- Isochronous
- Pushed
- Pulled
- Asynchronous
  - Simplex
  - Half-duplex
- Extended asynchronous
  - Simplex
  - Half-duplex

**Table 23-664. SLIMbus Transfer Protocols**

Transfer Protocol	Multicast Capability	Data Length	AUX Length	LPCM (DT)	CTS Forcing	Pairing
Isochronous	Yes	1–8 slots	0–2	Yes	N/A	Yes
Pushed	Yes	1–8 slots	0–2	Yes	N/A	Yes
Pulled	No	1–8 slots	0–2	Yes	N/A	Yes
Asynchronous, simplex	No	1–8 slots	0–2	Yes	Yes	No
Asynchronous, half-duplex	No	1–8 slots	0–2	Yes	Yes	No
Extended asynchronous, simplex	No	Any (NVB)	0	N/A	Yes	N/A
Extended asynchronous, half-duplex	No	Any (NVB)	0	N/A	Yes	N/A

#### 23.9.2.3.3.1 Isochronous Transfer Protocol

The isochronous transfer protocol is a unidirectional, streaming, multicast communication mode. Data is to be present in all allocated segments (this transfer protocol has no TAG field).

- 100 percent of the bandwidth is usable for AUX + DATA slots (no control TAG overhead).
- Because no flow control exists, multiple data sinks may be connected to the same data source (multicast capability).
- The range of possible presence rates (number of segments per second) is limited to simple ratios of the SLIMbus clock. If several data streams with incompatible presence rates must be multiplexed over the same bus, no combination of isochronous-based schedulings works. In those cases, the pushed or pulled transfer protocol must be used.

### **23.9.2.3.3.2 Pushed Transfer Protocol**

The pushed transfer protocol is unidirectional, multicast, and controlled by the data source (transmitter), which pushes data toward the data sink (receiver). The presence of valid data in a segment is indicated by the presence (P) bit in the TAG field, driven by the source. The TAG field is composed of four bits: one reserved, one strobe (STR) bit, one reserved, and one presence (P) bit.

- The pushed data source is the master of the data flow through the presence (P) bit .
- The pushed data sink is slaved to the presence (P) bit..
- The TAG control field creates a 1-slot overhead per segment. The rest of the segment is usable for AUX + DATA slots.
- Because the flow control is generated by the source with no feedback from the sink, multiple data sinks may be connected to that source (multicast capability).
- The presence rate can be modulated at will from 0 (no data at all) to the full segment rate (data present in all segments) according to the requirement. Intermediate settings allow several streams with incompatible presence rates to be multiplexed over the same bus, at the cost of less than 100 percent bandwidth utilization (for example, a 44.1-kHz sample flow transmitted over a reserved 48-kHz data channel).

### **23.9.2.3.3.3 Pulled Transfer Protocol**

The pulled transfer protocol is unidirectional, unicast, and controlled by the data sink (receiver), which pulls data from the data transmitter (source). The presence of valid data in a segment is indicated by the presence bit (P) in the TAG field, driven by the source. The TAG field is composed of four bits: one reserved, one sample request (SRQ) bit, one reserved, and one presence (P) bit.

- The pulled data sink is the master of the data flow through the (SRQ bit, itself determining the value of the presence bit (P), driven by the data source.
- The pulled data source is slaved to the SRQ bit.
- The TAG control field creates a 1-slot overhead per segment. The rest of the segment is usable for AUX + DATA slots.
- Because the flow control is generated by the sink with feedback from the source, only a single data sink may be connected to that source (unicast-only, no multicast capability).
- The presence rate can be modulated at will from 0 (no data at all) to the full segment rate (data present in all segments) according to the requirement. Intermediate settings allow several streams with incompatible presence rates to be multiplexed over the same bus, at the cost of less than 100 percent bandwidth utilization (for example, a 44.1-kHz sample flow transmitted over a reserved 48-kHz data channel).

### **23.9.2.3.3.4 Asynchronous Transfer Protocols**

The asynchronous transfer protocols are typically used for on-demand, packet-based data transfers (that is, nonstreaming). Because the SLIMbus protocol and architecture are optimized for data streaming scenarios, asynchronous protocols are considered a useful extension rather than a central feature of the SLIMbus. An asynchronous data channel gets the same periodic, reserved, fixed-bandwidth slot allocation as a streaming (for example, isochronous) data channel.

An asynchronous data channel is a point-to-point (unicast) communication link between a primary owner device and a secondary owner device.

A half-duplex asynchronous channel is a bidirectional data channel.

- A handshake protocol is used to determine the direction of the channel through its ownership. The channel owner is the data source, and the other is the sink.
- Once the ownership (data direction) is determined, both source and sink can regulate the flow of data, depending on data availability (source) and free buffer availability (sink).
- Half-duplex ports can be used when bandwidth is sparse (compare simplex and full duplex).
- However, each half-duplex port requires two data channel agents (with FIFO and control logic) inside the controller, one in each direction, contrary to all other asynchronous modes and transfer protocols. Those two associated agents must be configured coherently.

A simplex asynchronous channel is a unidirectional data channel, a simplified version of the half-duplex channel defined perviously. The ownership is never given to the secondary owner.

- Secondary owner never requests the channel. As a consequence, the roles are never exchanged: the primary owner is always data source, and the secondary owner always data sink.
- Simplex ports are used in pairs of opposite directions to implement full-duplex communication, where each direction has its own reserved bandwidth. As far as the controller is concerned, the two simplex links are treated as fully independent data channels, with independent configurations; only the higher layers (software) associate the two.
- Two simplex ports use the same number of data channel agents (that is, FIFOs and control logic) as a single half-duplex port (two per controller in each case; the only difference is in the bandwidth management).

#### 23.9.2.3.3.5 Extended Asynchronous Transfer Protocols

The extended asynchronous transfer protocols are extensions of the plain asynchronous transfer protocol. The main features are retained: point-to-point (unicast) between a primary and a secondary owner, simplex (unidirectional) or half-duplex (bidirectional), and so on.

The difference lies in a more flexible management of the DATA slots: In the plain asynchronous TP, each segment contains no data (presence [P] bit = 0) or a fixed amount of data (P = 1), preconfigured for all segments. In the extended asynchronous mode, a number of valid bytes (NVB) 4-bit field is added before each segment, in a second TAG slot, to indicate a variable number of significant DATA slots (the granularity is 1 byte = 2 slots).

---

**NOTE:** AUX slots (when present; not in the current implementation) are not counted in NVB, just as they are not counted in DL in the plain asynchronous TP.

---

#### 23.9.2.3.4 Half-Duplex Versus Full-Duplex Asynchronous Configurations

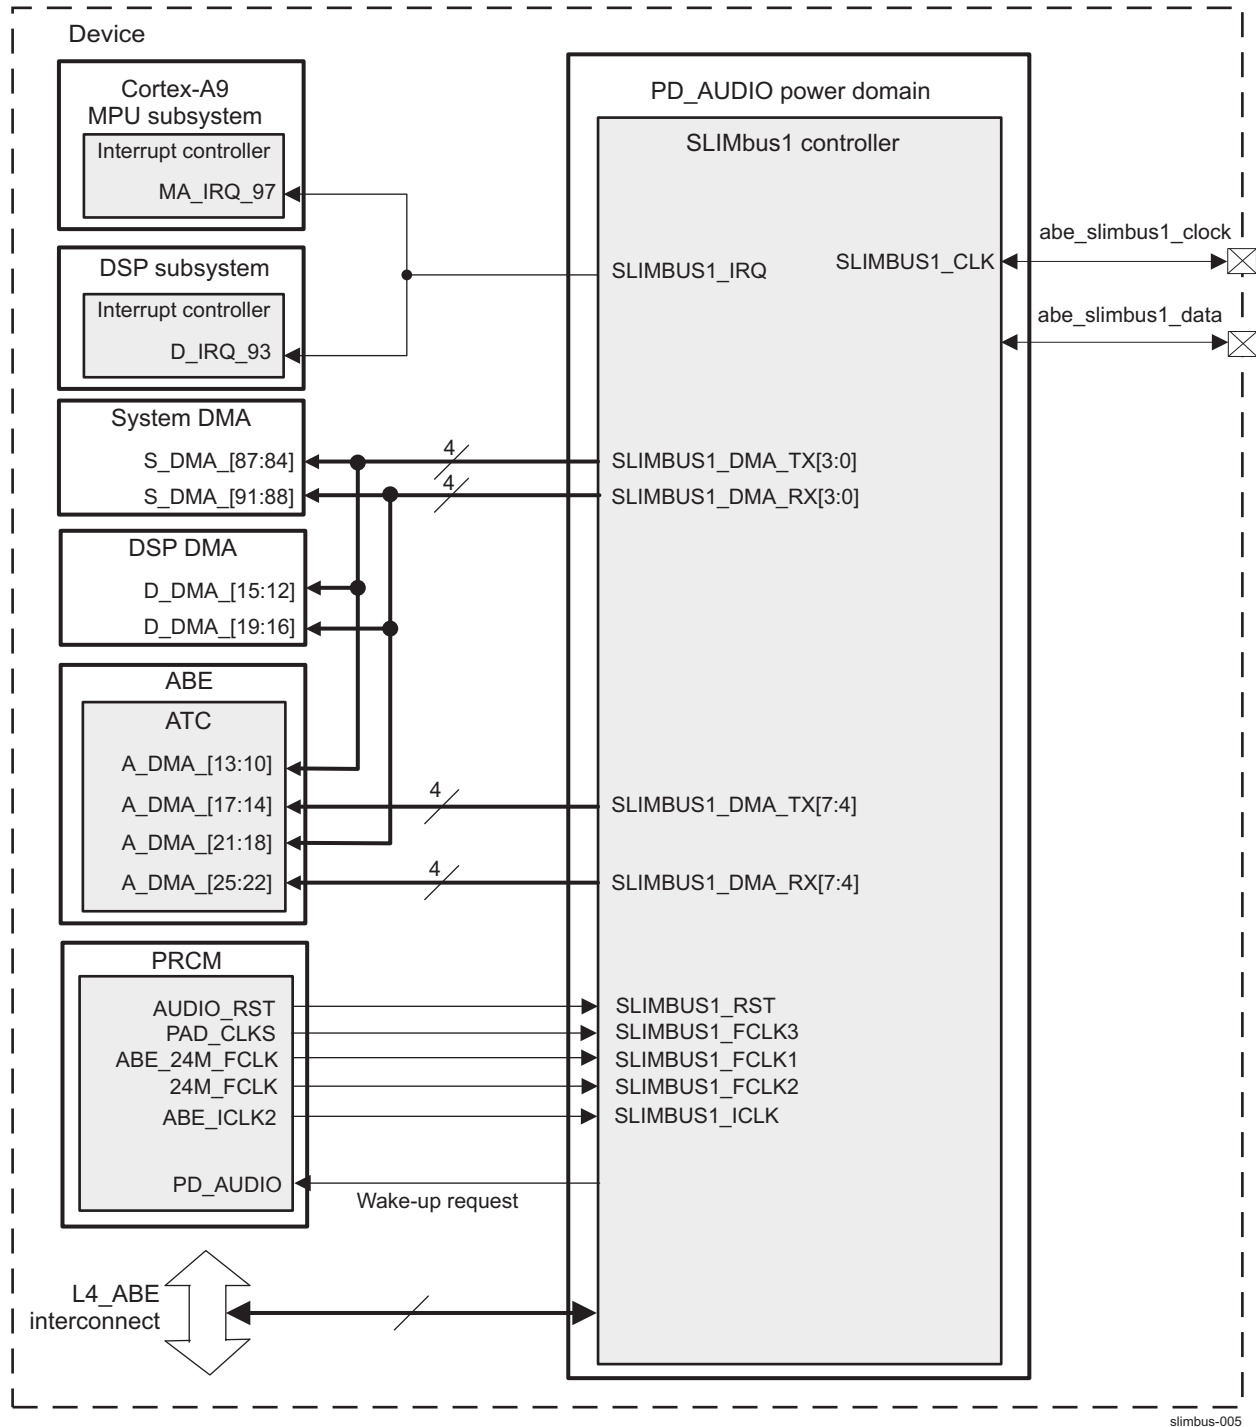

Half-duplex and full-duplex modes are similar in their operation, in that they use two data channel agents (FIFOs and associated control hardware) in opposite directions (one TX, one RX) to transmit and receive data over a bidirectional, unicast (point-to-point) asynchronous link. However, there are differences:

- The half-duplex setup uses a single data channel (in the SLIMbus sense); that is, a single reserved data space segment allocation, used alternately in both directions, according to the dynamic ownership negotiated in the TAG slots.
- The full-duplex setup uses two data channels (in the SLIMbus sense); that is, two separate reserved data space segment allocations, each used in a fixed direction (opposite of the other) (that is, with no ownership change).

### 23.9.3 SLIMbus Integration

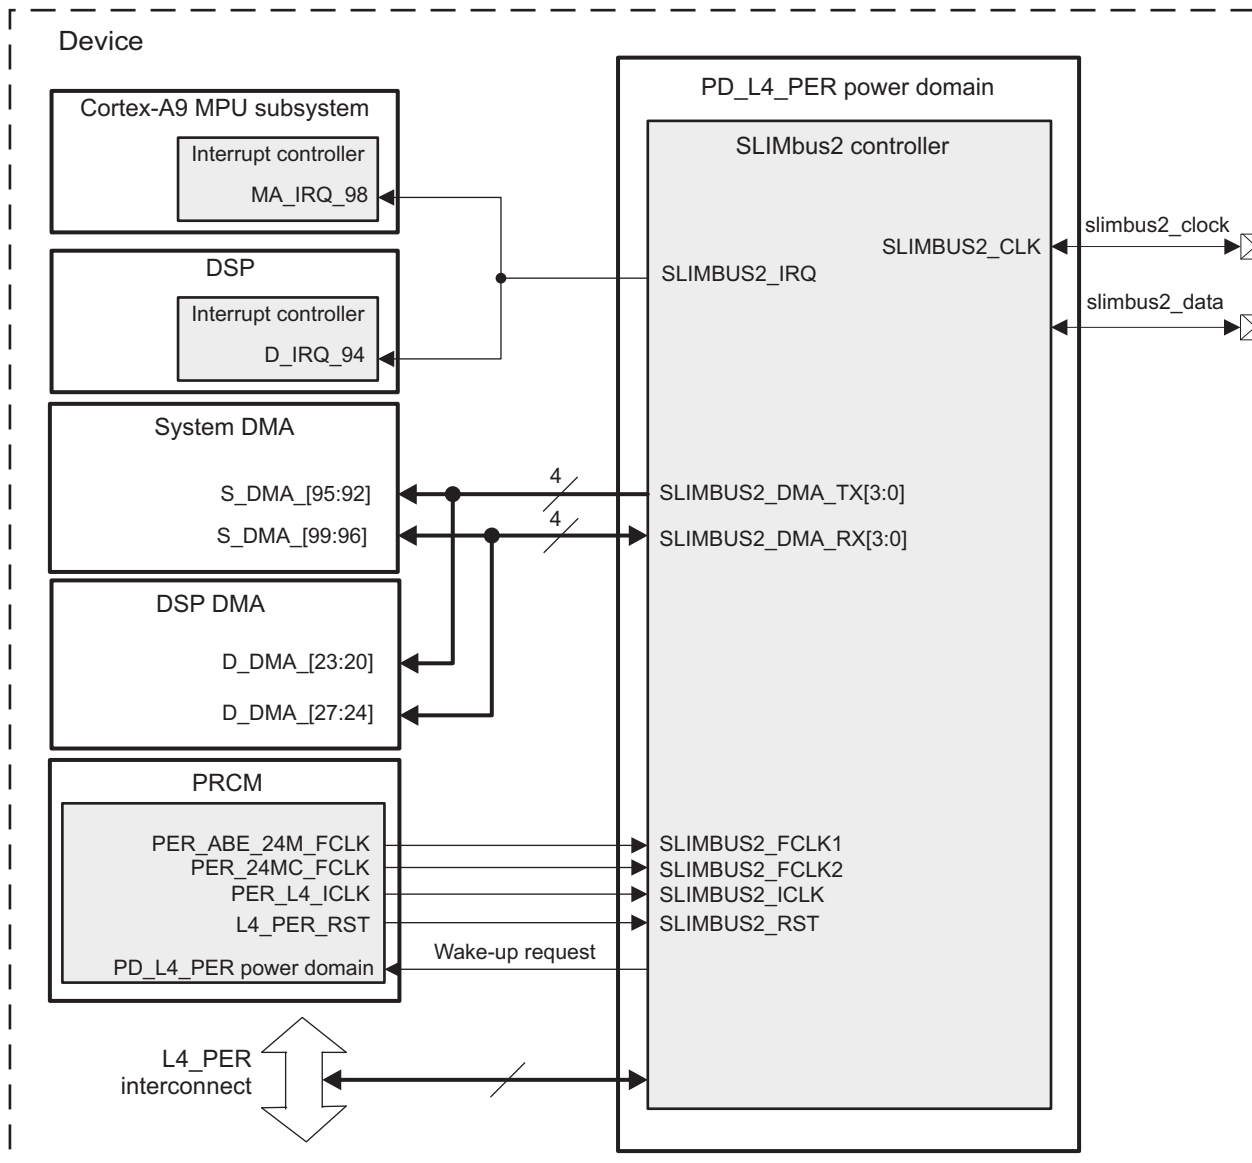

Figure 23-213 and Figure 23-214 show the integration of the two SLIMbus module instantiations in the device. The SLIMBUS1 module is part of the ABE module

Figure 23-213. SLIMBUS1 Integration

**Figure 23-214. SLIMBUS2 Integration**

slimbus-003

Table 23-665 through Table 23-667 summarize the integration of the modules in the device.

**Table 23-665. Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
SLIMBUS1	PD_AUDIO	Yes	L4_ABE
SLIMBUS2	PD_L4_PER	Yes	L4_PER

**Table 23-666. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SLIMBUS1	SLIMBUS1_FCLK3	PAD_CLKS	PRCM	Functional clock, divided by 4 or more inside SLIMbus module. The source is the abe_clks pin gated by the PRCM module.
	SLIMBUS1_FCLK1	ABE_24M_FCLK	PRCM	Functional clock, divided by 4 or more inside SLIMbus module
	SLIMBUS1_ICLK	ABE_ICLK2	PRCM	Interface clock
	SLIMBUS1_FCLK2	24M_FCLK	PRCM	Functional clock, divided by 4 or more inside SLIMbus module
	SLIMBUS1_CLK	SLIMBUS_UCLKS	abe_slimbus1_clock pin	SLIMBUS clock, may or may not be locally generated
SLIMBUS2	SLIMBUS2_ICLK	PER_L4_ICLK	PRCM	Interface clock
	SLIMBUS2_CLK	PAD_SLIMBUS_CLKS	slimbus2_clock pin	SLIMBUS clock, may or may not be locally generated
	SLIMBUS2_FCLK2	PER_24MC_FCLK	PRCM	Functional clock, divided by 4 or more inside SLIMbus module
	SLIMBUS2_FCLK1	PER_ABE_24M_FCLK	PRCM	Functional clock, divided by 4 or more inside SLIMbus module
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
SLIMBUS1	SLIMBUS1_RST	AUDIO_RST	PRCM	Reset to SLIMbus1 module
SLIMBUS2	SLIMBUS2_RST	L4_PER_RST	PRCM	Reset to SLIMbus2 module

**Table 23-667. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
SLIMBUS1	SLIMBUS1_IRQ	MA_IRQ_97	Cortex-A9 INTC	SLIMBUS1 interrupt to Cortex-A9 MPU
	SLIMBUS1_IRQ	D_IRQ_93	DSP INTC	SLIMBUS1 interrupt to DSP
SLIMBUS2	SLIMBUS2_IRQ	MA_IRQ_98	Cortex-A9 INTC	SLIMBUS2 interrupt to Cortex-A9 MPU
	SLIMBUS2_IRQ	D_IRQ_94	DSP INTC	SLIMBUS2 interrupt to DSP
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
SLIMBUS1	SLIMBUS1_DMA_TX0	A_DMA_10	aDMA (Audio DMA)	SLIMbus module 1 – transmit request channel 0
	SLIMBUS1_DMA_TX1	A_DMA_11	aDMA	SLIMbus module 1 – transmit request channel 1
	SLIMBUS1_DMA_TX2	A_DMA_12	aDMA	SLIMbus module 1 – transmit request channel 2
	SLIMBUS1_DMA_TX3	A_DMA_13	aDMA	SLIMbus module 1 – transmit request channel 3
	SLIMBUS1_DMA_TX4	A_DMA_14	aDMA	SLIMbus module 1 – transmit request channel 4
	SLIMBUS1_DMA_TX5	A_DMA_15	aDMA	SLIMbus module 1 – transmit request channel 5
	SLIMBUS1_DMA_TX6	A_DMA_16	aDMA	SLIMbus module 1 – transmit request channel 6
	SLIMBUS1_DMA_TX7	A_DMA_17	aDMA	SLIMbus module 1 – transmit request channel 7
	SLIMBUS1_DMA_RX0	A_DMA_18	aDMA	SLIMbus module 1 – receive request channel 0

**Table 23-667. Hardware Requests (continued)**

	SLIMBUS1_DM A_RX1	A_DMA_19	aDMA	SLIMbus module 1 – receive request channel 1

## 23.9.4 SLIMbus Functional Description

### 23.9.4.1 SLIMbus Block Description

Figure 23-215 shows the the overall architecture of a SLIMbus module.

Figure 23-215. SLIMbus Block Diagram

slimbus-007

- The red arrows represent the shared memory arbitration interface, from the arbiter to each agent.
- The blue arrows represent the shared memory access interface, from the memory access module to each agent.
- The green arrows represent the frame layer sync information broadcasted to all SB-side agents.

### 23.9.4.2 SLIMbus Clock Configuration

Most of the SLIMbus module runs off two main clocks: the L4 interface clock for the data input and output registers, and the control and status control registers; and the SLIMbus clock, taken from the serial interface (CLK line) for the SLIMbus-side logic.

The SLIMbus controller operates as clock source component (active framer), which drives the SLIMbus clock line CLK, or as clock receiver component, which gets its clock from the same CLK line.

- As a clock receiver, the module has by definition no control over the clock activity and can perform required operations based on that. Even clock pause is mostly transparent as far as the receiver logic is concerned (that is, everything happens as if time had stopped at the clock pause, and activity resumes seamlessly upon clock restart).
- As a clock source (also called active framer), the module relies on a local functional clock to drive the SLIMbus clock line. Such a functional clock is selected out of the available clock inputs. The appropriate input is expected to be active whenever it is needed (that is, when selected and used to run the SLIMbus clock and/or the module internal logic). In this case, the SLIMbus clock output is generated by selecting and dividing one functional clock input provided to the controller. Internal logic selects and divides the appropriate one depending on the SLIMbus configuration.

### 23.9.4.3 Software Reset

The [SLIMBUS\\_CMP\\_SYSCONFIG\[1\] SOFTRESET](#) bit controls the software reset; writing 1 to this bit starts a soft reset sequence.

### 23.9.4.4 System Power Management and Wakeup

#### 23.9.4.4.1 Wake-Up Request

Both SLIMbus controllers are wake-up capable.

There are several levels of wake-up capability:

- Most IRQ events are potential wake-up sources, because they can occur while the external interface is idle, assuming the external and SLIMbus clocks are still running.
- The clock restart IRQ event (the [SLIMBUS\\_FR\\_INFO\[5\] CLOCK\\_RESTART](#) bit) following a clock pause is the only one that can take place when all module clocks are stopped.

#### 23.9.4.4.2 Power Management

[Table 23-668](#) describes power-management features available for the SLIMbus module.

---

**NOTE:** For the description of the IdleMode feature, see [Chapter 3, Power, Reset, and Clock Management](#).

---

**Table 23-668. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	<a href="#">SLIMBUS_CMP_SYSCONFIG[8] AUTOGATINGDISABLE</a>	Internal clock autogating is intended to conserve power when the module is not in use.
Slave idle modes	<a href="#">SLIMBUS_CMP_SYSCONFIG[3:2] IDLEMODE</a>	Force-idle, no-idle, smart-idle, and smart-idle wake-up-capable modes are available.
Wake-up sources enable	<a href="#">SLIMBUS_FR_INFO[5] CLOCK_RESTART</a> and most IRQ events	See <a href="#">Section 23.9.4.4.1</a>

#### 23.9.4.4.3 SLIMbus Boot and Reset Procedures

The SLIMbus standard defines different levels of resets and default states from which to boot. They are implemented by a mix of software and hardware.

**NOTE:** This does not include the module-wide software or hardware resets of the controller, which simply wipe off the entire logic with no consideration for any potentially ongoing SLIMbus operation.

Table 23-669 summarizes the control bit fields to set in the various reset and/or boot sequences. Any combination other than the ones described here may yield unpredictable results.

**Table 23-669. Reset and Boot Control Summary**

Register / Field	SLIMBUS_FR_CONTROL		SLIMBUS_FL_CONTROL		
	Boot	bus_reset	Boot	bus_shutdown	force_reconfigure <sup>(1)</sup>
Clock receiver boot <sup>(2)</sup>			1		1
Clock source boot	1				1
Clock receiver component reset <sup>(2) (3)</sup>			1		1
Clock source component reset		1			1
Bus reset <sup>(4) (5)</sup>		1			
Bus shutdown <sup>(4)</sup>				1	

<sup>(1)</sup> When used, the SLIMBUS\_FL\_CONTROL[2] FORCE\_RECONFIGURE bit must be set (written to 1) last, because its action can be immediate. Other control bits can be set in any order.

<sup>(2)</sup> The controls for boot and component reset look identical for the clock receiver. The difference is in the initial state of the component: in the first case, the component is in the undefined state (not started), in the second case it is operational.

<sup>(3)</sup> The clock receiver component reset case shown here corresponds to the reception by the component interface of the RESET\_DEVICE. In the two other cases, a bus reset is detected and the hardware automatically goes to the correct state.

<sup>(4)</sup> The bus reset and shutdown belong to a reconfiguration (message) sequence and take place on the reconfiguration boundary: the SLIMBUS\_FL\_CONTROL[2] FORCE\_RECONFIGURE is therefore not used.

<sup>(5)</sup> The bus reset is executed only by the clock source (active framer).

#### 23.9.4.4.3.1 Clock Receiver Component Boot

A clock receiver boot sequence is initiated when a component that is not the default active framer decides to join the SLIMbus. Provided the clock line is driven (that is, a framer is active), the clock receiver must eventually acquire the synchronization.

Clock receiver boot sequence:

- Initial state: Out of hardware module reset or following a SLIMbus shutdown
- Write 1 to the SLIMBUS\_FL\_CONTROL[0] BOOT bit to start the clock receiver.
- Write 1 to the SLIMBUS\_FL\_CONTROL[2] FORCE\_RECONFIGURE bit.

#### 23.9.4.4.3.2 Clock Source Component Boot

Source component is, by definition, the component including the active framer (that is, the clock driver). A clock source boot sequence is initiated when a component that is the default active framer joins the SLIMbus. The clock source drives the clock line and runs the SLIMbus boot sequence, allowing the connected clock receivers to synchronize to it.

**NOTE:** The component knows in advance that it is the only default active framer, in charge of booting the bus: That information must be available for the component, as well as the default SM, CG, and RF configuration parameters.

Clock source boot sequence:

- Initial state: The component is the designated default active framer and is out of hardware module reset or follows a SLIMbus shutdown.
- Write 1 to the SLIMBUS\_FR\_CONTROL[0] BOOT bit.
- Write the basic bus configuration, to be used by the active framer device to generate the clock and the framing channel contents:
  - Subframe mode (M) in the SLIMBUS\_FL\_SM[4:0] SM bit field: Sets the control space width and

- subframe length
- Clock gear (G) in the [SLIMBUS\\_FL\\_CG\[3:0\]](#) CG bit field: The root/SLIMbus frequency ratio is defined as  $2^{(10-CG)}$
- Root frequency (F) in the [SLIMBUS\\_FL\\_RF\[3:0\]](#) RF bit field: Sets the root frequency
- Clock source selection, in the [SLIMBUS\\_FR\\_CLOCK\\_SOURCE\[6:4\]](#) CLKSEL and [SLIMBUS\\_FR\\_CLOCK\\_SOURCE\[3:0\]](#) CLKDIV bit fields
- The relationships (and limitations) between CG, RF, and the clock source selection also apply here.
- Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[2\]](#) FORCE\_RECONFIGURE bit to trigger the sequence execution
- The clock source starts immediately and eventually drives the CLK line and allows other components (clock receivers) to join the bus.

#### 23.9.4.4.3.3 Bus Reset

A bus reset is a specific DATA and CLK sequence run by the active framer, scheduled after the bus has already booted, and which causes all components of the bus to reset. For more information about the bus reset detection mechanism, see [Section 23.9.4.4.3.4, Component Reset](#).

The bus reset is requested by the manager device through a reconfiguration sequence, and is run by the active framer starting at the following reconfiguration boundary.

Bus reset sequence, to be executed by all components:

- Write 1 to the [SLIMBUS\\_FR\\_CONTROL\[1\]](#) BUS\_RESET bit.
- Wait for the end of the reconfiguration sequence to execute:
  - On the clock source (active framer), this must trigger a bus reset sequence.
  - On any other device (that is, a clock receiver), this must have no direct effect (other than clearing the [SLIMBUS\\_FR\\_CONTROL\[1\]](#) BUS\_RESET bit).
  - Because all bus devices are being reset (bus is rebooted, almost from the beginning), the configuration (M, G, F parameters) can change (because those parameters must be reacquired by all attached devices as part of the resynchronization sequence, this is not a problem).

#### 23.9.4.4.3.4 Component Reset

A component reset implies the (device) reset of all devices within that component. When a component reset condition is detected, software must therefore run the device reset sequence defined in [Section 23.9.4.4.3.5, Device Reset](#), as many times as necessary. Additional operations are also required.

A component reset has two possible causes:

- Bus reset sequence detected
- Interface device of the local component receives a reset order. (This is not a reconfiguration message; that is, the reset is effective immediately upon reception. Nevertheless, a specific action is needed to perform the device reset:)
  - Use the [SLIMBUS\\_FL\\_CONTROL\[1\]](#) COMPONENT\_RESET bit.
  - If the component is a clock receiver (clock receiver FSM), the sequence is :
    - Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[0\]](#) BOOT bit.
    - Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[2\]](#) FORCE\_RECONFIGURE bit to trigger the reset execution.
  - If the component is the active framer (clock source FSM), the sequence is :
    - Write 1 to the [SLIMBUS\\_FR\\_CONTROL\[1\]](#) BUS\_RESET bit.
    - Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[2\]](#) FORCE\_RECONFIGURE bit to trigger the reset execution.
    - The effect of a clock source component reset is the same as a bus reset, except it takes place immediately instead of waiting for a reconfiguration boundary.

#### 23.9.4.4.3.5 Device Reset

A device reset can have several causes:

- Component reset of the receiver component containing that device, caused by a bus reset reconfiguration message. If the cause of the device reset is a component reset, the sequence defined in [Section 23.9.4.4.3.4, Component Reset](#), is applied.
- A reset order targeted at the device itself. (This is not a reconfiguration message; that is, it is effective immediately upon reception. In this case, no additional action is required.)

The following sequence must be executed for all devices:

- Release the logical address (LA) of the device by clearing (writing 0 to) the [SLIMBUS\\_DEV\\_LA\\_i\[8\]](#) LA\_ENABLE bit. It is assumed that the [SLIMBUS\\_DEV\\_LA\\_i\[9\]](#) EA\_ENABLE bit remains set (1). The device returns to the default, nonenumerated state where it is identified by its hard-coded enumeration address (EA). The [SLIMBUS\\_DEV\\_LA\\_i\[7:0\]](#) LA bit may be assigned to another device by the bus manager (that is, keeping track of all device resets).
- The following hardware bits must also be cleared (by writing 1) when the device to which they belong (identified by the message target LA) is being reset:
  - The [SLIMBUS\\_FR\\_INFO\[2\]](#) FS, [SLIMBUS\\_FR\\_INFO\[1\]](#) FI, and [SLIMBUS\\_FR\\_INFO\[0\]](#) GC\_TX\_COL bits (framer device-specific IEs)
  - The [SLIMBUS\\_FL\\_INFO\[2\]](#) LOST\_FS, [SLIMBUS\\_FL\\_INFO\[1\]](#) LOST\_SFS, and [SLIMBUS\\_FL\\_INFO\[0\]](#) LOST\_MS bits (interface device-specific IEs)
  - The [SLIMBUS\\_SMR\\_INFO\[0\]](#) MC\_TX\_COL, [SLIMBUS\\_SMT\\_INFO\[0\]](#) MC\_TX\_COL bit (primitives of interface device-specific IE)
  - The [SLIMBUS\\_DCT\\_INFO\\_j\[0\]](#)/[SLIMBUS\\_DCR\\_INFO\\_j\[0\]](#) DATA\_TX\_COL bit (generic device IEs)
- Reset all pending reconfiguration parameters by writing 1 to the [SLIMBUS\\_FL\\_CONTROL\[7\]](#) CLEAR\_RECONFIGURATION bit (see [Section 23.9.4.4.4](#)).
- Reset all device ports (if any), as explained in [Section 23.9.4.4.3.6, Port Reset](#).

#### 23.9.4.4.3.6 Port Reset

A port reset can have several causes:

- Device reset of the device to which the port belongs, which may be part of a wider component of the bus reset
- Synchronization loss. Although all ports are reset, this is not equivalent to a device reset, because logical addresses are not cleared.
- Specific software messages reception

#### 23.9.4.4.3.7 Bus Shutdown

A bus shutdown stops definitively all SLIMbus activity (CLK and DATA) and brings the bus back to its original (preboot) state. When the shutdown is executed, the system must reboot from scratch.

The bus shutdown is requested by the manager device through a reconfiguration sequence.

Bus shutdown sequence:

- Write 1 to the [SLIMBUS\\_FL\\_CONTROL\[6\]](#) BUS\_SHUTDOWN bit. This is valid for an active framer (clock source) or a clock receiver.
- Wait for the end of the reconfiguration sequence to execute.
- Beyond that point, the bus is down and can be restarted only by a boot sequence.

#### 23.9.4.4.4 SLIMbus Reconfigure Parameters

During a reconfiguration message sequence, the controller accumulates parameter changes to be applied at the following reconfiguration boundary. If the sequence does not complete correctly, all changes are discarded. In specific boot and reset cases, the parameters are also set or reset automatically.

This section provides an overview of all the configuration register fields and their use.

Writing 1 to the `SLIMBUS_FL_CONTROL[7] CLEAR_RECONFIGURATION` bit has an immediate effect on the configuration registers.

- The following registers fields revert to their current value; that is, the value currently used for SLIMbus operations. The value previously written in is discarded.
  - The `SLIMBUS_FL_SM[4:0]` SM bit field: Sets the control space width and subframe length.
  - The `SLIMBUS_FL_CG[3:0]` CG bit field: The root/SLIMbus frequency ratio is defined as  $2^{(10-G)}$ .
  - The `SLIMBUS_FL_RF[3:0]` RF bit field: Sets the root frequency
  - The `SLIMBUS_FR_CLOCK_SOURCE[6:4]` CLKSEL: Clock input source selection
  - `SLIMBUS_FR_CLOCK_SOURCE[3:0]` CLKDIV bit field: Root divider ratio, applied on clock input to obtain root clock, to be used at next reconfiguration boundary. Input/ root frequency ratio is defined as  $2^{(CLKDIV-1)}$ .
  - The `SLIMBUS_DCT_CONFIG1_j[31]/SLIMBUS_DCR_CONFIG1_j[31]` ENABLE bit (this field is also cleared when the superframe or frame sync is lost): Data channel agent enabling control
  - The `SLIMBUS_DCT_CONFIG1_j[15]/SLIMBUS_DCR_CONFIG1_j[15]` CL bit: Channel link configuration mode selection
  - The `SLIMBUS_DCT_CONFIG1_j[26:20]/SLIMBUS_DCR_CONFIG1_j[26:20]` PR bit field: Presence rate configuration
  - The `SLIMBUS_DCT_CONFIG1_j[3:0]/SLIMBUS_DCR_CONFIG1_j[3:0]` TP bit field: Transfer protocol selection
  - The `SLIMBUS_DCT_CONFIG2_j[11:0]/SLIMBUS_DCR_CONFIG2_j[11:0]` SD bit field: Segment distribution
- The following register bits are cleared to 0. They correspond to features enabled for the upcoming reconfiguration boundary, and that are discarded here.
  - The `SLIMBUS_FR_CONTROL[1]` BUS\_RESET bit: Bus reset request control
  - The `SLIMBUS_FR_CONTROL[0]` BOOT bit: Initiate an active framer (clock source) boot sequence for the component when the component is default active framer.
  - The `SLIMBUS_FL_CONTROL[6]` BUS\_SHUTDOWN
  - `SLIMBUS_FL_CONTROL[0]` BOOT bit: Boot the component when not in active framer mode.
  - The `SLIMBUS_FL_CONTROL[4]` KILL\_SFS bit is set when the reconfiguration sequence terminates incorrectly (in that case the bit must be set after the clear-up). Forces immediate frame synchronization loss.
  - The `SLIMBUS_FL_CONTROL[7]` CLEAR\_RECONFIGURATION bit itself; that is, the bit never reads out 1.
  - The `SLIMBUS_FR_FRAMER_HANDBOVER[12]` HANDBOVER\_ENABLE bit: Enable framer handover, upon NEXT\_ACTIVE\_FRAMER(NCO,NCI) reception.
  - The `SLIMBUS_FR_CLOCK_PAUSE[0]` CLOCK\_PAUSE bit: Controls clock pause/restart
- The following bit fields do not change, although they are updated as part of the reconfiguration message sequence:
  - The `SLIMBUS_FR_FRAMER_HANDBOVER[11:0]` NCO\_NCI bit field: The value is don't care as long as `SLIMBUS_FR_FRAMER_HANDBOVER[12] HANDBOVER_ENABLE = 0`, and is overwritten if a new handover is scheduled.
  - The `SLIMBUS_FR_CLOCK_PAUSE[2:1]` TRT bit field: The value is don't care as long as `SLIMBUS_FR_CLOCK_PAUSE[0] CLOCK_PAUSE = 0`, and is overwritten if a new pause is scheduled.

#### 23.9.4.5 Data Channels (Ports) Management

Ports (contained in devices) are associated with data channels that connect several ports, typically one output port on a data source device and one or more inputs ports on a data sink device, over periodically scheduled data segments and using a given transfer protocol (TP).

### 23.9.4.5.1 Data input/output: manual mode

A data channel agent FIFO stores a whole number of FIFO words. A FIFO word is a chunk of data that contains the AUX and DATA information of one SLIMbus data segment, with the following properties:

- The FIFO word size minimum is 4 bits (one slot) in the current implementation, as defined in the MIPI SLIMbus standard 1.01.00; they are of little practical use.
- The FIFO word size maximum is 32 bits (eight slots) in the current implementation, equal to one physical FIFO RAM word and to one read/write access. Larger segment sizes (up to 31 slots = 124 bits) segments are defined in the MIPI SLIMbus standard version 1.01.00, but they are not implemented here.
- Between the minimum and maximum values, the FIFO word size is programmable, with a slot (that is, 4 bits) granularity.
- The AUX information is a field of 0, 1, or 2 slots (that is, 0, 4, or 8 bits) transmitted immediately before the DATA slots. All sizes are supported by current implementation. It is stored and managed along with the DATA by the module FIFOs.
- The DATA information is a field of 0 to 31 slots in the MIPI SLIMbus standard version 1.01.00, with slot granularity. This is implemented within the limits of the FIFO word size given previously, with AUX size + DATA size = FIFO word size; therefore, the DATA information is a field of 0 to 8 slots.
- The extended asynchronous transfer protocols (TP; that is, simplex and half-duplex) are exceptions to the previously discussed rules. In that case, the source device fills each segment with as many bytes as it deems necessary (provided it fits in the segment), and lets the sink device know how many through the TAG NVB field:
  - The source transmits as many whole FIFO words as it deems necessary. This implies that the FIFO word is a byte multiple (that is, an even number of 4-bit slots).
  - The sink receives a whole number of bytes, which it stores in byte-size FIFO words.
  - AUX is not applicable and is not supported in these modes.

Each read (or write) access to the appropriate [SLIMBUS\\_DCR\\_DATA\\_j](#) (respectively, [SLIMBUS\\_DCT\\_DATA\\_j](#)) removes (respectively, adds) one FIFO word from RX (TX) FIFO #N. [Table 23-670](#) lists examples of possible FIFO word mappings (with the AUX and DATA slots indicated as A() and D()) inside 32-bit read and write accesses.

**NOTE:** The transmission over the SLIMbus serial interface is always A(0) to A(N1), and then D(0) to D(N2); that is, MSB to LSB.

**Table 23-670. Examples of AUX + DATA Mapping in 32-bit Read/Write Accesses**

FIFO Format	Word	FIFO Word Size (in Slots)	32-bit Access Read/Write Data (Bit Range)									
			31..28	27..24	23..20	19..16	15..12	11..8	7..4	3..0		
4-bit + 0 aux		1 (min)									D(0)	
8-bit + 0 aux		2									D(0)	D(1)
12-bit + 0 aux		3								D(0)	D(1)	D(2)
16-bit + 0 aux		4							D(0)	D(1)	D(2)	D(3)
24-bit + 0 aux		6				D(0)	D(1)	D(2)	D(3)	D(4)	D(5)	
32-bit + 0 aux		8 (max)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)	D(6)	D(7)		
4-bit + 4 aux		2									A(0)	D(0)
24-bit + 4 aux		7			A(0)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)	
28-bit + 4 aux		8 (max)	A(0)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)	D(6)		
4-bit + 8 aux		3							A(0)	A(1)	D(0)	
24-bit + 8 aux		8 (max)	A(0)	A(1)	D(0)	D(1)	D(2)	D(3)	D(4)	D(5)		

### 23.9.4.5.2 Data Input/Output: DMA Request Mode

The DMA mode reuses all the features of the manual mode defined in [Section 23.9.4.5.1](#), but adds a DMA request generation mechanism to offload the data manipulation task to an external (off-module) DMA controller. As far as the FIFOs themselves are concerned, the accesses are unchanged. For more information about the DMA controller configuration see [Chapter 16](#), *SDMA*.

DMA data channels can be enabled by the [SLIMBUS\\_CMP\\_DMAENABLE\\_SET](#) register and disabled by the [SLIMBUS\\_CMP\\_DMAENABLE\\_CLR](#) register.

### 23.9.4.5.3 Data Channel Agent FIFO Control and Status

Each data channel agent is associated with a FIFO, fixed in either TX or RX direction. All TX FIFOs are mapped to a shared buffer space, all RX FIFOs to another shared buffer space. FIFO sizes are software-programmable.

A FIFO must be configured before the data channel is enabled, depending on system-related parameters. For instance, more or less FIFO depth may be required. More FIFO is desirable to prevent underflow/overflow errors in a jittery transmission, but may also carry an unacceptable latency penalty in a voice stream. In any case, FIFO depth is beyond the SLIMbus protocol.

### 23.9.4.6 FIFO Management

The SLIMbus controller includes two FIFOs, used to buffer transmit/receive data/messages. The SLIMBUS1 FIFO is 32 bytes for TX and 32 bytes for RX. The SLIMBUS2 FIFO is 64 bytes for TX and 64 bytes for RX. FIFO size information is given by the [SLIMBUS\\_CMP\\_HWINFO](#)[19:12] RRSZ and [11:4] TRSZ bit fields.

FIFOs are connected to SLIMbus-side agents, which transmit and receive data on the serial SLIMbus DATA line. All ports are synchronous to the SLIMbus clock. The numbers of data channel agents are given by [SLIMBUS\\_CMP\\_HWINFO](#)[27:24] TDC and [23:20] RDC bit fields.

A segment (see [Section 23.9.2.3.2](#)) passes through the internal RX and TX FIFOs, where it is stored in FIFO words. The size of the FIFO word, expressed in 4-bit slots, is configurable by software. The FIFO word size is hardware-calculated with the following parameters:

- The [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[9:5]/[SLIMBUS\\_DCT\\_CONFIG1\\_j](#)[9:5] SL bit field: Channel segment length, in slots
- The [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[14:10]/[SLIMBUS\\_DCT\\_CONFIG1\\_j](#)[14:10] DL bit field: Channel data length, integer
- The [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[3:0]/[SLIMBUS\\_DCT\\_CONFIG1\\_j](#)[3:0] TP (tag\_length) bit field: Length of segment TAG field, function of the channel transfer protocol, in slots.
- The [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[19:16]/[SLIMBUS\\_DCT\\_CONFIG1\\_j](#)[19:16] AF (aux\_length) bit field: Length of segment AUX field, function of the channel auxiliary format, in slots.

The FIFO word size is computed as follows by the module hardware:

- if DL is equal to 0, FIFO word size = SL tag\_length(TP)
- if DL is not equal to 0, FIFO word size = aux\_length(AF) + DL

#### 23.9.4.6.1 FIFO Mapping

Each FIFO must be mapped in a free zone of the shared buffer before enabling, as follows:

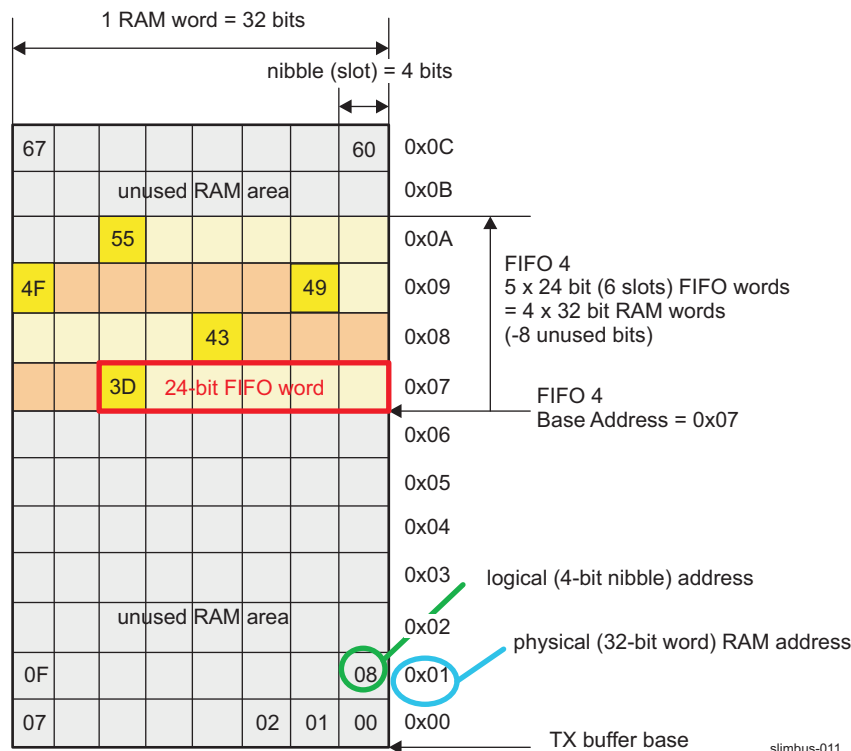

- The [SLIMBUS\\_DCR\\_FIFO\\_SETUP2\\_j](#)[7:0] SIZE and/or [SLIMBUS\\_DCT\\_FIFO\\_SETUP2\\_j](#)[7:0] SIZE + 1: Capacity of FIFO in FIFO words. (The minimum setting recommended by the SLIMbus protocol is 4-word deep.)
- The [SLIMBUS\\_SMT\\_FIFO\\_SETUP](#)[6:5] SIZE\_HI/[SLIMBUS\\_SMR\\_FIFO\\_SETUP](#)[6:5] SIZE\_HI and [SLIMBUS\\_SMT\\_FIFO\\_SETUP](#)[4:1] SIZE\_LO/[SLIMBUS\\_SMR\\_FIFO\\_SETUP](#)[4:1] SIZE\_LO bit fields: Capacity of shared TX/RX FIFOs, in bytes, minus 1.
- The [SLIMBUS\\_DCR\\_FIFO\\_SETUP1\\_j](#)[11:5] BASE\_ADDR and/or [SLIMBUS\\_DCT\\_FIFO\\_SETUP1\\_j](#)[11:5] BASE\_ADDR bit fields: RX and/or TX data channel agent FIFO base address within shared RX/TX RAM

- FIFO base nibble address = FIFO\_base\_physical\_add × 8
- FIFO top nibble address = FIFO\_base\_nibble\_add + (FIFO\_size × FIFO\_word\_size) – 1
- FIFO top physical address = FIFO\_top\_nibble\_add / 8
- The next base physical address available to map another FIFO is the current FIFO top physical address + 1.
- The shared RX and TX buffers are independent; that is, the RX and TX FIFOs are mapped to separate address spaces.

Figure 23-216 is an example mapping, with the following numerical configuration:

- Isochronous (SLIMBUS\_DCT\_CONFIG1\_4[3:0] TP = 0x0) TX FIFO using TX data channel agent 4
- FIFO word size: 6 slots = 24 bits, 20 DATA + 4 AUX (AF = 0xB, DL = 0x5)
- FIFO size: SLIMBUS\_DCT\_FIFO\_SETUP2\_4[7:0] SIZE = 4 (4 + 1 = 5 FIFO words stored in FIFO)
- FIFO base physical address: SLIMBUS\_DCT\_FIFO\_SETUP1\_4[11:5] BASE\_ADDR = 0x7 (= 7)
- FIFO base nibble address = 0x7 × 8 = 0x38 (56)
- FIFO top nibble address = 0x38 + (0x5 × 0x6) - 1 = 0x55 (= 85)
- FIFO top physical address = 0x55 / 0x8 = 0xA (= 10, this is a integer division)
- Next base physical address available to map another FIFO: 0xA + 1 = 0xB (= 11)

**Figure 23-216. Example of FIFO Mapping in Shared Buffer**

### 23.9.4.6.2 FIFO Status

The following receive-side status is available from the register fields:

- The `SLIMBUS_DCR_FIFO_STATUS_j[11:2]` RD\_LEVEL bit field: Number of FIFO words stored in RX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields range only from 0 to the FIFO size minus 1.
- The `SLIMBUS_DCR_FIFO_STATUS_j[0]` EMPTYbit: Active (1) status when RX FIFO #n contains 0 words (rd\_level = 0); otherwise, low (0). A read may cause an underflow.
- The `SLIMBUS_DCR_FIFO_STATUS_j[1]` HILEVEL bit: Active (1) status when FIFO (read) level is

(strictly) above the high threshold (that is, when there is more than a certain maximum of FIFO words stored in the FIFO). Equivalent to full in case `dma_hi_threshold = FIFO_size - 1` (the maximum allowed value).

Table 23-671 shows numerical examples for all valid DMA threshold values and all levels in an RX FIFO of `FIFO_size = 4` FIFO words (`SLIMBUS_DCR_FIFO_SETUP2_j[7:0] SIZE = 0x3`).

**NOTE:** The valid threshold range is from 0 to `FIFO_size - 1`: the case `threshold = FIFO_size` is functionally useless and impossible to program for maximum-sized FIFOs (because the `rd_level` field is 1 bit wider than the threshold fields).

**Table 23-671. HILEVEL/Empty Status of a 4-Word Receive FIFO, for all DMA Threshold Values**

rd_level (FIFO Words)	Empty	HILEVEL			
		thr = 0	thr = 1	thr = 2	thr = 3
0 (empty FIFO)	1	0	0	0	0
1	0	1	0	0	0
2	0	1	1	0	0
3	0	1	1	1	0
4 (full FIFO)	0	1	1	1	1

The following transmit-side status is available from the following bit fields:

- `SLIMBUS_DCT_FIFO_STATUS_j[11:2] WR_LEVEL`: Number of free FIFO words in TX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields range only from 0 to the FIFO size minus 1).
- `SLIMBUS_DCT_FIFO_STATUS_j[0] FULL`: Active (1) status when TX FIFO #n contains `FIFO_size` words (`wr_level = 0`); otherwise, low (0). A write may cause an overflow.
- `SLIMBUS_DCT_FIFO_STATUS_j[1] LOLEVEL`: Active (1) status when FIFO (write) level is under (or equal to) the low threshold; that is, when there is less than a certain minimum of free FIFO words in the FIFO. Equivalent to full in case `dma_lo_threshold = 0`.

Table 23-672 shows numerical examples for all valid DMA threshold values and all levels in a TX FIFO of `FIFO_size = 4` FIFO words (`SLIMBUS_DCT_FIFO_SETUP2_j[7:0] SIZE = 0x3`).

**NOTE:** The valid threshold range is from 0 to `FIFO_size - 1`: the case `threshold = FIFO_size` is functionally useless and impossible to program for maximum-sized FIFOs (because the `wr_level` field is 1 bit wider than the threshold fields).

**Table 23-672. LOLEVEL/Full Status of a 4-Word Transmit FIFO, for all DMA Threshold Values**

wr_level (FIFO Words)	Full	LOLEVEL			
		thr = 3	thr = 2	thr = 1	thr = 0
4 (empty FIFO)	1	1	1	1	0
3	0	1	1	1	0
2	0	0	1	1	0
1	0	0	0	1	0
0 (full FIFO)	0	0	0	0	1

### 23.9.4.6.3 FIFO Configuration

The bit fields used to configure the FIFOs are:

- `SLIMBUS_DCR_FIFO_SETUP1_j[11:5] BASE_ADDR` and/or `SLIMBUS_DCT_FIFO_SETUP1_j[11:5] BASE_ADDR`: RX and/or TX data channel agent FIFO base address within shared RX/TX RAM
- `SLIMBUS_DCR_FIFO_SETUP1_j[4:1] DMA_REQ_SIZE` and/or `SLIMBUS_DCT_FIFO_SETUP1_j[4:1]`

DMA\_REQ\_SIZE: DMA request size minus 1, in accesses

- [SLIMBUS\\_DCR\\_FIFO\\_SETUP2\\_j\[7:0\]](#) SIZE and/or [SLIMBUS\\_DCT\\_FIFO\\_SETUP2\\_j\[7:0\]](#) SIZE: Capacity of FIFO in FIFO words. (The FIFO can be 1-word deep [the minimum possible value], but it is not recommended. The minimum setting recommended by the SLIMbus protocol is 4-word deep).
- [SLIMBUS\\_DCR\\_FIFO\\_SETUP2\\_j\[15:8\]](#) SB\_TRESHOLD: SLIMbus-side RX data channel agent FIFO threshold, used for SLIMbus reception.
- [SLIMBUS\\_DCT\\_FIFO\\_SETUP2\\_j\[15:8\]](#) SB\_TRESHOLD: SLIMbus-side TX data channel agent FIFO threshold, used for SLIMbus transmission.
- [SLIMBUS\\_DCR\\_FIFO\\_SETUP2\\_j\[23:16\]](#) DMA\_TRESHOLD: Software-side RX data channel agent FIFO low threshold. DMA write requests stop when [SLIMBUS\\_DCR\\_FIFO\\_STATUS\\_j\[11:2\]](#) RD\_LEVEL goes under threshold.
- [SLIMBUS\\_DCT\\_FIFO\\_SETUP2\\_j\[23:16\]](#) DMA\_TRESHOLD: Software-side TX data channel agent FIFO low threshold. DMA write requests stop when [SLIMBUS\\_DCT\\_FIFO\\_STATUS\\_j\[11:2\]](#) WR\_LEVEL goes under threshold.
- [SLIMBUS\\_DCR\\_FIFO\\_SETUP2\\_j\[23:16\]](#) DMA\_TRESHOLD: Software-side RX data channel agent FIFO high threshold. DMA read requests start when [SLIMBUS\\_DCR\\_FIFO\\_STATUS\\_j\[11:2\]](#) RD\_LEVEL goes above threshold.
- [SLIMBUS\\_DCT\\_FIFO\\_SETUP2\\_j\[23:16\]](#) DMA\_TRESHOLD: Software-side TX data channel agent FIFO high threshold. DMA read requests start when [SLIMBUS\\_DCT\\_FIFO\\_STATUS\\_j\[11:2\]](#) WR\_LEVEL goes above threshold.
- [SLIMBUS\\_DCR\\_FIFO\\_STATUS\\_j\[0\]](#) EMPTY: Active (1) status when RX FIFO #n contains 0 words (rd\_level = 0), else low (0). A read may cause an underflow.
- [SLIMBUS\\_DCT\\_FIFO\\_STATUS\\_j\[0\]](#) FULL: Active (1) status when TX FIFO #n contains FIFO\_size words (wr\_level = 0), else low (0). A write may cause an overflow.
- [SLIMBUS\\_DCT\\_FIFO\\_STATUS\\_j \[1\]](#) LOLEVEL: Active (1) status when FIFO (write) level is under (or equal to) the low threshold, that is, when there is less than a certain minimum of free FIFO words in the FIFO. Equivalent to full in case dma\_lo\_threshold = 0.
- [SLIMBUS\\_DCR\\_FIFO\\_STATUS\\_j\[1\]](#) HILEVEL: Active (1) status when FIFO (read) level is (strictly) above the high threshold, that is, when there is more than a certain maximum of FIFO words stored in the FIFO. Equivalent to full in case dma\_hi\_threshold = FIFO\_size - 1 (the maximum allowed value).
- [SLIMBUS\\_DCR\\_FIFO\\_STATUS\\_j\[11:2\]](#) RD\_LEVEL: Number of FIFO words stored in RX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields only range from 0 to the FIFO\_size minus 1).
- [SLIMBUS\\_DCT\\_FIFO\\_STATUS\\_j\[11:2\]](#) WR\_LEVEL: Number of free FIFO words in TX FIFO #n. (This field is 1 bit longer than the size and threshold fields, because it ranges from 0 to the FIFO size, whereas the other fields only range from 0 to the FIFO\_size minus 1).

### 23.9.4.7 SLIMbus Transfer Protocols

Several registers are used to configure each Transfer Protocol. [Table 23-673](#) shows a description of these registers and fields.

**Table 23-673. Register Fields Used to Configure Transfer Protocols**

Register	Field	Description
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	Transfer protocol choice
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [4]	TP_QUALIFIER	Used only for asynchronous TPs (qualifier for plain/extended half-duplex asynchronous TPs)
<a href="#">SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	Used only for asynchronous TPs (qualifier for plain/extended half-duplex asynchronous TPs)
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	Total segment length (SL), in 4-bit slots, $SL \geq TAG \text{ length} + AUX \text{ length} + DATA \text{ length}$
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	4-MSB presence rate (PR). Selects the base frequency and the calculation mode of N, with: $PR = 2^N \times \text{base frequency}$ .
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	3-LSB presence rate (PR). Sets the multiple of the base frequency for the presence frequency.
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	Segment data length, in 4-bits slots. AUX+DATA length must fit in a FIFO word.
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	Enable/disable data channel
<a href="#">SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	Segment periodicity and offset (segment distribution)

#### 23.9.4.7.1 Isochronous Transfer Protocol

[Table 23-674](#) lists the register fields to program isochronous data transfer protocol.

**Table 23-674. Register Fields Used for Isochronous Transfer Protocol**

Register	Field	Value
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	0x0 (isochronous transfer protocol)
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	Unused in this mode
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	2 to 8, see
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	2 to 8, see
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	1 (enabled)
<a href="#">SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	Segment periodicity and offset

##### 23.9.4.7.1.1 Isochronous Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segmen offset and periodicity.

Isochronous has no explicit presence bit because data is always assumed to be present. The SL-slots segment is therefore always composed of the following elements:

- 0, 1, or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 31.
- 0 or more unused slots (should be 0, because this is wasted bandwidth)

**NOTE:**

- Maximum supported SL and DL are limited by the maximum FIFO word size (the actual implementation of the agent), because each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits):
  - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
  - SL range is 2 to 8 (= DL, since there is no TAG in isochronous protocol).
  - DL = 0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- DL = 0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
  - DL = 31 cannot be used with 1-slot AUX contents because 1 AUX slot + 31 DATA slots (DL) > 31 segment slots (SL max) (assuming no more FIFO word size limit)
  - DL = 30 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
  - ...

**23.9.4.7.2 Pushed Transfer Protocol**

Table 23-675 lists the register fields to program to have a pushed data transfer protocol.

**Table 23-675. Register Fields Used for Pushed Transfer Protocol**

Register	Field	Value
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	0x1 (pushed Transfer Protocol)
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [4]	TP_QUALIFIER	unused in this mode
<a href="#">SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	unused in this mode
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	3 to 9, see
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	2 to 8, see
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	N/A
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	1 (enabled)
<a href="#">SLIMBUS_DCR_CONFIG2_j</a> / <a href="#">SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	segment periodicity and offset

### 23.9.4.7.2.1 Pushed Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for STR, P control bits (Sample TRAnsmmit, Presence)
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present (P=0), all slots except the TAG are unused and undriven.

---

**NOTE:**

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
    - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
    - SL range is 3 to 9 (= DL + 1 TAG)
  - DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
  - Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
    - DL=31 cannot be used at all for pushed (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) > 31 segment slots (SL max).
    - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
    - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
    - ...
- 

### 23.9.4.7.3 Pulled Transfer Protocol

Table 23-676 lists the register fields to program to have a pulled data transfer protocol.

**Table 23-676. Register fields used for Pulled Transfer Protocol**

Register	Field	Value
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[3:0]	TP	0x2 (pulled Transfer Protocol)
SLIMBUS_DCR_CONFIG1_j[4]	TP_QUALIFIER	unused in this mode
SLIMBUS_DCT_CONFIG1_j[4]	TP_QUALIFIER	unused in this mode
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[9:5]	SL	3 to 9, see
SLIMBUS_DCR_CONFIG1_j[26:23]	PR_HI	N/A, only for information
SLIMBUS_DCR_CONFIG1_j[22:20]	PR_LO	N/A, only for information
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[14:10]	DL	2 to 8, see
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[15]	CL	N/A

**Table 23-676. Register fields used for Pulled Transfer Protocol (continued)**

Register	Field	Value
SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j[31]	ENABLE	1 (enabled)
SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j[11:0]	SD	segment periodicity and offset

#### 23.9.4.7.3.1 Pulled Segment Composition

Like for all other TPs, the TDM allocation of a pushed data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for SRQ, P control bits (Sample ReQuest, Presence)
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30.
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present (P=0), all slots except the TAG are unused and undriven.

#### NOTE:

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
  - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
  - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots.
- Not all combinations of legal field values are legal. The condition is that AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
  - DL=31 cannot be used at all for pushed (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) > 31 segment slots (SL max).
  - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
  - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
  - ...

#### 23.9.4.7.4 Asynchronous Transfer Protocol

Table 23-679 shows the configuration required for a (plain) asynchronous data channel agent, whether in simplex or in half-duplex mode.

One data channel requires one agent, except for 1/2 duplex where 2 agents are required (one in each direction).

**Table 23-677. "Plain" Asynchronous Endpoint Configurations**

Agent Setup	Type	TP	TP_qualifier	SD, SL, DL, ENABLE	Notes
TX simplex	TX	0x4 = "plain" asynchronous, simplex	0b0 = primary owner	independent	always primary owner
TX 1/2 duplex, primary	TX	0x5 = "plain" asynchronous, 1/2 duplex	0b0 = primary owner	same than RX (programming identical in both associated agent)	associated with RX agent
TX 1/2 duplex, secondary	TX	0x5 = "plain" asynchronous, 1/2 duplex	0b1 = secondary owner	same than RX (programming identical in both associated agent)	associated with RX agent
RX simplex	RX	0x4 = "plain" asynchronous, simplex	0b1 = secondary owner	independent	always secondary owner
RX 1/2 duplex, primary	RX	0x5 = "plain" asynchronous, 1/2 duplex	0b0 = primary owner	same than TX (programming identical in both associated agent)	associated with TX agent
RX 1/2 duplex secondary	RX	0x5 = "plain" asynchronous, 1/2 duplex	0b1 = secondary owner	same than TX (programming identical in both associated agent)	associated with TX agent

Table 23-680 lists the register fields to program to have a "plain" asynchronous transfer protocol.

**Table 23-678. Register fields used for "Plain" Asynchronous Transfer Protocol**

Register (for a given data channel agent)	Field	Value
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	0x4 (simplex) or 0x5 (half duplex)
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	primary or secondary ownership setup
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	3 to 9, see
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	Presence Rate, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	2 to 8, see
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	0 (disabled: makes no sense in asynchronous context)
<a href="#">SLIMBUS_DCR_CONFIG1_j / SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	1 (enabled)
<a href="#">SLIMBUS_DCR_CONFIG2_j / SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	segment periodicity and offset

#### 23.9.4.7.4.1 Asynchronous Segment Composition

Like for all other TPs, the TDM allocation of an asynchronous data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (2 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the SL-slots segment is composed of the following elements:

- 1 TAG slot for T1, T2, CTS, P control bits
- 0, 1 or 2 AUX slots, as defined by the 4-bit auxiliary format (AF) configuration field
- 2 to 8 DATA slots, as defined by the 5-bit data length (DL) configuration field. Full range defined by standard is 1 to 30.
- 0 or more unused slots. (should be 0, as this is wasted bandwidth)

When no data is present ( $P=0$ ), only the TAG slot is (partially) driven, depending on the ownership control and data flow control protocol phases. All other slots are unused and undriven.

**NOTE:**

- Maximum supported SL and DL are limited by the maximum FIFO word size (that is, the agent's actual implementation), as each segment (with data present) contains one FIFO word of DATA + AUX. In the current case, FIFO word size is 2 to 8 slots (8 to 32 bits), that is,
  - DL range is 2 to 8 (assuming no AUX slot, or AUX slots stored with the DATA in the FIFO)
  - SL range is 3 to 9 (= DL + 1 TAG)
- DL=0 is a special encoding where all slots after the AUX are considered to be DATA slots. In that case, there are by definition no unused slots. When used, the actual length of the segment data (in slots) is determined by hardware, by subtracting the TAG and AUX slots from the total segment length (SL). This case is strictly equivalent to the "direct" encoding, that is, where DL is a non-zero figure.
- Not all combinations of legal field values are legal, even in an ideal implementation. The condition is that TAG, AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
  - DL=31 cannot be used at all for asynchronous (although it is legal for other TPs) because 1 TAG slot + 31 DATA slots (DL) > 31 segment slots (SL max).
  - DL=30 cannot be used with 1-slot AUX contents (assuming no more FIFO word size limit)
  - DL=29 cannot be used with 2-slot AUX contents (assuming no more FIFO word size limit)
  - SL = 1 is forbidden, since the smallest asynchronous segment is 1 TAG slots + 1 DATA slot = 2 slots long.
  - ...

#### 23.9.4.7.4.2 Programming Specificities for Half-Duplex Protocol

Contrary to all other standard transfer protocols (TP), the half-duplex asynchronous ones (plain or extended) are bidirectional, that is, DATA slots can go in both directions. This means that 1 half-duplex asynchronous port (mapped on 1 half-duplex asynchronous data channel) uses 2 unidirectional data channel agents (FIFOs and logic) in the same controller.

The two agents are of opposite directions (1 TX + 1 RX), and the configuration register fields must always be programmed simultaneously and with matching values for both, so that both own the exact same slots (the data channel's allocated distribution).

#### 23.9.4.7.5 Extended Asynchronous Transfer Protocol

Table 23-679 shows the configuration required for an extended asynchronous data channel agent, whether in simplex or in half-duplex mode.

One data channel requires one agent, except for 1/2 duplex where 2 agents are required (one in each direction).

**Table 23-679. Extended Asynchronous Endpoint Configurations**

Agent Setup	Type	TP	TP_qualifier	SD, SL, DL, ENABLE	Notes
TX simplex	TX	0x6 = extended asynchronous, simplex	0b0 = primary owner	independent	always primary owner

**Table 23-679. Extended Asynchronous Endpoint Configurations (continued)**

Agent Setup	Type	TP	TP_qualifier	SD, SL, DL, ENABLE	Notes
TX 1/2 duplex, primary	TX	0x7 = extended asynchronous, 1/2 duplex	0b0 = primary owner	same than RX (programming identical in both associated agent)	associated with RX agent
TX 1/2 duplex, secondary	TX	0x7 = extended asynchronous, 1/2 duplex	0b1 = secondary owner	same than RX (programming identical in both associated agent)	associated with RX agent
RX simplex	RX	0x6 = extended asynchronous, simplex	0b1 = secondary owner	independent	always secondary owner
RX 1/2 duplex, primary	RX	0x7 = extended asynchronous, 1/2 duplex	0b0 = primary owner	same than TX (programming identical in both associated agent)	associated with TX agent
RX 1/2 duplex secondary	RX	0x7 = extended asynchronous, 1/2 duplex	0b1 = secondary owner	same than TX (programming identical in both associated agent)	associated with TX agent

The data length within the segment is now determined in the TAG NVB field, so that the SLIMbus data length (DL) parameter is not needed in the SLIMbus definition. The corresponding configuration register field [SLIMBUS\\_DCR\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCT\\_CONFIG1\\_j](#)[14:10] DL is still needed to set the FIFO word size: it must always be programmed to 0x2 (slots) = 1 byte, in both the data sinks and sources, which corresponds to the NVB granularity unit.

[Table 23-680](#) lists the register fields to program to have a "plain" asynchronous transfer protocol.

**Table 23-680. Register fields used for Extended Asynchronous Transfer Protocol**

Register (for a given data channel agent)	Field	Value
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [3:0]	TP	0x6 (simplex) or 0x7 (half duplex)
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [4]	TP_QUALIFIER	primary or secondary ownership setup
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [9:5]	SL	4 to 31, see
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [26:23]	PR_HI	Presence Rate, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> [22:20]	PR_LO	N/A, only for information
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [14:10]	DL	2: NVB data granularity (not the Slimbus "data length")
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [15]	CL	0 (disabled: makes no sense in asynchronous context)
<a href="#">SLIMBUS_DCR_CONFIG1_j</a> / <a href="#">SLIMBUS_DCT_CONFIG1_j</a> [31]	ENABLE	1 (enabled)
<a href="#">SLIMBUS_DCR_CONFIG2_j</a> / <a href="#">SLIMBUS_DCT_CONFIG2_j</a> [11:0]	SD	segment periodicity and offset

### 23.9.4.7.5.1 Extended Asynchronous Segment Composition

Like for all other TPs, the TDM allocation of an extended asynchronous data channel is composed of periodic segments of equal length, with the 5-bit segment length (SL) defining the reserved length, in slots (1 to 31), and the segment distribution (SD) defining the segment's offset and periodicity.

When data is present (P=1), the segment is composed of the following elements:

- 2 TAG slots for T1, T2, CTS, P control bits + 4-bit NVB field
- no (0) AUX slots. The current implementation does not support auxiliary fields in the extended

asynchronous TP, that is, the only legal value in the 4-bit auxiliary format (AF) is 0b0000. Other values are theoretically allowed by the SLIMbus standard, but for this TP they have little functional use.

- 0 to 28 DATA slots, as defined by the 4-bit number of valid bytes (NVB) field
- 0 or more unused slots. (this is wasted bandwidth, but as NVB can change for each segment this is normal)

When no data is present (P=0):

- 1st TAG slot is (partially) driven, depending on the ownership / data flow control protocol phases.
- 2nd TAG slot is either driven to all-zero, or undriven, that is, it always reads out as all-zero.
- All other slots are unused and undriven

---

**NOTE:**

- SL should be configured so that the maximum number of DATA slots is even, otherwise there will always be at least one unused slot.
  - Largest supported SL is not limited by the maximum FIFO word size (that is, the agent's actual implementation), unlike all other transfer protocols, as several FIFO words can be concatenated inside the same data segment.
  - Not all combinations of legal field values are legal. The condition is that TAG, AUX and DATA slots must fit within the allocated segment, that is, the sum must not be (strictly) greater than SL.
    - NVB = 15 (15 valid data bytes = 30 slots) cannot be used, because 2 TAG slots + 30 DATA slots (NVB x 2) = 32 > 31 segment slots (SL max).
    - SL = 1,2,3 are forbidden, since the smallest extended asynchronous segment is 2 TAG slots + 1 DATA byte (NVB = 1) = 4 slots long.
    - ...
- 

#### 23.9.4.7.5.2 Programming Specificities for Half-Duplex Protocol

Contrary to all other standard transfer protocols (TP), the half-duplex asynchronous ones (plain or extended) are bidirectional, that is, DATA slots can go in both directions. This means that 1 half-duplex asynchronous port (mapped on 1 half-duplex asynchronous data channel) uses 2 unidirectional data channel agents (FIFOs and logic) in the same controller.

The two agents are of opposite directions (1 TX + 1 RX), and the configuration register fields must always be programmed simultaneously and with matching values for both, so that both own the exact same slots (the data channel's allocated distribution).

#### 23.9.4.8 Paired-up channels

Two (or more) data channels with common properties can be paired up to operate in lockstep, for example, the left and right channels of a stereo audio flow: paired up data samples are generated together by a data source and need to arrive together at the data sink after going over the SLIMbus interface.

Assuming that pairing up has been implemented in both the sink and the source SLIMbus controllers of the data channel, it is enabled by configuring the channel as follows:

- Same segment windows: same channel rate, also expressed as segment interval (expressed in slots). This is encoded in the channel's Segment Distribution ([SLIMBUS\\_DCT\\_CONFIG2\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG2\\_j](#)[11:0] SD).
- Same Segment Length ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[9:5] SL)
- Segment offset (also encoded in SD) is necessarily different, otherwise the two channels would be scheduled in the same slots. SD is therefore different.
- Sequential Channel Numbers (CN) are assigned to the channels to be paired up
- Data channel numbering and scheduling are defined by the active manager device, through the broadcasts of the NEXT\_DEFINE\_CHANNEL() message.

Contents must be aligned, as follows:

- Same Transfer Protocol ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[3:0] TP). Asynchronous protocols (extended or not) do not support pairing.
- Same Aux Format ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[19:16] AF)
- Same Data Length ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[14:10] DL)
- Pairing can be enabled through the Channel Link ([SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[15] CL) data channel content bit. Pairing between channel #N-1 and channel #N is enabled by setting the Channel Link (CL) content bit to 1 on channel #N. For example, to pair up channels #1 and #2, CL = 1 in channel #2 (thus linking it to #1) and CL = 0 in channel #1 (thus keeping it separate from channel #0).
- Data channel contents are defined by active manager device, through the broadcasting of the NEXT\_DEFINE\_CONTENT() and CHANGE\_CONTENT() messages.

#### **23.9.4.8.1 Paired-up behaviour for Isochronous TP**

Data is by definition present in all segments, so that isochronous data channels with the same channel rate (as extracted from SD) are naturally paired up in normal operation. However, pairing also ensures that transmit underflows are also coupled:

- On the source side, if one of the channels has no data to transmit (TX underflow error, reported by IRQ) the other channels won't transmit any data either (even if they have some). This prevents the transmitter from getting out of sync.
- On the sink side, the underflow error will not be detected since no presence indication is transmitted, but the channels will remain in sync when the correct data flow resumes.

#### **23.9.4.8.2 Paired-up behaviour for Pushed TP**

Data presence in each segment is flagged by the STR/P bits (strobe/presence) driven by the data source in the TAG slot. On the source side, paired up channels must have the same P value in a given segment window, that is, data must only be transmitted (STR=P=1) when both channels have data to send. No requirements on the sink side.

#### **23.9.4.8.3 Paired-up behaviour for Pulled TP**

Data presence in a segment is requested by the SRQ TAG bit (sample request), driven by the sink, and confirmed by the P TAG bit (presence), driven by the source, so that SRQ and P are always equal in normal operation. The main pairing up requirement is therefore that the SRQ are aligned for all channel sinks, that is, that data is requested on all channels only if all sinks are ready to receive it, otherwise it is requested on none.

Pairing also ensures that transmit underflows are also coupled between channels: if for some reason a source cannot fulfill a request to drive data (SRQ=1, P=0: transmit underflow error, reported by IRQ), none of the other channels must drive data either, and all must flag P=0. The source side can only implement correct pairing if the sink side is correct in the first place; indeed, unless an underflow occurs, it is sufficient that the sink side implements pairing for the channels to be paired.

#### **23.9.4.9 Device and Addressing Management**

One of the manager device tasks is to keep track of devices present on the bus and to enumerate them, that is, assign a (different) Logical Address (LA) to each.

The manager device itself is implicitly enumerated by default, to Logical Address (LA) 0xFF. This is the only case where a device enumerates without ASSIGN\_LOGICAL\_ADDRESS message transmitted over the bus. Therefore for the manager device the following default configuration must be applied :

- [SLIMBUS\\_DEV\\_LA\\_i](#)[7:0] LA = 0xFF
- [SLIMBUS\\_DEV\\_LA\\_i](#)[8] LA\_ENABLE = 1
- [SLIMBUS\\_DEV\\_LA\\_i](#)[9] EA\_ENABLE = 1 (although manager is never addressed by Enumeration Address, EA)

The SLIMbus controller implements several devices, each of which is identified by its address. Addresses are used to exchange control messages over the shared message channel (SMC). The controller will recognize, store and respond (that is, acknowledge) to any message on the SMC targeted at one of the component's devices in the RX message FIFO.

The Enumeration Addresses (EA) composition is described in [Table 23-681](#), with:

- MI, PC and IV are Software-programmable and have the same value for all devices of the component with [SLIMBUS\\_CMP\\_MI\\_PC\[15:0\]](#) MI, [SLIMBUS\\_CMP\\_MI\\_PC\[31:16\]](#) PC and [SLIMBUS\\_CMP\\_IV\[7:0\]](#) IV.
- DI is hardwired and unique for each device within the component. It is given by [SLIMBUS\\_DCT\\_MAP\\_j / SLIMBUS\\_DCR\\_MAP\\_j\[7:0\]](#) DI bit field.
- Each device individual EA is Software-accessible, for reference, in read-only registers ([SLIMBUS\\_DEV\\_EA\\_LO\\_i](#) and [SLIMBUS\\_DEV\\_EA\\_HI\\_i](#) registers)

**Table 23-681. Enumeration Address (EA) makeup**

EA Subfield	Size (bits)	Top Bit	Bottom Bit	Source
MI: Manufacturer ID	16	47	32	<a href="#">SLIMBUS_CMP_MI_PC[15:0]</a> MI
PC: Product Code	16	31	16	<a href="#">SLIMBUS_CMP_MI_PC[31:16]</a> PC
DI: Device Index	8	15	8	hardwired
IV: Instance Value	8	7	0	<a href="#">SLIMBUS_CMP_IV[7:0]</a> IV
Total: EA	48	47	0	<a href="#">SLIMBUS_DEV_EA_HI_i / SLIMBUS_DEV_EA_LO_i</a>

The Logical Address (LA) assigned by the manager range from 0x00 to 0xEF, with the exception of the active manager located by definition at LA = 0xFF. It is configured through [SLIMBUS\\_DEV\\_LA\\_i\[7:0\]](#) LA for device m.

By default, a device uses a unique, static 48-bit Enumeration Address (EA). The EA is used only for enumeration, that is, the acquisition a dynamic Logical Address (LA) assigned by the active manager device.

---

**NOTE:** The port number is given by [SLIMBUS\\_DCT\\_MAP\\_j / SLIMBUS\\_DCR\\_MAP\\_j\[13:8\]](#) PN bit field.

---

## 23.9.4.10 Message Management

### 23.9.4.10.1 Transmission

#### 23.9.4.10.1.1 TX Message Sequence

The message transmission software sequence is the following:

- Initial state:
  - [SLIMBUS\\_SMT\\_CONTROL\[0\]](#) MESSAGE\_ENABLE = 0: No ongoing TX message. This also implies that TX message FIFO can receive another message.
  - [SLIMBUS\\_SMT\\_INFO\[5:0\]](#) = 0 : TX message event flags must be cleared (to 0) by Software by writing 1 to the corresponding bit(s). Failing to meet this condition will not prevent the message transmission, but will prevent a proper readout of the message transmission's outcome
  - Optional: If the IRQ method is to be used (instead of polling), it must be cleared and enabled, that is, [SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[2\]](#) SMT\_INFO\_EN = 1 and [SLIMBUS\\_CMP\\_IRQSTATUS\[2\]](#) SMT\_INFO = 0. For more information about interrupts see [Section 23.9.4.11](#).
- FIFO loading:
  - The message is written byte by byte to register [SLIMBUS\\_SMT\\_MESSAGE\[7:0\]](#). SLIMbus endianness is retained (big-endian) that is, serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.

- The minimum message size is 6 bytes (5 entered to the FIFO), for a short-arbitration (that is, logical source address LA = 1 byte), broadcast (that is, no destination address), no-payload message.
- The maximum theoretical message size is 39 bytes (38 entered to the FIFO), for a long-arbitration (that is, enumeration source address EA = 6 bytes), maximum remaining length (RL = 5b11111 = 31 bytes) message. The TX message FIFO can hold 32 bytes, that is, most messages (of 33 bytes or less).
- An overflow event is flagged ([SLIMBUS\\_SMT\\_INFO\[1\] OVERFLOW](#) is set) if too many bytes are written in. The TX message FIFO is then cleared before another TX message sequence attempt is made.
- Transmission enabling:
  - Once the message has been loaded into the TX message FIFO, software must write 1 on field [SLIMBUS\\_SMT\\_CONTROL\[0\] MESSAGE\\_ENABLE](#).
- Transmission:
  - From that point on, the device will attempt to transmit the message stored in the FIFO. Actual transmission may be delayed because of Message Sync acquisition time (if not already operational), Ongoing message on the SMC, and Arbitration(s) lost to higher-priority messages.
- Transmission completion and reporting:
  - Transmission is considered complete if one of the following -mutually exclusive- conditions is met, and the corresponding bit of [SLIMBUS\\_SMT\\_INFO](#) is set : Negative response [SLIMBUS\\_SMT\\_INFO\[3\] NACK = 1](#), or Positive response : [SLIMBUS\\_SMT\\_INFO\[2\] PACK = 1](#), or No response: [SLIMBUS\\_SMT\\_INFO\[4\] NORE = 1](#), or Illegal response: [SLIMBUS\\_SMT\\_INFO\[5\] UDEF = 1](#), or Transmit collision: [SLIMBUS\\_SMT\\_INFO\[0\] MC\\_TX\\_COL = 1](#).
  - If enabled ([SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[2\] SMT\\_INFO\\_EN = 1](#)), an interrupt request flag is set ([SLIMBUS\\_CMP\\_IRQSTATUS\[2\] SMT\\_INFO = 1](#)) and the IRQ line asserted.
  - Additionally, bit [SLIMBUS\\_SMT\\_CONTROL\[0\] MESSAGE\\_ENABLE](#) must auto-clear. Polling this bit will also work as an alternative to waiting for the IRQ.
  - Following the transmission, all message bytes have been removed from the TX message FIFO.

#### **23.9.4.10.1.2 TX Message FIFO Clearing**

The TX message FIFO must not be cleared as part of the normal message transmission operation, between messages. However, the clearing becomes necessary in case of error:

- FIFO overflow: the bit [SLIMBUS\\_SMT\\_INFO\[1\] OVERFLOW](#) is set
- FIFO underflow: the bit [SLIMBUS\\_SMR\\_INFO\[1\] UNDERFLOW](#) is set
- TX collision: the bit [SLIMBUS\\_SMT\\_INFO\[0\] MC\\_TX\\_COL](#) or the bit [SLIMBUS\\_SMR\\_INFO\[0\] MC\\_TX\\_COL](#) is set
- Undefined error condition, unknown FIFO content

Clearing is done by writing 0 to bit field [SLIMBUS\\_SMT\\_CONTROL\[0\] MESSAGE\\_ENABLE](#).

#### **23.9.4.10.2 Message reception**

##### **23.9.4.10.2.1 Message Responding**

The message responding and message receiving are separate but intertwined processes. Message responding starts as soon as a message is received, and consists in sending back information, including PACK or NACK.

##### **23.9.4.10.2.2 RX Message Sequence**

The message reception software sequence is the following:

- Initial state
  - [SLIMBUS\\_SMR\\_INFO](#) = 0x0: Pending (at 1) RX message event flags must be cleared (to 0) by Software by writing 1 to the corresponding bit(s).
  - Optional: If the IRQ method is to be used (instead of polling), it must be cleared and enabled, that

is, [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#)[3] SMR\_INFO\_EN = 1 and [SLIMBUS\\_CMP\\_IRQSTATUS](#)[3] SMR\_INFO = 0. For more information about interrupts see [Section 23.9.4.11](#)

- Message reception
  - Message reception requires no intervention: Messages with target addresses enabled in [SLIMBUS\\_DEV\\_LA\\_i](#) registers are automatically loaded into the RX message FIFO.
- FIFO unloading
  - The message is read byte by byte off the FIFO and put into register [SLIMBUS\\_SMR\\_MESSAGE](#)[7:0]. SLIMbus endianness is used (big-endian) that is, serial message starts with the MSB (bit 7) of the first byte written into the FIFO and ends with the LSB (bit 0) of the last written byte.
  - The minimum message size is 6 bytes, for a short-arbitration (that is, logical source address LA = 1 byte), broadcast (that is, no destination address), no-payload message.
  - The maximum theoretical message size is 39 bytes, for a long-arbitration (that is, enumeration source address EA = 6 bytes), maximum remaining length (RL = 5b11111 = 31 bytes) message. The RX message FIFO can hold 32 bytes, that is, most message types.
  - An overflow event is flagged ([SLIMBUS\\_SMR\\_INFO](#)[1] OVERFLOW bit is set) if too many bytes are received, which will overwrite previous bytes.
  - An underflow event is flagged ([SLIMBUS\\_SMR\\_INFO](#)[1] UNDERFLOW bit is set) if too many bytes are read out. The RX message FIFO is cleared before another RX message sequence attempt is made.
- Message decoding and servicing
  - This phase takes place in parallel with the unloading phase above. In some cases, a partial decoding can lead the software to skip the end of the unloading and flush the FIFO. The software will check Device Association (thanks to the [SLIMBUS\\_SMR\\_INFO](#)[2] RECEIVED\_MESSAGE bit) and Message Support.

#### 23.9.4.10.2.3 RX Message FIFO Clearing

- While the software is reading the message off the FIFO, the receive message agent unconditionally answers NACK, forcing remote side to retransmit any new incoming message.
- Only once the message has been read out of the FIFO, the software writes 1 on [SLIMBUS\\_SMR\\_INFO](#)[2] RECEIVED\_MESSAGE bit. This will automatically clear the FIFO.

The RX message FIFO is cleared as part of the normal message reception operation, between messages, although it is not strictly necessary. However, the clearing becomes compulsory in case of error:

- FIFO overflow: the bit [SLIMBUS\\_SMT\\_INFO](#)[1] OVERFLOW is set
- FIFO underflow: the bit [SLIMBUS\\_SMR\\_INFO](#)[1] UNDERFLOW is set
- Undefined error condition, unknown FIFO content

Clearing is done by writing 1 to register bit field [SLIMBUS\\_SMR\\_INFO](#)[2] RECEIVED\_MESSAGE bit.

#### 23.9.4.11 Interrupt Service Routines

This section lists specific software programming sequences, to be applied at specific phases of the SLIMbus protocol. This section covers the low-level software service of IRQs. More information about interrupts in the device can be found in [Chapter 17](#), *Interrupt Controllers*.

The SLIMbus controller has a single IRQ output line, controlled through 9-bit registers [SLIMBUS\\_CMP\\_IRQSTATUS](#), [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#) and [SLIMBUS\\_CMP\\_IRQENABLE\\_CLR](#). Each bit of this 1st level IRQ management points to a 2nd level information register. There are thus 9 such information registers, each connected with a specific submodule (framer device, interface device, message receiver, message transmitter, and one per generic data device).

2nd level information register and status register are written independently each other. When an event occurs, both bits are set to 1, and when the software writes 1 on either register the corresponding bit is cleared to 0. IRQ line is the status register output.

- When an event takes place, the corresponding 2nd level information bit must be set to 1 (if already 1: no change)
- When an event takes place, the corresponding 1st level IRQ status bit must be set to 1 (if enabled and if not already 1) and trigger an interrupt (if not already active). Note that this does not depend on the information bit's value: if the information bit is already high, the event must still potentially set the IRQ status bit.
- Writing 1 to a set IRQ status bit clears the bit and deasserts the IRQ line (if another status bit is set, the IRQ line will reassert immediately). Note that the clearing of the IRQ status does not depend on the information bit, that is, it will work even if the information bit has not been cleared.
- Writing 1 to a set information bit will clear the bit, but have no impact on the IRQ status

### CAUTION

The software sequence should always be as follows:

1. Clear the status bit
2. Read the relative information register
3. When needed and allowed, clear the information register

#### 23.9.4.11.1 Interrupt Requests

Table 23-682 lists the event flags, and their mask, that can cause module interrupts.

**Table 23-682. Interrupts**

Interrupt Line	Event Flag	Event Mask
SLIMBUS1_IRQ / SLIMBUS2_IRQ	SLIMBUS_CMP_IRQSTATUS_RAW[11:0] and SLIMBUS_CMP_IRQSTATUS[11:0]	SLIMBUS_CMP_IRQENABLE_SET[11:0] and SLIMBUS_CMP_IRQENABLE_CLR[11:0]

#### 23.9.4.11.2 Possible Interrupts

Table 23-683 lists all the interrupts that can occur and the related registers.

**Table 23-683. Event Summary**

Register	Field Name	Wake-Up Source	IE	Description
<b>Frame layer events</b>				
SLIMBUS_FL_INFO[6]	RECONFIGURED	Yes	No	Reconfiguration boundary crossed
SLIMBUS_FL_INFO[5]	SAW_BUS_RESET	Yes	No	Bus reset sequence detected on the bus
SLIMBUS_FL_INFO[3]	FOUND_MS	Yes	No	Message synchronization acquired
SLIMBUS_FL_INFO[2]	LOST_MS	Yes	Yes	Message synchronization lost
SLIMBUS_FL_INFO[1]	LOST_SFS	Yes	Yes	Superframe synchronization lost
SLIMBUS_FL_INFO[0]	LOST_FS	Yes	Yes	Frame synchronization lost
<b>Framer device events</b>				
SLIMBUS_FR_INFO[5]	CLOCK_RESTART	Yes	No	Clock restart request event detected
SLIMBUS_FR_INFO[4]	FRAMER_UNACTIVATED	Yes	Yes	Framer has left clock source operational state.
SLIMBUS_FR_INFO[3]	FRAMER_ACTIVATED	Yes	Yes	Framer has reached clock source operational state.
SLIMBUS_FR_INFO[2]	GC_TX_COL	Yes	Yes	Collision during guide byte transmit
SLIMBUS_FR_INFO[1]	FI_TX_COL	Yes	Yes	Collision during framing information transmit

**Table 23-683. Event Summary (continued)**

Register	Field Name	Wake-Up Source	IE	Description
SLIMBUS_FR_INFO[0]	FS_TX_COL	Yes	Yes	Collision during frame synchronization symbol transmit
<b>Shared message transmit channel events</b>				
SLIMBUS_SMT_INFO[7]	ABORT	Yes	No	TX message was aborted before completion because of message synchronization loss.
SLIMBUS_SMT_INFO[5]	UDEF	Yes	No	TX message has UDEF response: Undefined response, protocol error.
SLIMBUS_SMT_INFO[4]	NORE	Yes	No	TX message has NORE response: No or all-zero message response.
SLIMBUS_SMT_INFO[3]	NACK	Yes	No	TX message has NACK response: At least one of the recipient components requested message retransmission.
SLIMBUS_SMT_INFO[2]	PACK	Yes	No	TX message has PACK response: All recipient devices accepted the message.
SLIMBUS_SMT_INFO[1]	OVERFLOW	No	No	Overflow in TX message FIFO
SLIMBUS_SMT_INFO[0]	MC_TX_COL	Yes	Yes	Transmit collision in message channel during message transmission
<b>Shared message receive channel events</b>				
SLIMBUS_SMR_INFO[4]	OVERFLOW	Yes	No	Overflow in RX message FIFO. Message is larger than the FIFO.
SLIMBUS_SMR_INFO[3]	RECEIVED_RECONFIGUR E	Yes	No	RECONFIGURE_NOW() message received
SLIMBUS_SMR_INFO[2]	RECEIVED_MESSAGE	Yes	No	Message is available in the RX message FIFO.
SLIMBUS_SMR_INFO[1]	UNDERFLOW	No	No	Underflow in RX message FIFO. Software tried to read more bytes than available.
SLIMBUS_SMR_INFO[0]	MC_TX_COL	Yes	Yes	Transmit collision in message channel during message reception
<b>Data channel events</b>				
SLIMBUS_DCT_INFO_j[3]	LOLEVEL	Yes	No	Write level of TX data agent FIFO has gone above the threshold.
SLIMBUS_DCR_INFO_j[3]	HILEVEL	Yes	No	Read level of RX data agent FIFO has gone above the threshold.
SLIMBUS_DCT_INFO_j[2], SLIMBUS_DCR_INFO_j[2]	UNDERFLOW	Yes	No	Underflow in TX/RX data agent FIFO
SLIMBUS_DCT_INFO_j[1], SLIMBUS_DCR_INFO_j[1]	OVERFLOW	Yes	No	Overflow in TX/RX data agent FIFO
SLIMBUS_DCT_INFO_j[0], SLIMBUS_DCR_INFO_j[0]	DATA_TX_COL	Yes	Yes	TX collision in TX/RX data agent

### 23.9.4.11.3 Interface Device ISRs

The Interface Device ISRs are applied when a bit of status register [SLIMBUS\\_FL\\_INFO](#) is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS\[0\]](#) FL\_INFO and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[0\]](#) FL\_INFO\_EN. Service routines must be applied and the FL\_INFO bit field cleared (by writing 1 to it).

### **23.9.4.11.3.1 Lost Frame Synchronization (LOST\_FS)**

#### **23.9.4.11.3.1.1 Root Event**

This interrupt occurs when a loss of frame synchronization happens. All data channels automatically stop, that is, all active [SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[31] ENABLE bits are cleared. Component automatically reacquires frame, superframe and message synchronization.

#### **23.9.4.11.3.1.2 Interrupt Service Routine**

Frame synchronization (FS) loss implies the loss of higher-level superframe and message synchronizations:

- Messages cannot be expected to be transmitted / received until the component is operational again. Additionally, any ongoing reconfiguration sequence must be interrupted and made invalid by MS loss. No action required if no reconfiguration sequence is ongoing.
- Implicit superframe synchronization loss triggers a reset of all component ports: see [Section 23.9.4.4.3.6](#).

This field, [SLIMBUS\\_FL\\_INFO](#)[0] LOST\_FS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.11.3.2 Lost Superframe Synchronization (LOST\_SFS)**

#### **23.9.4.11.3.2.1 Root Event**

This interrupt occurs when a loss of superframe synchronization happens. The loss of lower-level frame synchronization also implies the loss of superframe synchronization, if already acquired, but does not trigger the assertion of LOST\_SFS Information Element. All data channels automatically stop, that is, all active [SLIMBUS\\_DCT\\_CONFIG1\\_j](#) / [SLIMBUS\\_DCR\\_CONFIG1\\_j](#)[31] ENABLE bits must be cleared. Component automatically reacquires superframe and message synchronization.

#### **23.9.4.11.3.2.2 Interrupt Service Routine**

Superframe synchronization (SFS) loss will trigger the reset of all ports of the component: see [Section 23.9.4.4.3.6](#).

Superframe synchronization loss implies the loss of message synchronization, that is, messages cannot be expected to be transmitted / received until the component is operational again. Additionally, any ongoing reconfiguration sequence must be interrupted and made invalid by MS loss. No action required if no reconfiguration sequence is ongoing.

This field, [SLIMBUS\\_FL\\_INFO](#)[1] LOST\_SFS, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.11.3.3 Lost Message Synchronization (LOST\_MS)**

#### **23.9.4.11.3.3.1 Root Event**

This interrupt occurs when a loss of message synchronization happens. The loss of either lower-level frame or superframe synchronization also implies the loss of message synchronization, if already acquired, but does not trigger the assertion of LOST\_MS Information Element. Component automatically reacquires message synchronization, by seeking for Guide Channel information.

#### **23.9.4.11.3.3.2 Interrupt Service Routine**

Any ongoing reconfiguration sequence must be interrupted and made invalid by the Message Synchronisation (MS) loss. No action required here if no reconfiguration sequence is ongoing.

This field, [SLIMBUS\\_FL\\_INFO\[2\] LOST\\_MS](#), is not cleared by software into the ISR. Instead, it stays set until the component receives a `REQUEST_CLEAR_INFORMATION` message by the remote manager, requiring to clear it (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.11.3.4 Found Message Synchronization (FOUND\_MS)**

#### **23.9.4.11.3.4.1 Root Event**

This interrupt occurs when acquisition of message synchronization. In that state, messages may be transmitted and received over the SMC.

#### **23.9.4.11.3.4.2 Interrupt Service Routine**

If MS is reacquired, following a previous `LOST_MS` event, then a `REPORT_INFORMATION` message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: `LOST_MS`

If MS is reacquired, following a previous `LOST_FS` event, then a `REPORT_INFORMATION` message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: `LOST_FS`

If MS is reacquired, following a previous `LOST_SFS` event, then a `REPORT_INFORMATION` message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: `LOST_SFS`

If MS is reacquired, following a previous `MC_TX_COL` event, then a `REPORT_INFORMATION` message must be transmitted, as follows:

- Source: interface device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: `MC_TX_COL`

If MS is reacquired, following a previous `UDEF` (Received undefined message response ) event, the message that caused `UDEF` must be retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

In any case, software must clear the field [SLIMBUS\\_FL\\_INFO\[3\] FOUND\\_MS](#). From that point on, any pending messages in the TX FIFO will be sent.

### **23.9.4.11.3.5 Reconfigured (RECONFIGURED)**

#### **23.9.4.11.3.5.1 Root Event**

This interrupt occurs when crossing of a reconfiguration boundary. In case of clock pause, where the SLIMbus clock stops at the boundary (1st rising edge of the new superframe), the bit (and therefore the IRQ) is asserted at the clock pause, not at the clock restart.

### **23.9.4.11.3.5.2 Interrupt Service Routine**

Completes the software-controller reconfiguration sequence. No reconfiguration must be applied to the control registers between the RECONFIGURE\_NOW reception and the reconfiguration boundary. A attempt by the manager to start a new reconfiguration sequence during that interval is an error.

In the case of framer release handover and/or root frequency change, the active framer must start using a new clock input selection at the reconfiguration boundary (as per register field [SLIMBUS\\_FR\\_CLOCK\\_SOURCE\[6:4\]](#) CLKSEL). All non-selected SLIMbus clock inputs of active framer components and all SLIMbus clock inputs for clock receiver components (inactive framers), and that may have been used until the boundary, can be turned off at that point.

Field [SLIMBUS\\_FL\\_INFO\[6\]](#) RECONFIGURED must be software cleared (by writing 1 to it).

### **23.9.4.11.4 Framer Device ISRs**

The Framer Device ISRs are applied when a bit of status register FR\_INFO is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS\[1\]](#) FR\_INFO and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[1\]](#) FR\_INFO\_EN. Service routines must be applied, and the fr\_info bit field cleared (by writing 1 to it). Some interrupt generating events are collisions, which occur when the framer detects on DATA line a different value than it's actively driving.

#### **23.9.4.11.4.1 Transmit Collision in Frame Sync Symbol (FS\_TX\_COL)**

##### **23.9.4.11.4.1.1 Root Event**

Transmit collision detected while driving the frame sync symbol (as active framer) of the framing channel.

##### **23.9.4.11.4.1.2 Interrupt Service Routine**

A REPORT\_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: FS\_TX\_COL

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

#### **23.9.4.11.4.2 Transmit Collision in Frame Sync Symbol (FI\_TX\_COL)**

##### **23.9.4.11.4.2.1 Root Event**

Transmit collision detected while driving the framing information (as active framer) of the framing channel.

##### **23.9.4.11.4.2.2 Interrupt Service Routine**

A REPORT\_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: FI\_TX\_COL

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.11.4.3 Transmit Collision in Guide Channel (GC\_TX\_COL)**

#### **23.9.4.11.4.3.1 Root Event**

Transmit collision detected while driving the guide byte (as active framer), that is, during the guide channel.

#### **23.9.4.11.4.3.2 Interrupt Service Routine**

A REPORT\_INFORMATION message must be transmitted, as follows:

- Sender: framer device
- Destination: SLIMbus manager device (LA = 0xFF)
- Information Element: GC\_TX\_COL

This field is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

### **23.9.4.11.4.4 Framer Device Activated (FRAMER\_ACTIVATED)**

#### **23.9.4.11.4.4.1 Root Event**

Acquisition of active framer role by the component. This event is only possible on bus boot (when default active framer) and incoming framer handover (when inactive framer).

#### **23.9.4.11.4.4.2 Interrupt Service Routine**

Assert software implemented ACTIVE\_FRAMER information element.

Field [SLIMBUS\\_FR\\_INFO](#)[4] FRAMER\_UNACTIVATED must be software cleared (by writing 1 to it).

The ACTIVE\_FRAMER information element's assertion does not trigger the transmission by the framer device of a REPORT\_INFORMATION message, since the information is already "publicized" by the framer handover process.

### **23.9.4.11.4.5 Framer Device Unactivated (FRAMER\_UNACTIVATED)**

#### **23.9.4.11.4.5.1 Root Event**

Loss of active framer role by the component. This event is only possible on bus shutdown and outgoing framer handover (when active framer).

#### **23.9.4.11.4.5.2 Interrupt Service Routine**

Deassert software-implemented ACTIVE\_FRAMER information element.

Field [SLIMBUS\\_FR\\_INFO](#)[3] FRAMER\_ACTIVATED must be software cleared (by writing 1 to it).

The ACTIVE\_FRAMER information element's deassertion does not trigger the transmission by the framer device of a REPORT\_INFORMATION message, since the information is already "publicized" by the framer handover process.

### **23.9.4.11.4.6 Restart After Clock Pause (CLOCK\_RESTART)**

#### **23.9.4.11.4.6.1 Root Event**

Transition detected on the DATA line during a clock pause, driven by any of the connected components and seen by the clock source (active framer) as a restart request. Note that this field is set for all clock restarts, even if the local framer is inactive.

#### **23.9.4.11.4.6.2 Interrupt Service Routine**

Field [SLIMBUS\\_FR\\_INFO](#)[5] CLOCK\_RESTART must be software cleared (by writing 1 to it).

---

**NOTE:** Restart event is a source of asynchronous wakeup.

---

#### **23.9.4.11.5 Shared Message Channel Transmit ISRs**

These ISRs are applied when a bit of status register SMT\_INFO is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS](#)[2] SMT\_INFO and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET](#)[2] SMT\_INFO\_EN. Service routines must be applied, and the fr\_info bit field cleared (by writing 1 to it)

#### **23.9.4.11.5.1 Transmit Collision in Message Body (MC\_TX\_COL)**

##### **23.9.4.11.5.1.1 Root Event**

Transmit collision detected while transmitting a message, that is, writing any subfield except message response (arbitration, header, payload, or message integrity). The device immediately (before next cell) stop transmission and the component automatically lose message synchronization. The message has to be sent again, once message synchronization has been regained.

##### **23.9.4.11.5.1.2 Interrupt Service Routine**

This field, [SLIMBUS\\_SMT\\_INFO](#)[0] MC\_TX\_COL, is not cleared by software into the ISR. Instead, it stays set until the component receives a REQUEST\_CLEAR\_INFORMATION message by the remote manager (Receiving a message implies of course that message synchronization has been restored in the mean time). Only at this point, software can apply the message and clear the designated field.

#### **23.9.4.11.5.2 TX Message FIFO Overflow (OVERFLOW)**

##### **23.9.4.11.5.2.1 Root Event**

Overflow occurs when too many bytes are written into the TX message FIFO by the software, either because the entered message is too long or because the FIFO still contains bytes from previous messages. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

##### **23.9.4.11.5.2.2 Interrupt Service Routine**

TX message FIFO must be cleared as explained in [Section 23.9.4.10.1.2](#).

Field [SLIMBUS\\_SMT\\_INFO](#)[1] OVERFLOW must be software cleared (by writing 1 to it).

Message transmission must resume normally.

#### **23.9.4.11.5.3 Received Positive Acknowledge Message Response (PACK)**

##### **23.9.4.11.5.3.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is PACK.

##### **23.9.4.11.5.3.2 Interrupt Service Routine**

No action required for this field: [SLIMBUS\\_SMT\\_INFO](#)[2] PACK. FIFO is now available for another message.

#### **23.9.4.11.5.4 Received Negative Acknowledge Message Response (NACK)**

##### **23.9.4.11.5.4.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is NACK.

##### **23.9.4.11.5.4.2 Interrupt Service Routine**

Current message must be eventually retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

Field [SLIMBUS\\_SMT\\_INFO](#)[3] NACK must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

#### **23.9.4.11.5.5 Received No Message Response (NORE)**

##### **23.9.4.11.5.5.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is NORE.

##### **23.9.4.11.5.5.2 Interrupt Service Routine**

Current message must be eventually retransmitted until it succeeds or until the retransmit maximum (fully managed by software) is reached.

Field [SLIMBUS\\_SMT\\_INFO](#)[4] NORE must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

#### **23.9.4.11.5.6 Received Undefined Message Response (UDEF)**

##### **23.9.4.11.5.6.1 Root Event**

Message written in the TX message FIFO was transmitted after unlimited, automatic arbitration retries, and removed from the FIFO. Received message response (MR) is UDEF, that is, one of several undefined MR codes that are not combinations of legal responses, implying that an error has taken place. Component loses message synchronization, and reacquires it automatically.

##### **23.9.4.11.5.6.2 Interrupt Service Routine**

Field [SLIMBUS\\_SMT\\_INFO](#)[5] UDEF must be software cleared (by writing 1 to it).

FIFO is available for another message, which can be the same or another one.

#### **23.9.4.11.5.7 TX Message FIFO Underflow (UNDERFLOW)**

##### **23.9.4.11.5.7.1 Root Event**

Underflow takes place when the message transmission logic attempts to read more bytes than the FIFO contains. The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

##### **23.9.4.11.5.7.2 Interrupt Service Routine**

TX message FIFO must be cleared as explained in [Section 23.9.4.10.1.2](#).

Field must be software-cleared (by writing 1 to it).

Message transmission must resume normally, making sure the error is not repeated.

### **23.9.4.11.6 Shared Message Channel Receive ISRs**

These ISRs are applied when a bit of status register SMR\_INFO is set, which also triggers the assertion of bit field [SLIMBUS\\_CMP\\_IRQSTATUS\[3\]](#) SMR\_INFO and of the IRQ line, when enabled in bit field [SLIMBUS\\_CMP\\_IRQENABLE\\_SET\[3\]](#) SMR\_INFO\_EN. Service routines must be applied, and the FR\_INFO bit field cleared (by writing 1 to it)

#### **23.9.4.11.6.1 Transmit Collision in Message Response (MC\_TX\_COL)**

##### **23.9.4.11.6.1.1 Root Event**

Transmit collision detected while receiving a message, that is, writing the message response subfield. The component automatically loses message synchronization, and eventually reacquires it.

##### **23.9.4.11.6.1.2 Interrupt Service Routine**

The field [SLIMBUS\\_SMR\\_INFO\[0\]](#) MC\_TX\_COL must not be unconditionally software cleared, as it implements a Boolean IE that can only be cleared under specific conditions (and together with the [SLIMBUS\\_SMT\\_INFO\[0\]](#) MC\_TX\_COL).

#### **23.9.4.11.6.2 RX Message FIFO Underflow (UNDERFLOW)**

##### **23.9.4.11.6.2.1 Root Event**

Underflow takes place when too many bytes are read out of the RX message FIFO by the software, because of an error when estimating the message length, as defined in [Section 23.9.4.10.2.2](#). The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

##### **23.9.4.11.6.2.2 Interrupt Service Routine**

RX message FIFO must be cleared as explained in [Section 23.9.4.10.2.3](#).

Field [SLIMBUS\\_SMR\\_INFO\[1\]](#) UNDERFLOW must be software-cleared (by writing 1 to it).

---

**NOTE:** This software error is not supposed to take place, since the message itself is assumed to be correct and could affect the correct running of the SLIMbus protocol, if the received message cannot be recovered.

---

#### **23.9.4.11.6.3 RX Message FIFO Overflow (OVERFLOW)**

##### **23.9.4.11.6.3.1 Root Event**

Overflow occurs when too many bytes are received into the RX message FIFO because the entered message is too long. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

##### **23.9.4.11.6.3.2 Interrupt Service Routine**

RX message FIFO must be cleared as explained in [Section 23.9.4.10.2.3](#).

Field must be software cleared (by writing 1 to it).

Message transmission must resume normally.

### 23.9.4.11.6.4 Message Received (*RECEIVED\_MESSAGE*)

#### 23.9.4.11.6.4.1 Root Event

A message has been received and checked by the hardware: target address matches a local device (LA or EA), message length is coherent with AT/RL fields, integrity is correct for both PI and MI, all target devices acknowledged the message (PACK MR transmitted and received).

#### 23.9.4.11.6.4.2 Interrupt Service Routine

Received message must be unloaded from RX message FIFO, parsed, and the appropriate action taken, as explained in [Section 23.9.4.10.2.2](#).

Field `SLIMBUS_SMR_INFO[2]` *RECEIVED\_MESSAGE* must be software cleared (by writing 1 to it). This will also clear the message FIFO and allow the local component to respond PACK to new incoming messages.

### 23.9.4.11.6.5 Reconfigure\_now Message Received (*RECEIVED\_RECONFIGURE*)

#### 23.9.4.11.6.5.1 Root Event

A message has been received as in *RECEIVED\_MESSAGE* event above, with the additional condition that it has been recognized by hardware as a *RECONFIGURE\_NOW()* message. Note that by the time the ISR is executed, the reconfiguration may have already taken place.

#### 23.9.4.11.6.5.2 Interrupt Service Routine

Field `SLIMBUS_SMR_INFO[3]` *RECEIVED\_CONFIGURE* must be software cleared (by writing 1 to it).

### 23.9.4.11.7 Data Channel Port ISRs

These ISRs are applied when a bit of a status register `SLIMBUS_DCT_INFO_j` and/or `SLIMBUS_DCR_INFO_j` is set, which also triggers the assertion of bit field `SLIMBUS_CMP_IRQSTATUS[11:4]` *DCT\_INFO\_j/DCR\_INFO\_j* and of the IRQ line, when enabled in bit field `SLIMBUS_CMP_IRQENABLE_SET[11:4]` *DCT/DCR\_INFO\_j*. Service routines must be applied, and the `SLIMBUS_DCT_INFO_j` and/or `SLIMBUS_DCR_INFO_j` bit fields cleared (by writing 1 to it).

### 23.9.4.11.7.1 Transmit Collision in Data Channel Port (*DATA\_TX\_COL*)

#### 23.9.4.11.7.1.1 Root Event

Transmit collision detected while writing to the considered data channel, in any of the TAG, AUX, or DATA fields. Note that transmit collisions are possible even for receive ports, as those port may also write some TAG cells (that is, for pulled TP), where transmit collisions are possible. The device must immediately (before next cell) stop writing to the bus, only resuming on next segment.

#### 23.9.4.11.7.1.2 Interrupt Service Routine

The *REPORT\_INFORMATION* message must be transmitted, from the port's stereo or voice device (that is, with that device's LA in source address of arbitration field), to the active manager (that is, with manager's target LA in header = 0xFF), and containing the information element (IE) of the same name (*DATA\_TX\_COL*).

The field `SLIMBUS_DCT_INFO_j[0]` *DATA\_TX\_COL* and/or `SLIMBUS_DCR_INFO_j[0]` *DATA\_TX\_COL* must not be unconditionally software cleared, as it implements a boolean IE that can only be cleared under specific conditions.

**23.9.4.11.7.2 Data Channel FIFO Overflow (OVERFLOW)****23.9.4.11.7.2.1 Root Event**

Overflow occurs when the data rate into the FIFO exceeds the data rate out of the FIFO for a sufficient amount of time, which can happen in both TX and RX ports. The state of the FIFO after an overflow event is undetermined, but the other FIFOs are unaffected.

**23.9.4.11.7.2.2 Interrupt Service Routine**

The SLIMbus protocol does not specify the handling of such an event. However, since data integrity cannot be guaranteed following an that event, stopping the channel is an option.

Field [SLIMBUS\\_DCT\\_INFO\\_j\[1\]](#) / [SLIMBUS\\_DCR\\_INFO\\_j\[1\]](#) OVERFLOW must be software cleared (by writing 1 to it).

**23.9.4.11.7.3 Data Channel FIFO Underflow (UNDERFLOW)****23.9.4.11.7.3.1 Root Event**

Overflow occurs when the data rate out of the FIFO exceeds the data rate into the FIFO for a sufficient amount of time, which can happen in both TX and RX ports. The state of the FIFO after an underflow event is undetermined, but the other FIFOs are unaffected.

**23.9.4.11.7.3.2 Interrupt Service Routine**

The SLIMbus protocol does not specify the handling of such an event. However, since data integrity cannot be guaranteed following an that event, stopping the channel is an option.

Field [SLIMBUS\\_DCT\\_INFO\\_j\[2\]](#) / [SLIMBUS\\_DCR\\_INFO\\_j\[2\]](#) UNDERFLOW must be software cleared (by writing 1 to it).

## 23.9.5 SLIMbus Programming Guide

### 23.9.5.1 SLIMbus Low-Level Programming Models

This section describes the low-level programming sequences for the configuration and use of the SLIMbus module. Because the SLIMbus protocol is implemented partly by hardware and partly by software in the current module, some higher-level procedures, such as sending and answering specific SLIMbus protocol messages, are mentioned for the sake of clarity.

#### 23.9.5.1.1 Global Initialization

##### 23.9.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the SLIMbus module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the SLIMbus module. See [Section 23.9.3, SLIMbus Integration](#), and [Section 23.9.2, SLIMbus Environment](#), for further information.

**Table 23-684. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The required SLIMbus clocks must be enabled. If the SLIMbus module does not contain the active frame, it receives its functional clock (SLIMbus clock) from the CLK pin. For a summary of the SLIMbus clocks, see <a href="#">Table 23-666</a> . See <a href="#">Chapter 3, Power, Reset, and Clock Management</a>
Control Module	Module specific pad multiplexing must be set in the control module. For more information about the module configuration, see <a href="#">Chapter 18, Control Module</a> .
(Optional) L4 Interconnect	For information about the L4-PER interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .
(Optional) INTC	Cortex-A9 MPU and DSP subsystem INTCs must be configured to enable the interrupt requests to the Cortex-A9 MPU or to the DSP subsystem.
(Optional) sDMA and/or aDMA	sDMA (aDMA) configuration must be done to enable the module DMA channel requests. See <a href="#">Chapter 16, sDMA</a> .

#### 23.9.5.1.1.2 SLIMbus Global Initialization

##### 23.9.5.1.1.2.1 SLIMbus Module Software Reset

This procedure brings the SLIMbus module to a known state.

**Table 23-685. SLIMbus Module Software Reset**

Step	Register/Bit Field/Programming Model	Value
Initiate a software reset.	SLIMBUS_CMP_SYSCONFIG[0] SOFTRESET	0x1
Wait until reset is finished.	SLIMBUS_CMP_SYSCONFIG[0] SOFTRESET	=0x0

##### 23.9.5.1.1.2.2 Power Management and Wake-Up Configuration

This procedure configures the idle mode for SLIMbus component. By definition, the target can handle read/write transactions as long as it is out of IDLE state.

**Table 23-686. SLIMbus Power Management**

Step	Register/Bit Field/Programming Model	Value
Configure the local power management.	SLIMBUS_CMP_SYSCONFIG[3:2] IDLEMODE	0x-
Turn on/off internal clock autogating.	SLIMBUS_CMP_SYSCONFIG[8] AUTOGATINGDISABLE	0x-

### 23.9.5.1.2 SLIMbus Component Boot

The component boot sequence is initiated when the component decides to join the bus.

#### 23.9.5.1.2.1 Clock Source Component Boot

This procedure performs component boot in clock source mode (the component contains the active framer of the given bus).

**Table 23-687. Clock Source Component Boot**

Step	Register/Bit Field/Programming Model	Value
Set the active-framer boot flag.	SLIMBUS_FR_CONTROL[0] BOOT	0x1
Select the subframe length and the control space width: subframe mode (SM).	SLIMBUS_FL_SM[4:0] SM	0x--
Select root/SLIMbus frequency ratio: clock gear (CG).	SLIMBUS_FL_CG[3:0] CG	0x-
Indicate the root frequency (RF) to the framer device.	SLIMBUS_FL_RF[3:0] RF	0x-
Select a source of the functional (SLIMbus) clock (See also , <i>SLIMbus Integration</i> ).	SLIMBUS_FR_CLOCK_SOURCE[6:4] CLKSEL	0x-
Select a root divider ratio to obtain the desired root frequency (RF).	SLIMBUS_FR_CLOCK_SOURCE[3:0] CLKDIV	0x-
Initiate reconfiguration.	SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE	0x1
Wait for reconfiguration to finish.	SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE	=0x0

#### 23.9.5.1.2.2 Clock Receiver Component Boot

This procedure boots the SLIMbus when the component is in clock receiver mode (inactive framer).

**Table 23-688. Clock Receiver Component Boot**

Step	Register/Bit Field/Programming Model	Value
Set inactive-framer boot flag.	SLIMBUS_FL_CONTROL[0] BOOT	0x1
Initiate reconfiguration.	SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE	0x1
Wait for reconfiguration to finish.	SLIMBUS_FL_CONTROL[2] FORCE_RECONFIGURE	=0x0

#### 23.9.5.1.3 Data Agent Assignment

Before a SLIMbus device enumeration, it is assumed to have a given number of ports, and each port a given set of properties. Software must keep a data port table, updated by various events including SLIMbus resets, data channel config messages, and some reconfiguration messages.

At least one data agent (which implements the data ports in hardware) must be assigned to a SLIMbus device before it can receive/transmit actual payload data. The following settings must be done to configure the SLIMbus module.

**Table 23-689. Data Agent Assignment**

Step	Register/Bit Field/ Programming Model	Value
Set the port number (PN) for TX and/or RX data agent j. Must be unique within the device that it is mapped to..	SLIMBUS_DCT_MAP_j[13:8] PN SLIMBUS_DCR_MAP_j[13:8] PN	0x--
Set the index of the device (DI) TX and or RX data agent j belongs to.	SLIMBUS_DCT_MAP_j[7:0] DI SLIMBUS_DCR_MAP_j[7:0] DI	0x--
Validate settings.	SLIMBUS_FL_CONTROL [8] VALIDATE_DCMAP	0x1

### 23.9.5.1.4 Device Enumeration

Device enumeration is an acquisition of a dynamic logical address (LA) assigned by the active manager device. The LA ranges from 0x00 to 0xEF, with the exception of the active manager itself, located by definition at LA = 0xFF.

#### 23.9.5.1.4.1 Manager Device Enumeration

This procedure performs an manager device enumeration when the local manager device is the bus active manager.

**Table 23-690. Manager Device Enumeration**

Step	Register/Bit Field/Programming Model	Value
Wait for message synchronization.	SLIMBUS_FL_INFO [3] FOUND_MS	=0x1
Explicitly enumerate the device as active manager device.	SLIMBUS_DEV_LA_i[7:0] LA SLIMBUS_DEV_LA_i[8] LA_ENABLE SLIMBUS_DEV_LA_i[9] EA_ENABLE	0xFF 0x1 0x1

#### 23.9.5.1.4.2 Non-Manager Device Enumeration

This procedure is used when a non-manager device decides to participate on the bus. When the SLIMbus module contains the active manager, software must also perform the manager-side actions.

**Table 23-691. Non-Manager Device Enumeration**

Step	Register/Bit Field/Programming Model	Value
Enable the device to receive broadcast messages.	SLIMBUS_DEV_LA_i[9] EA_ENABLE	0x1
Wait for message synchronization or for REQUEST_SELF_ANNOUNCEMENT() message from active manager.	SLIMBUS_FL_INFO [3] FOUND_MS or see Section 23.9.5.1.6, <i>SLIMbus Transfer Procedures</i> .	=0x1
Send REPORT_PRESENT() message to the active manager (LA = 0xFF).	See Section 23.9.5.1.6, <i>SLIMbus Transfer Procedures</i> .	
Wait for ASSIGN_LOGICAL_ADDRESS(LA) message from the active manager.	See Section 23.9.5.1.6, <i>SLIMbus Transfer Procedures</i> .	
Extract the LA from the message and set it in the hardware.	SLIMBUS_DEV_LA_i[7:0] LA SLIMBUS_DEV_LA_i[8] LA_ENABLE	0x-- 0x1

### 23.9.5.1.5 Operational Modes Configuration

#### 23.9.5.1.5.1 SLIMbus Transfer Protocol Configuration

This procedure configures the data channel(s) for a specific transfer protocol use. It is assumed that at this moment the required channels are connected by means of CONNECT\_SOURCE(PN,CN) and CONNECT\_SINK(PN,CN) messages. No action on hardware is required after receiving these messages, except for the standard checks and clearing of the message FIFO. The channel numbers (CN) are kept and handled by software. The steps listed are required from the configured side, but if the local component contains the active manager software must also perform the configuration steps. Changing the order of NEXT\_\* messages is allowed.

**Table 23-692. SLIMbus Transfer Protocol Configuration**

Step	Register/Bit Field/Programming Model	Value
Wait for BEGIN_RECONFIGURATION() message.		
Clear reconfiguration parameters.	SLIMBUS_FL_CONTROL [7] CLEAR_RECONFIGURATION	0x1
Wait for NEXT_DEFINE_CHANNEL(CN, TP, SD, SL) message.	See Section 23.9.5.1.6, <i>SLIMbus Transfer Procedures</i> .	

**Table 23-692. SLIMbus Transfer Protocol Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Extract and set in hardware the transfer protocol (TP) for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG1_j[3:0] TP SLIMBUS_DCT_CONFIG1_j[3:0] TP	0x-
Extract and set in hardware the segment distribution (SD) for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG2_j[11:0] SD SLIMBUS_DCT_CONFIG2_j[11:0] SD	0x--
Extract and set in hardware the segment length (SL) for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG1_j[9:5] SL SLIMBUS_DCT_CONFIG1_j[9:5] SL	0x--
IF: Transfer protocol is asynchronous simplex	TP	=0x4 or =0x6
Set secondary owner if data agent j is RX or set primary owner if data agent j is TX.	SLIMBUS_DCR_CONFIG1_j[4] TP_QUALIFIER SLIMBUS_DCT_CONFIG1_j[4] TP_QUALIFIER	0x1 0x0
ELSEIF: Asynchronous half-duplex	TP	=0x5 or =0x7
Set ownership for data channel (combines one TX and one RX data agent).	SLIMBUS_DCR_CONFIG1_j[4] TP_QUALIFIER SLIMBUS_DCT_CONFIG1_j[4] TP_QUALIFIER	0x-
ENDIF		
Wait for NEXT_DEFINE_CONTENT(CN, FL, PR, AF, DT, CL, DL) message.	See <a href="#">Section 23.9.5.1.6</a> , <i>SLIMbus Transfer Procedures</i> .	
Extract and set in hardware the number of AUX slots in a segment for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG1_j[19:16] AF SLIMBUS_DCT_CONFIG1_j[19:16] AF	0x--
IF: Data type (DT) extracted from message is LPCM audio	DT	=0x1
Enable unsigned-to-OSAM encoding for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG1_j[28] DT_LPCM SLIMBUS_DCT_CONFIG1_j[28] DT_LPCM	0x1
ELSE		
Disable unsigned-to-OSAM encoding for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG1_j[28] DT_LPCM SLIMBUS_DCT_CONFIG1_j[28] DT_LPCM	0x0
ENDIF		
Extract and set in hardware the channel link bit (CL) for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG1_j[15] CL SLIMBUS_DCT_CONFIG1_j[15] CL	0x-
Extract and set in hardware the AUX + data length (DL) for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_CONFIG1_j[14:10] DL SLIMBUS_DCT_CONFIG1_j[14:10] DL	0x--
Perform the data FIFO(s) setup for RX and/or TX data agent(s).	See <a href="#">Section 23.9.5.1.5.2</a> , <i>SLIMbus Data FIFO Mapping and Setup</i> .	
Wait for NEXT_ACTIVATE_CHANNEL() message.	See <a href="#">Section 23.9.5.1.6</a> , <i>SLIMbus Transfer Procedures</i> .	
Request enabling of RX data agent j and/or of TX data agent j.	SLIMBUS_DCR_CONFIG1_j[31] ENABLE SLIMBUS_DCT_CONFIG1_j[31] ENABLE	0x1
Wait for RECONFIGURE_NOW() message.	See <a href="#">Section 23.9.5.1.6</a> , <i>SLIMbus Transfer Procedures</i> .	
This message is hardware-decoded and executed. No software action on the module is required except for emptying the FIFO to allow receiving of further messages.	SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE [3] RECEIVED_CONFIGURE	0x1

### 23.9.5.1.5.2 SLIMbus Data FIFO Mapping and Setup

This procedure maps each used FIFO to a free zone of the shared buffer. It also sets the FIFO thresholds used to trigger loading and unloading the FIFOs. These settings depend on the available free space, segment word length, and required FIFO depth. Thus, at this moment, the protocol type must be known and the data agent must not be enabled.

**Table 23-693. SLIMbus Data FIFO Mapping and Setup**

Step	Register/Bit Field/Programming Model	Value
Set the capacity ( in segment words) of data FIFO for RX agent j and/or for TX data agent j.	SLIMBUS_DCR_FIFO_SETUP2_j[7:0] SIZE SLIMBUS_DCT_FIFO_SETUP2_j[7:0] SIZE	0x--
Set the FIFO base address within shared RAM for RX agent j and/or for TX data agent j.	SLIMBUS_DCR_FIFO_SETUP1_j[11:5] BASE_ADDR SLIMBUS_DCT_FIFO_SETUP1_j[11:5] BASE_ADDR	0x--
Set SLIMbus-side FIFO threshold for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_FIFO_SETUP2_j[15:8] SB_THRESHOLD SLIMBUS_DCT_FIFO_SETUP2_j[15:8] SB_THRESHOLD	0x--
Set software-side FIFO threshold for RX data agent j and/or for TX data agent j.	SLIMBUS_DCR_FIFO_SETUP2_j[23:16] DMA_THRESHOLD SLIMBUS_DCT_FIFO_SETUP2_j[23:16] DMA_THRESHOLD	0x--
Bring the FIFO to empty state: RX data agent j and/or TX data agent j.	SLIMBUS_DCR_FIFO_SETUP1_j[0] FIFO_CLEAR SLIMBUS_DCT_FIFO_SETUP1_j[0] FIFO_CLEAR	0x1
Wait for clearing to complete.	SLIMBUS_DCR_FIFO_SETUP1_j[0] FIFO_CLEAR SLIMBUS_DCT_FIFO_SETUP1_j[0] FIFO_CLEAR	=0x0

### 23.9.5.1.6 SLIMbus Transfer Procedures

This section describes the low-level programming steps for message and data reception and transmission. For more information about message syntax, see the *MIPI Alliance Specification for SLIMbus Version 1.01.00*.

#### 23.9.5.1.6.1 Transmitting Message, Polling Mode

This procedure transmits a message over the SLIMbus without the use of interrupts.

**Table 23-694. Message Transmit Procedure, Polling Method**

Step	Register/Bit Field/Programming Model	Value
Wait if an ongoing TX message is still in progress.	SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE	=0x0
Clear TX message event flags.	SLIMBUS_SMT_INFO[7:0]	0xBF
Load the whole message byte-by-byte, except for the last one. That is, message integrity (MI) and response (MR), which are handled by hardware. The primary integrity (PI) field is computed and overwritten by hardware; thus, write any value for PI. The message cannot be larger than the FIFO size.	SLIMBUS_SMT_MESSAGE[7:0]	0x--
Initiate the transmit sequence.	SLIMBUS_SMT_CONTROL[0] MESSAGE_ENABLE	0x1
Check the message outcome by polling the information register bits. Process the event as described in <a href="#">Section 23.9.5.1.7, Event Handling</a> .	SLIMBUS_SMT_INFO Negative response: [3] NACK Positive response: [2] PACK No response: [4] NORE Illegal response: [5] UDEF FIFO overflow: [1] OVERFLOW Transmit collision: [0] MC_TX_COL Message sync loss: [7] ABORT	=0x1

#### 23.9.5.1.6.2 Transmitting Message, Interrupt Mode

This procedure transmits a message over the SLIMbus with interrupts enabled.

**Table 23-695. Message Transmit Procedure, Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Enable the shared-message-channel transmit interrupts.	SLIMBUS_CMP_IRQENABLE_SET[2] SMT_INFO_EN	0x1
Clear the interrupt status bit.	SLIMBUS_CMP_IRQSTATUS [2] SMT_INFO	0x1
The procedure continues without difference from polling mode. The exception is that if any info bit is set, it triggers an interrupt. The interrupt-service-routine then checks which info bit is set.	See <a href="#">Section 23.9.5.1.6.1, Transmitting Message, Polling Mode</a> .	

#### 23.9.5.1.6.3 Receiving Message, Polling Mode

This procedure reads a received in FIFO message without using interrupts.

**Table 23-696. Message Receive Procedure, Polling Method**

Step	Register/Bit Field/Programming Model	Value
Check for a received message.	SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE	=0x1
IF: Message is RECONFIGURE_NOW()	SLIMBUS_SMR_INFO[3] RECEIVED_RECONFIGURE	=0x1
RECONFIGURE_NOW() is hardware-decoded and executed. Software is required only to allow further message reception.	SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE SLIMBUS_SMR_INFO[3] RECEIVED_RECONFIGURE	0x1
ELSE		

**Table 23-696. Message Receive Procedure, Polling Method (continued)**

Step	Register/Bit Field/Programming Model	Value
Read the message byte-by-byte and decode it in parallel. The message size is determined from the message itself, from the arbitration type (AT) and remaining length (RL) fields. Read until message end is reached: (2 bytes if AT = 0xF, or 7 bytes if AT = 0x5) + 1 byte + RL bytes	SLIMBUS_SMR_MESSAGE[7:0]	0x-
Optionally, software can check for FIFO underflow event after every read out. Last byte then must be ignored. The event flag must be cleared by writing 0x1 to it.	SLIMBUS_SMR_INFO[1] UNDERFLOW SLIMBUS_SMR_INFO[1] UNDERFLOW	=0x1 0x1
Allow further message reception.	SLIMBUS_SMR_INFO[2] RECEIVED_MESSAGE	0x1
ENDIF		

**23.9.5.1.6.4 Receiving Message, Interrupt Mode**

This procedure reads the received in FIFO message by using interrupts.

**Table 23-697. Message Receive, Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Enable the shared-message-channel receive interrupts.	SLIMBUS_CMP_IRQENABLE_SET[3] SMR_INFO_EN	0x1
Clear the interrupt status bit.	SLIMBUS_CMP_IRQSTATUS [3] SMR_INFO	0x1
Wait for SMR_INFO interrupt.		
Clear the interrupt status bit.	SLIMBUS_CMP_IRQSTATUS [3] SMR_INFO	0x1
The procedure continues without difference from polling mode. The exception is that any set info bit triggers an interrupt. The interrupt-service-routine then checks to determine which event occurred.	See Section 23.9.5.1.6.3, <i>Receiving Message, Polling Mode</i> .	

**23.9.5.1.6.5 Receiving Data**

This procedure reads actual payload data off the FIFO. The data is read one data segment at a time (AUX + data) with no packing mode. Packing allows several small segments to be fit in a single FIFO access. Packing mode is selected through the SLIMBUS\_DCR\_FIFO\_SETUP2\_j[31] PACKING bit field.

**Table 23-698. Receiving Data, Polling Method**

Step	Register/Bit Field/Programming Model	Value
Wait for SLIMBUS_DCR_FIFO_SETUP2_j[23:16] DMA_THRESHOLD number of segment words to be available in FIFO.	SLIMBUS_DCR_FIFO_STATUS_j [1] HILEVEL	=0x1
Read SLIMBUS_DCR_FIFO_SETUP2_j[23:16] DMA_THRESHOLD segment words from FIFO.	SLIMBUS_DCR_DATA_j	See <sup>(1)</sup> .
Additionally, software can check whether no more segments are available to read.	SLIMBUS_DCR_FIFO_STATUS_j [0] EMPTY	=0x1

<sup>(1)</sup> Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

The following procedure uses an interrupt method to receive data.

**Table 23-699. Receiving Data, Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Enable the data receive interrupt. Write 0x1 for the required data agent.	<a href="#">SLIMBUS_CMP_IRQENABLE_SET</a>	0x1
Clear the corresponding interrupt status bit.	<a href="#">SLIMBUS_CMP_IRQSTATUS</a>	0x1
Wait for interrupt.		
Check the high-level info bit.	<a href="#">SLIMBUS_DCR_INFO_j[3] HILEVEL</a>	=0x1
Clear the interrupt status bit of the data agent.	<a href="#">SLIMBUS_CMP_IRQSTATUS</a>	0x1
Read <a href="#">SLIMBUS_DCR_FIFO_SETUP2_j[23:16]</a> DMA_THRESHOLD segment words from FIFO.	<a href="#">SLIMBUS_DCR_DATA_j</a>	See <sup>(1)</sup>
Additionally, software can check whether no more segments are available to read.	<a href="#">SLIMBUS_DCR_FIFO_STATUS_j [0] EMPTY</a>	=0x1
Clear the high-level info bit.	<a href="#">SLIMBUS_DCR_INFO_j[3] HILEVEL</a>	0x1

<sup>(1)</sup> Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

This procedure enables DMA request generation to the sDMA or aDMA engine, which must be configured in advance. DMA request starts whenever the threshold condition is met. DMA request stops after a certain number of nonempty read accesses to the FIFO are complete. This size typically corresponds to a DMA burst and in the [SLIMBUS\\_DCR\\_FIFO\\_SETUP1\\_j\[4:1\] DMA\\_REQ\\_SIZE](#) bit field.

**Table 23-700. Receiving Data, DMA Enable**

Step	Register/Bit Field/Programming Model	Value
Set DMA request size (for precise DMA mode).	<a href="#">SLIMBUS_DCR_FIFO_SETUP1_j[4:1] DMA_REQ_SIZE</a>	0x-
Enable the data receive DMA requests. Write 0x1 for the required RX data agent.	<a href="#">SLIMBUS_CMP_DMAENABLE_SET</a>	0x1

### 23.9.5.1.6.6 Transmitting Data

This procedure loads actual payload data into the FIFO. The data is loaded one data segment at a time (AUX + data), when packing mode is not used. Packing allows several small segments to be fit into a single FIFO access. Packing mode is selected through the [SLIMBUS\\_DCT\\_FIFO\\_SETUP2\\_j\[31\] PACKING](#) bit field.

**Table 23-701. Transmitting Data, Polling Method**

Step	Register/Bit Field/Programming Model	Value
Wait for <a href="#">SLIMBUS_DCT_FIFO_SETUP2_j[23:16]</a> DMA_THRESHOLD number of free segment words.	<a href="#">SLIMBUS_DCT_FIFO_STATUS_j [1] LOLEVEL</a>	=0x1
Write <a href="#">SLIMBUS_DCR_FIFO_SETUP2_j[23:16]</a> DMA_THRESHOLD segment words to FIFO.	<a href="#">SLIMBUS_DCT_DATA_j</a>	See <sup>(1)</sup>
Additionally, software can check whether no more FIFO space is available to write.	<a href="#">SLIMBUS_DCT_FIFO_STATUS_j [0] FULL</a>	=0x1

<sup>(1)</sup> Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

The following procedure uses an interrupt method to transmit data.

**Table 23-702. Transmitting Data, Interrupt Method**

Step	Register/Bit Field/Programming Model	Value
Enable the data transmit interrupt. Write 0x1 for the required data agent.	<a href="#">SLIMBUS_CMP_IRQENABLE_SET</a>	0x1
Clear the corresponding interrupt status bit.	<a href="#">SLIMBUS_CMP_IRQSTATUS</a>	0x1
Wait for interrupt.		

**Table 23-702. Transmitting Data, Interrupt Method (continued)**

Step	Register/Bit Field/Programming Model	Value
Check the low-level info bit.	<a href="#">SLIMBUS_DCT_INFO_j</a> [3] LOLEVEL	=0x1
Clear the interrupt status bit of the data agent.	<a href="#">SLIMBUS_CMP_IRQSTATUS</a>	0x1
Read <a href="#">SLIMBUS_DCT_FIFO_SETUP2_j</a> [23:16] DMA_THRESHOLD segment words from FIFO.	<a href="#">SLIMBUS_DCT_DATA_j</a>	See <sup>(1)</sup>
Additionally, software can check if no more space is available to write	<a href="#">SLIMBUS_DCT_FIFO_STATUS_j</a> [0] FULL	=0x1
Clear the low-level info bit.	<a href="#">SLIMBUS_DCT_INFO_j</a> [3] LOLEVEL	0x1

<sup>(1)</sup> Segment word size varies between 1 and 8 slots (4 and 32 bits). Segments can be in packed or nonpacked mode.

This procedure enables DMA request generation to the sDMA or aDMA engine, which must be configured in advance. DMA request starts whenever the threshold condition is met. DMA requests stops after a certain number of nonempty read accesses to the FIFO are complete. This size typically corresponds to a DMA burst and in the [SLIMBUS\\_DCT\\_FIFO\\_SETUP1\\_j](#)[4:1] DMA\_REQ\_SIZE bit field.

**Table 23-703. Transmitting Data, DMA Enable**

Step	Register/Bit Field/Programming Model	Value
Set DMA request size (for presize DMA mode).	<a href="#">SLIMBUS_DCT_FIFO_SETUP1_j</a> [4:1] DMA_REQ_SIZE	0x-
Enable the data receive DMA requests. Write 0x1 for the required TX data agent.	<a href="#">SLIMBUS_CMP_DMAENABLE_SET</a>	0x1

### 23.9.5.1.7 Event Handling

Events must be serviced in the following way:

1. Clear the interrupt status bit (if interrupts are enabled).
2. Read the relative information register to determine the event.
3. Process the event as required. See [Section 23.9.4.11.1, Interrupt Requests](#).
4. When needed and allowed, clear the information register bit(s). For example, it is not necessary to clear the [SLIMBUS\\_SMR\\_INFO](#)[2] RECEIVED\_MESSAGE bit until the message is read, decoded, and executed, as it will allow the reception of other messages.

## 23.9.6 SLIMbus Register Manual

### 23.9.6.1 SLIMbus Register Overview

The registers described in this section are prefixed with one of the following:

- **CMP:** Component- (that is, module) level control and status.
- **SMT:** Shared Messages Transmit: All messages transmitted to the serial SLIMbus interface. This resource is shared by all devices within the component (all devices can transmit messages).
- **SMR:** Shared Messages Receive: All messages received from the serial SLIMbus interface. This resource is shared by all devices within the component (all devices can receive messages).
- **FL:** Frame Layer status and control. The frame layer is the hardware-implemented protocol layer located just above the physical layer, and shared by all devices of a component.
- **FR:** Framer device-specific status and control. The framer device is one of the component's devices (logical entities of the SLIMbus); exactly one framer device may optionally be implemented in each SLIMbus component. Note that the framer device is not always active (in which case the related registers aren't used either), and that some of the framer's control and status is shared with the (always-present, always-active) interface device.
- **DEV:** Device control and status. The same register structure is repeated as many times as there are devices supported by the component (that is, the module), including the (compulsory) interface device, the framer device (optional), the manager device (optional), and the generic devices (optional, one or several instances).
- **DCT:** Data Channel Transmit: The same register structure is repeated as many times as there are transmit data channels supported, that is, FIFOs and associated logic. Devices (typically generic devices) are associated to a data channel for the transmissions of data towards the SLIMbus serial interface.
- **DCR:** Data Channel Receive: The same register structure is repeated as many times as there are receive data channels supported, that is, FIFOs and associated logic. Devices (typically generic devices) are associated to a data channel for the reception of data from the SLIMbus serial interface.

### 23.9.6.2 SLIMbus Instance Summary

Table 23-704 shows the base address and address space for the SLIMbus module instances.

**Table 23-704. SLIMbus Instance Summary**

Module Name	Base Address L3 Interconnect	Base Address Cortex-A9 Private Access	Base Address DSP Private Access	Size
SLIMBUS1	0x4902 C000	0x4012 C000	0x2 C000	4 KB
SLIMBUS2	0x4807 6000	-	-	4 KB

**NOTE:** Private Access is an access which is not using the L3/L4 interconnects.

### 23.9.6.3 SLIMbus Registers

#### 23.9.6.3.1 SLIMBUS1 Register Summary

**Table 23-705. SLIMBUS1 Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address L3 Interconnect	Physical Address Cortex-A9 Private Access	Physical Address DSP Private Access
<a href="#">SLIMBUS_CMP_REVISION</a>	R	32	0x0000 0000	0x4902 C000	0x4012 C000	0x2 C000

**Table 23-709. SLIMBUS\_CMP\_HWINFO**

<b>Address Offset</b>	0x0000 0004		
<b>Physical Address</b>	0x4902 C004 0x4012 C004 0x2 C004 0x4807 6004	<b>Instance</b>	SLIMBUS1_L3 SLIMBUS1_CORTEX-A9 SLIMBUS1_DSP SLIMBUS2_L3
<b>Description</b>	Those read-only, hardcoded fields display the values of the eponymous hardware configuration depending on module instantiation - SLIMBUS1 or SLIMBUS2.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DEV		TDC		RDC		RRSZ				TRSZ				PSZ																	

Bits	Field Name	Description	Type	Reset
31:28	DEV	Device count: number of devices supported by the component, most notably through the automatic reception of the messages addressed to them. Sets the number of instances of the "DEV_XYZ" registers.	R	0x7
27:24	TDC	Transmit Data agent Count: Number of transmit hardware data agents (FIFO and associated logic) Sets the number of instances of the "DCT_XYZ" registers.	R	See <a href="#">Table 23-711</a>
23:20	RDC	Receive Data agent Count: Number of receive hardware data agents (FIFO and associated logic) Sets the number of instances of the "DCR_XYZ" registers.	R	See <a href="#">Table 23-711</a>
19:12	RRSZ	Size of receive FIFO RAM, in 32-bit words. RX message FIFO and all RX data FIFOs map to that shared RAM.	R	See <a href="#">Table 23-711</a>
11:4	TRSZ	Size of transmit FIFO RAM, in 32-bit words. TX message FIFO and all TX data FIFOs map to that shared RAM.	R	See <a href="#">Table 23-711</a>

Bits	Field Name	Description	Type	Reset
3:0	PSZ	Size of (both TX and RX) FIFO segment word pointers, in bits. Determines the maximum number of (variable-sized) segment words a data agent FIFO can contain. Sets the width of FIFO control and status fields: size, threshold, level.	R	0x8

<b>Description</b>	This register allows controlling various parameters of the interconnect interface		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																AUTOGATINGDISABLE	RESERVED				IDLEMODE	RESERVED	SOFTRESET								

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x000000
8	AUTOGATINGDISABLE	Control of the internal clock autogating for safety / debug only. No impact on module functionality, only on dynamic power. 0x0: Internal clocks are gated off when unused, power is optimized. 0x1: Internal clocks are free-running, maximum dynamic power.	RW	0
7:4	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
3:2	IDLEMODE	<p>Configuration of the local target state management mode. By definition, target can handle read/write transaction as long as it is out of IDLE state.</p> <p>0x0: Force-idle mode: local target's idle state follows (acknowledges) the system's idle requests unconditionally, that is, regardless of the IP module's internal requirements. Backup mode, for debug only.</p> <p>0x1: No-idle mode: local target never enters idle state. Backup mode, for debug only.</p> <p>0x3: Smart-idle wakeup-capable mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module may generate (IRQ- or DMA-request-related) wakeup events when in idle state. Mode is only relevant if the appropriate IP module "swakeup" output(s) is (are) implemented.</p> <p>0x2: Smart-idle mode: local target's idle state eventually follows (acknowledges) the system's idle requests, depending on the IP module's internal requirements. IP module shall not generate (IRQ- or DMA-request-related) wakeup events.</p>	RW	0x2
1	RESERVED		R	0
0	SOFTRESET	<p>Software reset. (Optional)</p> <p>Write 0x0: No action</p> <p>Write 0x1: Initiate software reset</p> <p>Read 0x1: Reset (software or other) ongoing</p> <p>Read 0x0: Reset done, no pending action</p>	RW	0

Bits	Field Name	Description	Type	Reset
31:9	RESERVED		R	0x0000000
8	VALIDATE_DCMAP	Validates the mapping of data channels on devices: to be used after modifying the DC*_MAP* fields (DI and PN).  Write 0x0: No action Write 0x1: Validates all DCT_MAP / DCR_MAP values	RW	0

Bits	Field Name	Description	Type	Reset
7	CLEAR_RECONFIGURATION	Clear all updates cumulated since the last reconfiguration, return reconfiguration fields to currently active value. Self-cleared immediately. Write 0x0: No action Write 0x1: Clear reconfiguration	RW	0
6	BUS_SHUTDOWN	Sets both the clock source or the clock receiver FSMs back to "Undefined" state at the next reconfiguration boundary. Executed (and bit self-cleared) on next reconfiguration (forced or not); also cleared by a "clear_reconfiguration". Write 0x0: Cancel pending request (not used in normal operation) if any, otherwise no action Write 0x1: Assert request for next reconfiguration Read 0x1: Request pending for next reconfiguration Read 0x0: No request pending for next reconfiguration	RW	0
5	KILL_FS	Force immediate Frame Synchronization loss (implying as well message and superframe sync) When in "Operational", "SeekingMessageSync" or "SeekingSuperFrameSync" states, component shall go to "SeekingFrameSync" and start reaquiring frame sync. No effect otherwise. For debug use. Write 0x0: No action Write 0x1: Force frame sync loss Read 0x0: Always reads 0 because of immediate action.	RW	0
4	KILL_SFS	Force SuperFrame Synchronization loss at next reconfiguration boundary (implying as well message sync loss). When in "Operational" or "SeekingMessageSync" states, component shall go to "SeekingSuperFrameSync" and start reaquiring superframe sync. No effect otherwise. Used by clock receiver component upon imcompletely received reconfiguration sequence. Write 0x0: No action Write 0x1: Schedule superframe sync loss Read 0x1: Superframe sync loss pending Read 0x0: No pending superframe sync loss	RW	0
3	KILL_MS	Force an immediate Message Synchronization loss. When in "Operational" state, component shall go to "SeekingMessageSync" and start reaquiring message sync. No effect otherwise. For debug use. Write 0x0: No action Write 0x1: Force message sync loss Read 0x0: Always reads 0 because of immediate action.	RW	0
2	FORCE_RECONFIGURE	Force a reconfiguration boundary at next superframe boundary, rather than wait for a RECONFIGURE_NOW() message. Write 0x0: Cancel pending request (not used in normal operation) if any, otherwise no action Write 0x1: Assert reconfiguration request for next superframe boundary Read 0x1: Reconfiguration request pending for next superframe boundary Read 0x0: No request pending	RW	0

Bits	Field Name	Description	Type	Reset
1	COMPONENT_RESET	<p>Component reset request control: Transitions clock receiver FSM to state "Reset" (from any other state). Immediate action.</p> <p>Set upon reception of the RESET_DEVICE() message by the interface device, which requires a component-level reset.</p> <p>Note that a component-level reset is also required in case of bus reset, but the transition to "Reset" state happens automatically in that case and this bit is not used.</p> <p>Write 0x1: Assert request for next reconfiguration</p>	RW	0
0	BOOT	<p>Boot the component when not in active framer mode (don't care when in active framer mode). Transitions clock receiver FSM from state "Undefined" to "Reset".</p> <p>0x0: No action</p> <p>0x1: Enable clock receiver boot sequence</p>	RW	0

If ACC_CNT &gt; 0, DMA request gets deasserted immediately.</p> <p>Write 0x1: Enable down-counter mode. ACC_CNT is typically set to the desired value in the same write access.</p> <p>Read 0x1: Down-counter mode is enabled: DMA request can only be active when ACC_CNT &gt; 0</p> <p>Read 0x0: Down-counter mode is disabled: DMA request follows FIFO level, and is active during no-transmission periods.</p>	RW	0
30:16	ACC_CNT	<p>"Packet mode" down-counter of segment words, decremented on DCR_DATA read accesses. In that mode, DMA request shall reassert when ACC_CNT = RD_LEVEL (that is, whole packet received).</p> <p>Write 0x0: Deasserts current DMA request by forcing the count to zero (not typical operation)</p> <p>Write 0x7F: Set largest packet size (in accesses) to transfer before DMA request deassertion. Any lower value is also valid to enter.</p> <p>Read 0x7F: Maximum number of accesses still to be transferred before DMA deassertion. Unless interrupted, counter shall go through all values down to zero.</p> <p>Read 0x0: No access left to transfer, DMA request currently inactive.</p>	RW	0x0000
15	IMPRECISE_EN	<p>Precise vs. Imprecise DMA requesting mode control. (A DMA request is a single assertion-deassertion cycle.)</p> <p>0x0: DMA request contains a defined number of accesses</p> <p>0x1: DMA request is not expected to trigger a fixed number of accesses</p>	RW	0
14:11	RESERVED		R	0x0
10:2	RD_LEVEL	<p>Number of segment words stored in FIFO, that can be read out.</p> <p>Read 0x100: FIFO is full of readable words (assuming maximum size)</p> <p>Read 0x0: FIFO contains no readable word</p>	R	0x000
1	HILEVEL	<p>Indicator of read level (RD_LEVEL: number of readable segment words) with respect to (read) threshold (DMA_THRESHOLD). Activates DMA read requests when high.</p> <p>Read 0x1: RD_LEVEL &gt; DMA_THRESHOLD</p> <p>Read 0x0: RD_LEVEL &lt;= DMA_THRESHOLD</p>	R	0
0	EMPTY	<p>FIFO empty indicator</p> <p>Read 0x1: FIFO contains no readable word (RD_LEVEL = 0)</p> <p>Read 0x0: FIFO contains at least one readable word (RD_LEVEL &gt; 0)</p>	R	1

## 23.10 MIPI-HSI

This section describes the MIPI high-speed synchronous serial interface (HSI).

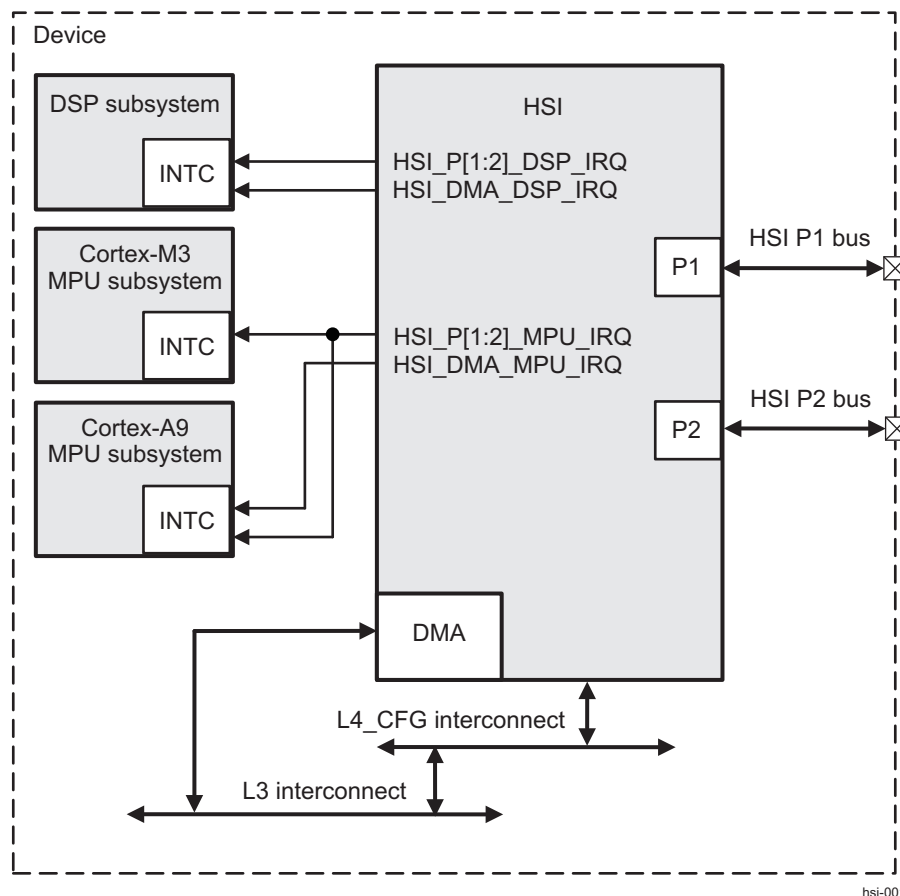

### 23.10.1 HSI Overview

The MIPI HSI module is a multichannel and full-duplex serial communications interface, composed of two transmitters (HST) in charge of the transmitted information and two receivers (HSR) in charge of the received information, sharing a 16-channel DMA.

The HSI peripheral is typically used to enable the device to exchange information with an external cellular modem.

Figure 23-217 is an overview of the HSI module.

**Figure 23-217. HSI Overview**

hsi-001

HSI supports the following features:

- Full duplex
- No static clock matching
- Interface speed up to 192 Mbps on transmitter and up to 225 Mbps on receiver
- Transmission speed and operation mode dynamically configurable
- Logical channels:
  - Up to 16 logical channels on receiver
  - Up to 16 logical channels on transmitter
- One 32-request DMA engine:
  - 16 transmit + 16 receive requests from HSI port

- 16 logical DMA channels
- Interrupt requests:
  - Three to each processor subsystem (two from HSI port, one from DMA)

### 23.10.2 HSI Environment

This section describes the HSI application fields from an environment point of view (external connections).

#### 23.10.2.1 HSI Signals

[Table 23-804](#) describes the HSI module I/O signals.

**Table 23-804. HSI I/O Signals**

Pin Name	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>
hsi1_cawake	I	HSI port 1 wake-up signal from an external serial transmitter	hi-Z
hsi1_cadata	I	HSI port 1 receiver data from an external transmitter	hi-Z
hsi1_caflag	I	HSI port 1 receiver flag from an external transmitter	hi-Z
hsi1_acready	O	HSI port 1 synchronization signal to an external transmitter	0
hsi1_acwake	O	HSI port 1 wake-up signal to an external serial receiver	0
hsi1_acdata	O	HSI port 1 transmission data (level transmission signaling) to an external receiver	1
hsi1_acflag	O	HSI port 1 transmission flag (bit transition signaling) to an external receiver	1
hsi1_caready	I	HSI port 1 synchronization signal from an external receiver	hi-Z
hsi2_cawake	I	HSI port 2 wake-up signal from an external serial transmitter	hi-Z
hsi2_cadata	I	HSI port 2 receiver data from an external transmitter	hi-Z
hsi2_caflag	I	HSI port 2 receiver flag from an external transmitter	hi-Z
hsi2_acready	O	HSI port 2 synchronization signal to an external transmitter	0
hsi2_acwake	O	HSI port 2 wake-up signal to an external serial receiver	0
hsi2_acdata	O	HSI port 2 transmission data (level transmission signaling) to an external receiver	1
hsi2_acflag	O	HSI port 2 transmission flag (bit transition signaling) to an external receiver	1
hsi2_caready	I	HSI port 2 synchronization signal from an external receiver	hi-Z

<sup>(1)</sup> I = input; O = output; I/O = Bidirectional

<sup>(2)</sup> hi-Z = High impedance

---

**NOTE:** The path from a module pin to device pad(s) is defined at the device I/O logic level. The I/O logic maps the module signals to the different pads of the device and is programmable in the Control Module registers. For more information on Control Module settings, refer to [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), and [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#), in [Chapter 18, Control Module](#).

---

#### 23.10.2.2 HSI Typical Application

[Figure 23-218](#) shows the HSI typical application.

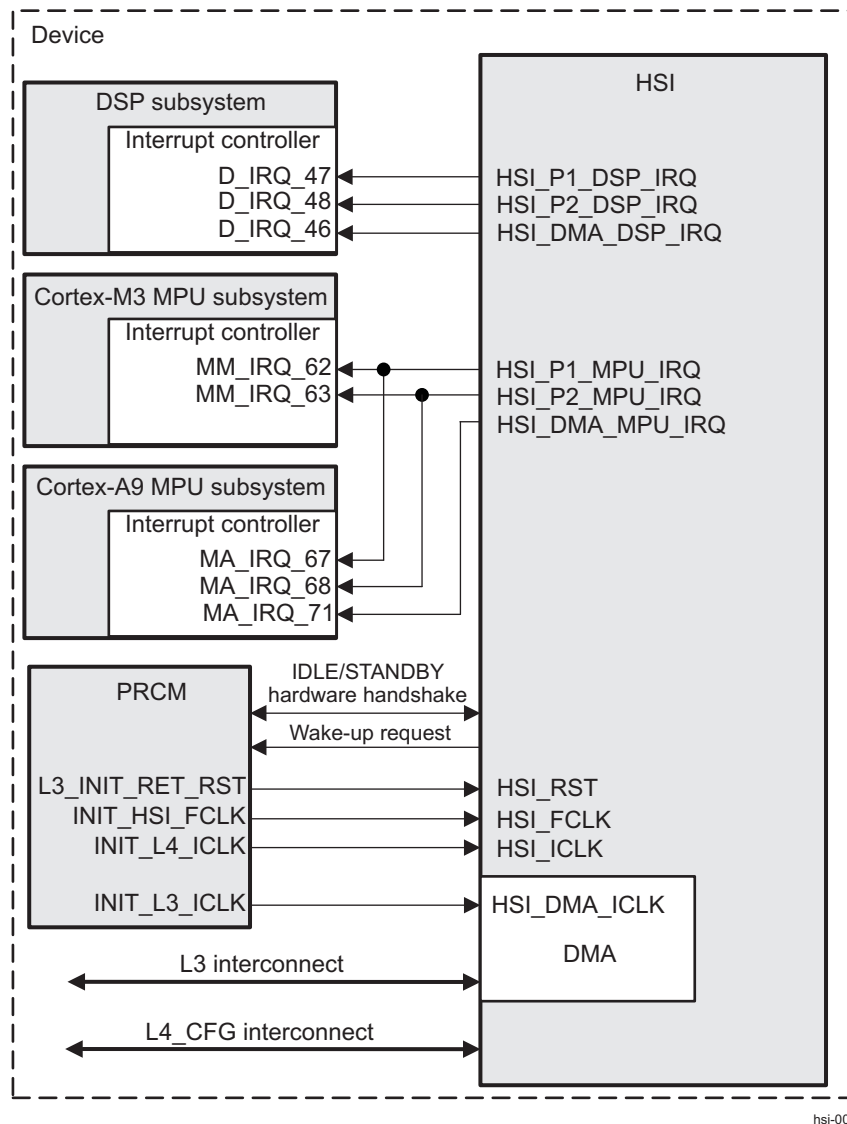

**Figure 23-218. HSI Typical Application**

### 23.10.3 HSI Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

[Figure 23-219](#) shows the HSI module integration.

Figure 23-219. HSI Integration

**NOTE:** For more information about the IDLE/STANDBY hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Interrupt lines HSI\_P1\_MPU\_IRQ and HSI\_P2\_MPU\_IRQ are shared between the Cortex-A9 MPU and Cortex-M3 MPU INTCs. It is strongly recommended to unmask each interrupt source in only one INTC at a time.

Table 23-805 through Table 23-807 summarize the integration of the module in the device.

Table 23-805. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
HSI	PD_L3_INIT	NA	L3 L4_CFG

**Table 23-806. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSI	HSI_FCLK	INIT_HSI_FCLK	PRCM	HSI module functional clock

	HSI_P2_MPU_IRQ <sup>(1)</sup>	MA_IRQ_68	Cortex-A9	HSI MPU request – Port 2
No DMA Requests				

<sup>(1)</sup> Interrupts shared between the Cortex-A9 MPU INTC and Cortex-M3 MPU INTC

**NOTE:** For a description of interrupt sources, see [Section 23.10.4.5, Interrupt Requests](#).

---

## 23.10.4 HSI Functional Description

**NOTE:** In the functional description section, the following common internal signal names are used for the corresponding external HSI signals (for simplification):

- WAKE: hsi1\_cawake, hsi1\_acwake, hsi2\_cawake, and hsi2\_acwake
  - DATA: hsi1\_cadata, hsi1\_acdata, hsi2\_cadata, and hsi2\_acdata
  - FLAG: hsi1\_caflag, hsi1\_acflag, hsi2\_caflag, and hsi2\_acflag
  - READY: hsi1\_acready, hsi1\_caready, hsi2\_acready, and hsi2\_caready
- 

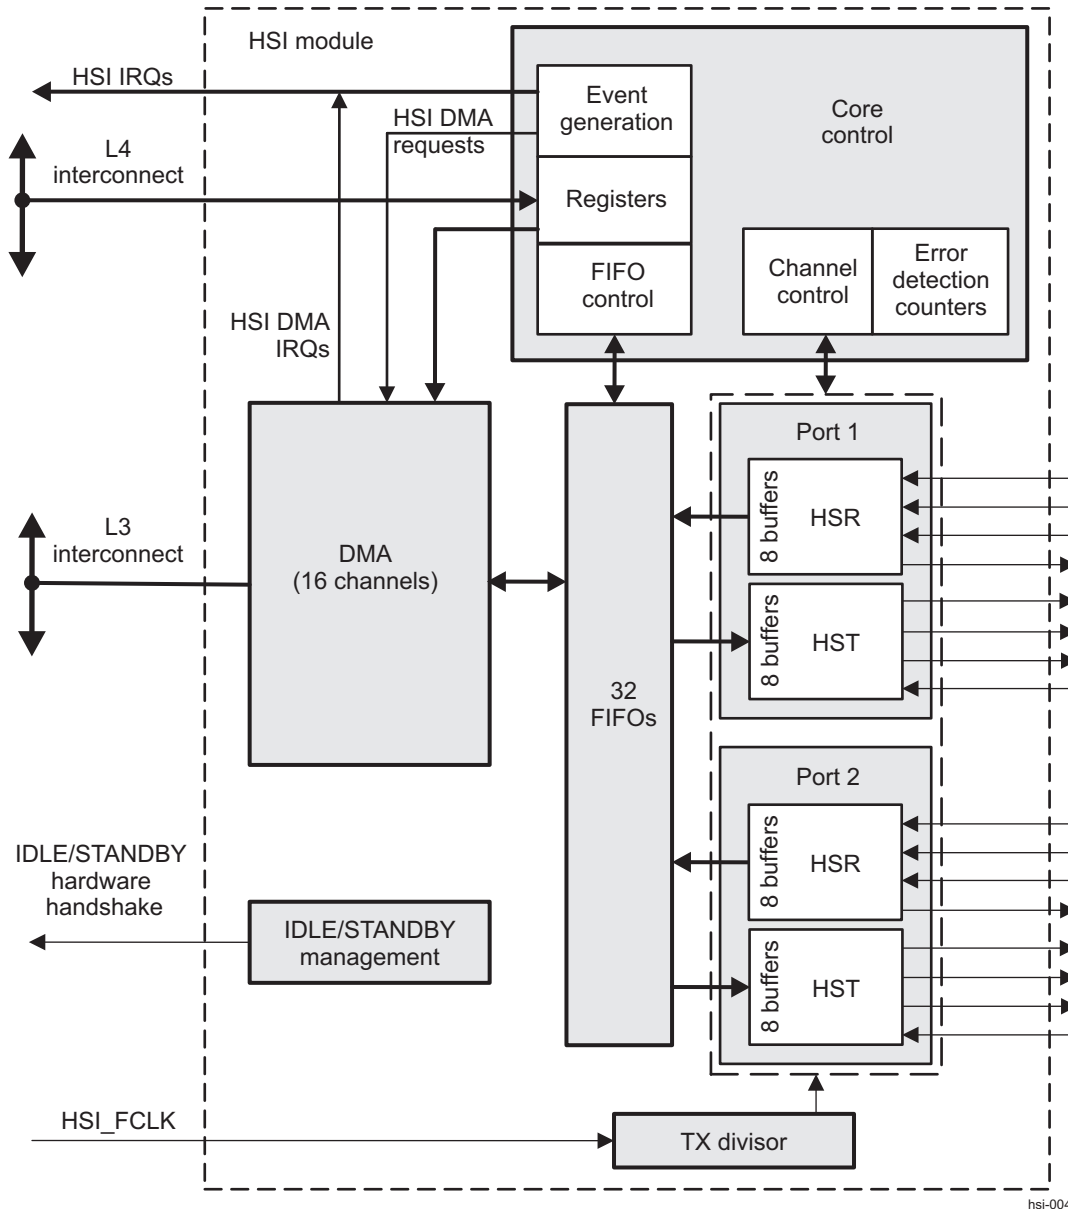

### 23.10.4.1 Block Diagram

The HSI controller is a subsystem built around two full-duplex multichannel synchronous serial interfaces. It contains a 16-bidirectional-logical-channel DMA in charge of handling data transfers between HSI modules and the L3 interconnect. Interrupt access to data is also available.

**NOTE:** Transmit data cannot be read back, and received data cannot be written in DMA and IRQ-based transfers.

---

[Figure 23-220](#) shows most HSI module features.

**Figure 23-220. HSI Controller Architecture Overview**

hsi-004

**NOTE:** A bypass path in the DMA allows a processor (MPU or DSP) to retrieve or provide data received or to be transmitted on an interrupt triggered access, when the DMA is not enabled.

### 23.10.4.2 Clock Configuration

The HSI module has four fully asynchronous clock domains:

- Interface clock domain
- Functional clock domain
- Receive clock domain on port 1
- Receive clock domain on port 2

### 23.10.4.2.1 Interface Clock Domain

The following clocks are part of the interface clock domain:

- HSI\_DMA\_ICLK runs the interface master port (L3). This clock is used for DMA master access to the L3 interconnect and also serves as the DMA functional clock.
- HSI\_ICLK runs the interface slave port (L4). This clock is used to configure the module and to transmit and receive data through register access in an interrupt-based manner.

### 23.10.4.2.2 Functional Clock Domain

The functional clock (HSI\_FCLK) runs the transmitter/receiver logic.

#### 23.10.4.2.2.1 Transmit Clock

The transmit clock is obtained from the functional clock and is used to generate transmitter DATA and FLAG lines, according to the standard. Namely, the DATA line must always reflect the transmitted bit value, whereas the FLAG line must provide a transition (0 to 1, or 1 to 0) when the current DATA value is the same as the previous one.

The transmit data rate is programmable through the [HST\\_DIVISOR\\_Pp\[7:0\]](#) TX\_RATE\_DIV\_VAL bit field.

$$\text{Transmit clock} = \text{HSI\_FCLK} / (\text{TX\_RATE\_DIV\_VAL} + 1).$$

#### 23.10.4.2.2.2 Receive Error Detection Counters Clocks

The functional clock is also used to obtain clocks for receive error counters, which are independently divided versions of the functional clock. Division is set by software through the [HSR\\_DIVISOR\\_Pp\[7:0\]](#) RX\_RATE\_DIV\_VAL bit field, which sets the bit rate clock for the frame time-out counter. This clock is further divided to generate an edge per frame to be sent to the frame burst counter.

### 23.10.4.2.3 Receive Clock Domain (Port 1 and Port 2)

The RX clock is retrieved from the DATA and FLAG signals available on the serial interface. A self-clocked source synchronous receiver implementation is done as follows: simple XOR of the DATA and FLAG signals recovers a signal displaying a transition on every bit time. From this signal, two clocks are generated with the appropriate phase, which can recover bit values, by sampling the DATA line, where the transmitted bit is always available.

### 23.10.4.3 Software Reset

The HSI module can be reset by software through the [HSI\\_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting this bit to 1 enables an active global software reset that is functionally equivalent to a hardware reset. The [HSI\\_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is set to 1. Software must ensure that the software reset completes before performing HSI operations.

The DMA engine can be independently reset by software through the [DMA\\_GRST\[0\]](#) SWRESET bit. Setting this bit to 1 resets the DMA registers and logic. This bit is automatically cleared when the DMA reset completes.

### 23.10.4.4 Power Management

[Table 23-808](#) describes power-management features available for the HSI module.

---

**NOTE:** For descriptions of IdleMode and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

---

**Table 23-808. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	<a href="#">HSI_SYSCONFIG</a> [0] AUTOIDLE <a href="#">DMA_GCR</a> [3] AUTOGATING	This bit allows a local power optimization inside the module by gating the HSI_ICLK clock upon the interface activity. This bit allows a local power optimization inside the module by gating the HSI_DMA_ICLK clock upon the interface activity.
Slave idle modes	<a href="#">HSI_SYSCONFIG</a> [4:3] SIDLEMODE	Force-idle, no-idle, smart-idle, and smart-idle wakeup-capable modes are available.
Master standby modes	<a href="#">HSI_SYSCONFIG</a> [13:12] MIDLEMODE	Force-standby, no-standby, smart-standby, and smart-standby wake-up modes are available.

#### 23.10.4.4.1 HSI Module Power-Management Modes

##### 23.10.4.4.1.1 Standby

When asserted, this signal informs the PRCM module that HSI is quiet and does not generate any traffic on the interconnect.

The HSI module supports four STANDBY handshake modes, selected through the [HSI\\_SYSCONFIG](#)[13:12] MIDLEMODE bit field:

- Force-standby (0x0): Selecting this mode asserts the standby signal unconditionally of the HSI activity. Software must ensure that HSI is disabled and does not generate any activity before activating this mode.
- No-standby (0x1): Standby signal is never asserted.
- Smart-standby (0x2): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion).
- Smart-standby wakeup (0x3): Standby signal is asserted when internal HSI DMA does not generate activity anymore (namely, upon DMA idle acknowledge signal assertion). It can also generate a wake-up request.

##### 23.10.4.4.1.2 Idle

The PRCM module asserts an IDLE request signal when it requires the HSI slave port to be idled. Any access to this port after the IDLE request signal has been asserted generates an error.

The HSI module supports four IDLE handshake modes, selected through the [HSI\\_SYSCONFIG](#)[4:3] SIDLEMODE bit field:

- Force-idle (0x0): An IDLE request is acknowledged unconditionally.
- No-idle (0x1): An IDLE request is never acknowledged.
- Smart-idle (0x2): Acknowledgment to an IDLE request is given based on the internal HSI module activity.
- Smart-idle wakeup (0x3): Acknowledgment to an IDLE request is given based on the internal HSI module activity. Additionally, when in this mode, the HSI module is allowed to generate a wake-up request.

##### 23.10.4.4.1.3 Auto-Idle

The HSI module provides an auto-idle option for the interface clock domain. Auto-idle mode is enabled by setting the [HSI\\_SYSCONFIG](#)[0] AUTOIDLE and/or [DMA\\_GCR](#)[3] AUTOGATING bits to 1. When this mode is enabled and there is no activity on the interconnect interface, the interface clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interface clock is restarted without any latency penalty.

### 23.10.4.4.1.4 DMA Engine Switch Off Mode

The DMA interface clock (HSI\_DMA\_ICLK) can be switched off by setting the [DMA\\_GCR\[0\] SWITCH\\_OFF](#) bit to 1. DMA clock activity is then cut off. Software must ensure that ongoing transitions are complete before cutting off clocks. Once the DMA is switched off, access to reset this bit is possible only through the configuration port.

### 23.10.4.5 Interrupt Requests

[Table 23-809](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 23-809. Events**

Event Flag	Event Mask	Map to	Description
<a href="#">HSI_Pp_M_IRQrU_STATUS</a> [26] HSR_WAKE	<a href="#">HSI_Pp_M_IRQrU_ENABLE</a> [26] HSR_WAKE	HSI_P1_MPU_IRQ HSI_P2_MPU_IRQ	Wake detected on any channel 8–15.

### 23.10.4.5.1 Interrupts

By default, there are four interrupt output lines per HSI port (Mpuirq\_0, Mpuirq\_1, Dspirq\_0, Dspirq\_1), and two in the case of the DMA interrupt (MPU, DSP). The following registers are related to these interrupt outputs as follows:

- Status registers:
  - [HSI\\_Pp\\_M\\_IRQrU\\_STATUS](#) / [HSI\\_Pp\\_M\\_IRQr\\_STATUS](#) for Mpuirq\_r (where r = 0 or 1)
  - [HSI\\_Pp\\_D\\_IRQrU\\_STATUS/HSI\\_Pp\\_D\\_IRQr\\_STATUS](#) for Dspirq\_r (where r = 0 or 1)
  - [HSI\\_DMA\\_M\\_IRQSTATUS](#) for DMA interrupt to MPU
  - [HSI\\_DMA\\_D\\_IRQSTATUS](#) for DMA interrupt to DSP
- Enable registers:
  - [HSI\\_Pp\\_M\\_IRQrU\\_ENABLE](#) / [HSI\\_Pp\\_M\\_IRQr\\_ENABLE](#) for Mpuirq\_r (where r = 0 or 1)
  - [HSI\\_Pp\\_D\\_IRQrU\\_ENABLE/HSI\\_Pp\\_D\\_IRQr\\_ENABLE](#) for Dspirq\_r (where r = 0 or 1)
  - [HSI\\_DMA\\_M\\_IRQENABLE](#) for DMA interrupt to MPU
  - [HSI\\_DMA\\_D\\_IRQENABLE](#) for DMA interrupt to DSP

However, Mpuirq\_0 and Mpuirq\_1 are further combined (logical OR) into one common interrupt output per port (HSI\_P1\_MPU\_IRQ for port 1, and HSI\_P2\_MPU\_IRQ for port 2). The same goes for Dspirq\_0 and Dspirq\_1 (HSI\_P1\_DSP\_IRQ for port 1, and HSI\_P2\_DSP\_IRQ for port 2).

This means that it is enough to enable one of the FIFO/WAKE/BREAK/ERROR interrupt events per port (for example, in [HSI\\_Pp\\_M\\_IRQ0\(U\)\\_ENABLE](#)) to raise the corresponding interrupt request. Enabling both [HSI\\_Pp\\_M\\_IRQ0\(U\)\\_ENABLE](#) and [HSI\\_Pp\\_M\\_IRQ1\(U\)\\_ENABLE](#) would only mean extra checks and clears (in the corresponding IRQ status register). The same is true for the DSP-related IRQ enable/status registers.

The HSI module outputs six interrupt signals (for more information, see [Section 23.10.3, MIPI HSI Integration](#)). All the interrupts are active-high level-sensitive. Each interrupt line is activated by a set of individual sources. All interrupt sources can individually be enabled and disabled.

For each interrupt, 2 status bits and 2 mask bits are provided, allowing independent masking for the different processors (that is, 1 status bit and 1 mask bit for the MPU [Cortex-A9 or Cortex-M3] interrupts, and 1 status bit and 1 mask bit for the DSP interrupts).

Interrupts in the HSI module are intended to:

- Signal any error condition in reception
- Support the WAKE condition detection
- Support the BREAK condition detection
- Warn of DMA transfer status or problems

- Signal to processors when to read received data and to write data to transmit

Because DMA has only 16 channels, 16 RX FIFO and 16 TX FIFO are managed by a mix of DMA-driven and interrupt-driven read/write policies.

#### **23.10.4.5.1.1 HSI Interrupt Generation**

Five types of interrupt events can be generated by each HSI port:

- Transmit FIFO not full: Occurs when TX FIFO is not full, so data can be written for transmission
- Received data available: Occurs when one data frame has been received and is available on the RX FIFO for reading
- Overrun: Occurs when data overrun is detected on HSI port *p* channel *i*
- Error: Any error defined by the MIPI HSI protocol activates this source of interrupt if this source is enabled.
- Break condition detected: Occurs upon reception of a continuous string of 0s that exceed those possible in any FRAME mode frame (data + header). Because FRAME mode always put a 1 before any frame, the maximum number of 0s occurring during normal transmission is clearly 32 plus the base 2 logarithm of channels used. Hardware works out this number based on register information on channels and receive mode, sets the [HSR\\_BREAK\\_Pp\[0\]](#) BREAK\_VAL bit to 1, and issues an interrupt if this source is enabled.

All the events are cleared by software, upon setting the corresponding register bit to 1. Setting the bit to 0 has no effect.

#### **23.10.4.5.1.2 DMA Interrupt Generation**

Three types of interrupt events can be generated by each DMA channel:

- End of Block: Enabled through the [DMA\\_CSR\\_CCIR\\_i\[5\]](#) BLOCK\_IE bit, it occurs when the last element of the transfer has been written into destination. The [DMA\\_CEN\\_i\[15:0\]](#) SIZE bit field defines the number of elements in a block.
- Half Block: Enabled through the [DMA\\_CSR\\_CCIR\\_i\[2\]](#) HALF\_IE bit, it occurs when a half of the elements have been written into destination.
- Time-out error: Enabled through the [DMA\\_CSR\\_CCIR\\_i\[0\]](#) TOU\_IE bit, it occurs when destination slave answers by an error code.

All interrupt events are generated on the same logical channel dedicated interrupt line. When an interrupt is issued by a logical channel, its [DMA\\_CSR\\_CCIR\\_i](#) status register is set to record the interrupt cause, if the interrupt event bit is enabled in the relevant [DMA\\_CSR\\_CCIR\\_i](#) register. The processor interrupt service routine can read this channel status register to identify the sources of the interrupt. The status bits are automatically cleared after they are read by the processor, unless it is an emulation read.

There are two classes of DMA interrupt events:

- Error events: Errors during the transfer
- Status events: DMA transfer status, such as end of block or half-block

The DMA manages the two classes differently.

For an enabled error event, the following sequence occurs:

1. The appropriate bit in the [DMA\\_CSR\\_CCIR\\_i](#) register is set.
2. An interrupt is generated.
3. The ports are released.
4. The currently active logical channel is disabled and must be reprogrammed.
5. Other channels are not affected, and a new channel can get over, according to programmed priorities.

For an enabled status event, the following sequence occurs:

1. The appropriate bit in the [DMA\\_CSR\\_CCIR\\_i](#) register is set.
2. An interrupt is generated.
3. A new interrupt cannot be generated until the status register is read and thereby cleared.

All the events are cleared by software, upon setting the corresponding interrupt status register ([HSI\\_DMA\\_M\\_IRQSTATUS](#) or [HSI\\_DMA\\_D\\_IRQSTATUS](#)) to 1. Setting the interrupt status register to 0 has no effect.

### 23.10.4.6 DMA Module

#### 23.10.4.6.1 DMA Overview

The DMA module transfers data between the HSI interfaces and the device on-chip memories. The DMA module supports 16 logical channels and is a dual-port initiator (peripheral port/memory port) with one slave port for configuration. The memory port provides an interface to the memory space and the peripheral port provides an interface to the HSI interfaces. In the HSI controller, the L4\_CFG port accesses can be routed directly to the HSI interfaces. This is done by setting the DMA in bypass mode to route the DMA slave port to the DMA peripheral port.

DMA features:

- One target port, for configuration
- 16 logical channels:  $n$  for transmission and  $16-n$  for reception
- One initiator port, for transfer to/from memory
- One port to/from LCH memory (this memory holds some registers)
- 32-bit data handling only
- Constant addressing mode on peripheral port/FIFO
- Post-increment addressing mode with burst support on memory port
- Software enabling
- Hardware activation of data transfer on peripheral port
- Logical channels interleaving with only few-cycles-latency
- Fixed allocation of memory and peripheral port to a logical channel
- LCH first-come-first-served + fixed priority arbitration
- Low-power operation (hardware control for clock domains activity)
- Software reset

#### 23.10.4.6.2 DMA Memories

DMA channel register memory is managed by the DMA. Only the DMA interfaces this memory. A processor must program the DMA registers included in this memory.

The DMA has access to 16 dual-port FIFO 8 × 32 bits for reception and 16 dual-port FIFO 8 × 32 bits for transmission. They are provided in the form of two separate memories.

#### 23.10.4.6.3 DMA Basic Operation Outline

DMA write and read operations are helped by tags, to manage possibly disorderly answers. Posted or nonposted operations are possible. In any case, the interconnect always manages them as nonposted. This is consistent with DMA operations that need to know (for example, if main memory write was successful). If not, the error response from L3 interconnect slave produces a DMA error and the corresponding interrupt. DMA addressing of FIFO memories is always on a constant address, corresponding to 1 of the 16 [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) (or [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#)) registers.

These registers are associated with the 16 FIFOs, and the naming reflects only the reset value of the association FIFO, HSI logical channel. Therefore, at reset, the FIFO addressed on the [HSR\\_BUFFER\\_P2\\_CHN\\_4](#) register is associated with the fourth logical channel of the second port. Nevertheless, software can change this mapping and associate the same FIFO (for example, to the seventh channel of the first port). This mapping is performed by software through the [HST\\_MAPPINGf\[4:1\]](#) CH\_NUMBER or [HSR\\_MAPPINGf\[4:1\]](#) CH\_NUMBER bit fields.

#### 23.10.4.6.4 DMA Configuration

Before performing a DMA transfer, the following DMA registers must be configured:

- [DMA\\_CCR\\_CSDP\\_i](#): Sets source and destination parameters and channel control
  - [DMA\\_CCR\\_CSDP\\_i\[15:14\] DST\\_BURST\\_EN](#): Destination burst enable (0x0 and 0x1: single access; 0x2: burst 4 × 32 bits; 0x3: burst 8 × 32 bits)
  - [DMA\\_CCR\\_CSDP\\_i\[12:9\] DST](#): Transfer destination (0x8: transfer to memory port; 0x9: transfer to peripheral port)
  - [DMA\\_CCR\\_CSDP\\_i\[8:7\] SRC\\_BURST\\_EN](#): Source burst enable (0x0 and 0x1: single access; 0x2: burst 4 × 32 bits; 0x3: burst 8 × 32 bits)
  - [DMA\\_CCR\\_CSDP\\_i\[5:2\] SRC](#): Transfer source (0x8: transfer from memory port; 0x9: transfer from peripheral port)
  - [DMA\\_CCR\\_CSDP\\_i\[31:30\] DST\\_ADD\\_MODE](#): Destination addressing mode (0x0: constant address mode; 0x1: post-incremented address mode)
  - [DMA\\_CCR\\_CSDP\\_i\[29:28\] SRC\\_ADD\\_MODE](#): Source addressing mode (0x0: constant address mode; 0x1: post-incremented address mode)
- [DMA\\_CSR\\_CCIR\\_i](#): Enables DMA sources of interrupt events
- [DMA\\_CSSA\\_i\[31:0\] ADDR](#): Stores 32 bits of the source address
- [DMA\\_CDSA\\_i\[31:0\] ADDR](#): Stores 32 bits of the destination address
- [DMA\\_CEN\\_i\[31:0\] SIZE](#): Defines the number of elements in a block. The maximum number of elements is 65535.

To start a DMA transfer, the DMA channel to be used must be enabled by setting the [DMA\\_CCR\\_CSDP\\_i\[23\] ENABLE](#) bit to 1. Once the DMA transfer is finished, the [DMA\\_CCR\\_CSDP\\_i\[23\] ENABLE](#) bit is automatically reset by hardware.

The [DMA\\_CDAC\\_CSAC\\_i\[15:0\] ADDRESS\\_CSAC](#) (or [DMA\\_CDAC\\_CSAC\\_i\[31:15\] ADDRESS\\_CDAC](#)) bit field can be used to monitor the progress of a DMA transfer on the channel source (or destination). It is a snapshot of the source (or destination) address generated by the channel counter. It is incremented on each access made on channels.

#### 23.10.4.7 HSR Module

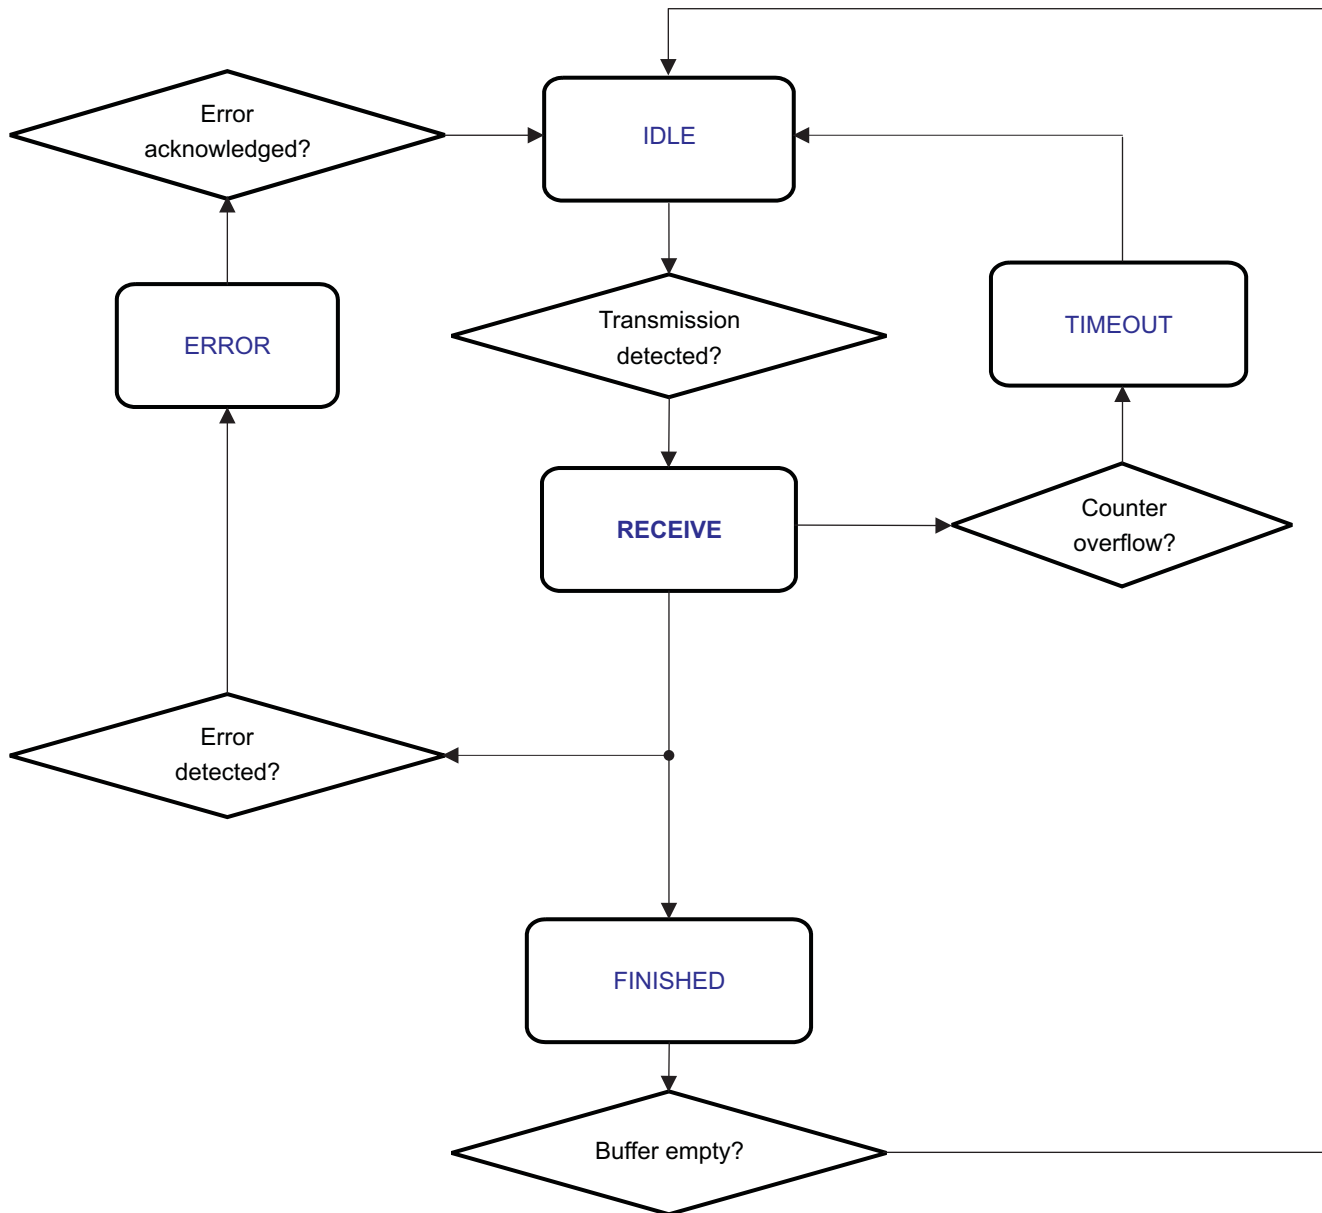

The HSR module is the receiver part of the HSI module. It features 16 channels.

##### 23.10.4.7.1 Receive Data

The value on the DATA line is always the transmitted bit, when sampled by the clock recovered. The double level of buffering allows the data to be safely transferred to the FIFO, while a new frame is stored. Data headers do not belong in FIFO and must be decoded to load data on the correct FIFO (there is one logical FIFO per logical channel).

[Figure 23-221](#) shows the receive state-machine implemented in the HSI module.

Figure 23-221. Receive FSM

hsi-007

### 23.10.4.7.2 Transmission Detection

Reception starts upon two alternate conditions:

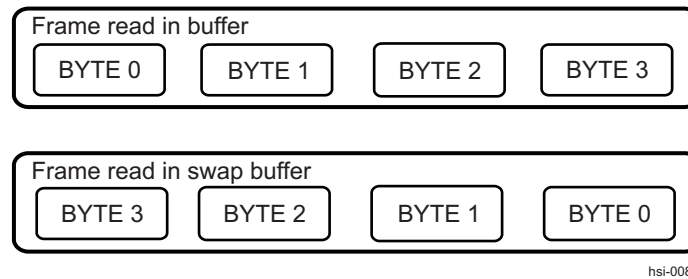

- The remote transmitter raises the WAKE line (in this case, it does not actually transmit until the local receiver raises the READY line).
- An activity (in the form of transitions) appears on the FLAG/DATA lines, in case the remote transmitter does not implement the WAKE signal. The receiver must then save and store the received data, at least one frame long, before preventing further transmission by setting READY to 0.

### 23.10.4.7.3 Receive Buffers

For each logical channel, the [HSR\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) DATA bit field holds one frame. The appropriate bit in the [HSR\\_BUFSTATE\\_Pp](#) register is set to 1 by hardware when the corresponding [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register holds one frame. Reading the [HSR\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) DATA bit field automatically resets the appropriate bit in [HSR\\_BUFSTATE\\_Pp](#). This lets the receiver put another data frame in [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#), setting again [HSR\\_BUFSTATE\\_Pp](#).

Some applications need reversed byte ordering of frames. This is supported by the [HSR\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register (see [Figure 23-222](#)). By reading this register instead of the corresponding [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register on the same channel, byte ordering of the 4 bytes in a frame is reversed.

**Figure 23-222. HSR\_SWAPBUFFER\_Pp\_CHN\_i Register**

hsi-008

Reading the MSB of the [HSR\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register sets the corresponding bit of [HSR\\_BUFSTATE\\_Pp](#) to empty.

---

**NOTE:** Read access to the register with 0x3 and 0xF byte-enable removes the receive FIFO-related item. If only 16-bit accesses are used, the upper 2 bytes must be read first (byte-enable 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

---

### 23.10.4.7.4 Receive Operations

Logically, the receiver amounts to the receiver shift register, double-buffering and the FSM. The current state of the FSM can be observed and controlled through the [HSR\\_RXSTATE\\_Pp\[2:0\]](#) RXSTATEVAL bit field. For the receive FSM, a functional description is shown in [Figure 23-221](#).

The receiver FSM is in IDLE state when no transmission is detected, or the [HSR\\_MODE\\_Pp\[1:0\]](#) MODE\_VAL bit field = FRAME and no synchronization bit is detected. Otherwise, it stores the first received bit and transitions to RECEIVING state, where it stops until a full frame is received.

Depending on the selected flow control, the READY line may have to go to 0 after the first bit is received.

Upon receiving a full frame, the FSM transitions to FINISHED state. Otherwise, the FSM transitions to TIMEOUT state as soon as a time-out value (if enabled and programmed in the [HSR\\_COUNTERS\\_Pp\[19:0\]](#) FT bit field) is reached. Then it moves to IDLE state.

After entering RECEIVED state, the FSM stays there until the received frame is correctly stored and there is room for another frame. At this point, READY is raised and the FSM goes to IDLE state. In pipelined flow, flow control by READY is not operating at each byte, and in real time flow it is never operating. In both cases, the FSM transitions immediately to IDLE, to receive more data. Illegal transitions or flags raised by error counters (see [Section 23.10.4.11, Error Reporting](#)), move the FSM to ERROR state, and then to HALT, to wait until the error is acknowledged by software, warned by an interrupt. Except for pipelined control flow, the READY output is always 1 in IDLE state and 0 anywhere else. In pipelined mode, the READY signal stays to 1, and is cleared by a condition on buffer full. The FSM state can be controlled by software by writing in the [HSR\\_RXSTATE\\_Pp\[2:0\]](#) RXSTATEVAL bit field. This can be useful to recover from an error condition.

### 23.10.4.7.5 Receive Exceptions

#### 23.10.4.7.5.1 Break

Remote transmitter can force synchronization by a long enough string of 0s (equal to the number of header + data bits in the frame + 1). In frame mode, this sets the [HSR\\_BREAK\\_Pp\[0\]](#) BREAK\_VAL bit to 1, which in turn sends an interrupt.

#### 23.10.4.7.5.2 Overrun

An overrun condition is possible during real-time flow, if received data occur when the FSM is in FINISHED state. Whenever this happens, the [HSR\\_OVERRUN\\_Pp\[15:0\]](#) OVERRUN\_VAL bit field is set for the corresponding logical channel, which in turn generates an interrupt.

An overrun exception is a legacy condition required in previous SSI hardware, where reception without the READY signal had to be supported. In HSI the READY signal always exists, but it cannot be used during real-time flow and the last 8 bits of a frame during pipelined flow. During real-time data flow, overrun can occur at any time. The main goal of using real-time flow is flushing FIFOs after an error. In that case, an overrun interrupt does not seem worth to be raised. Data does not have to be discarded. The real-time data are discarded if the receiver cannot follow the transmission rate, otherwise, the real-time data is kept in FIFO.

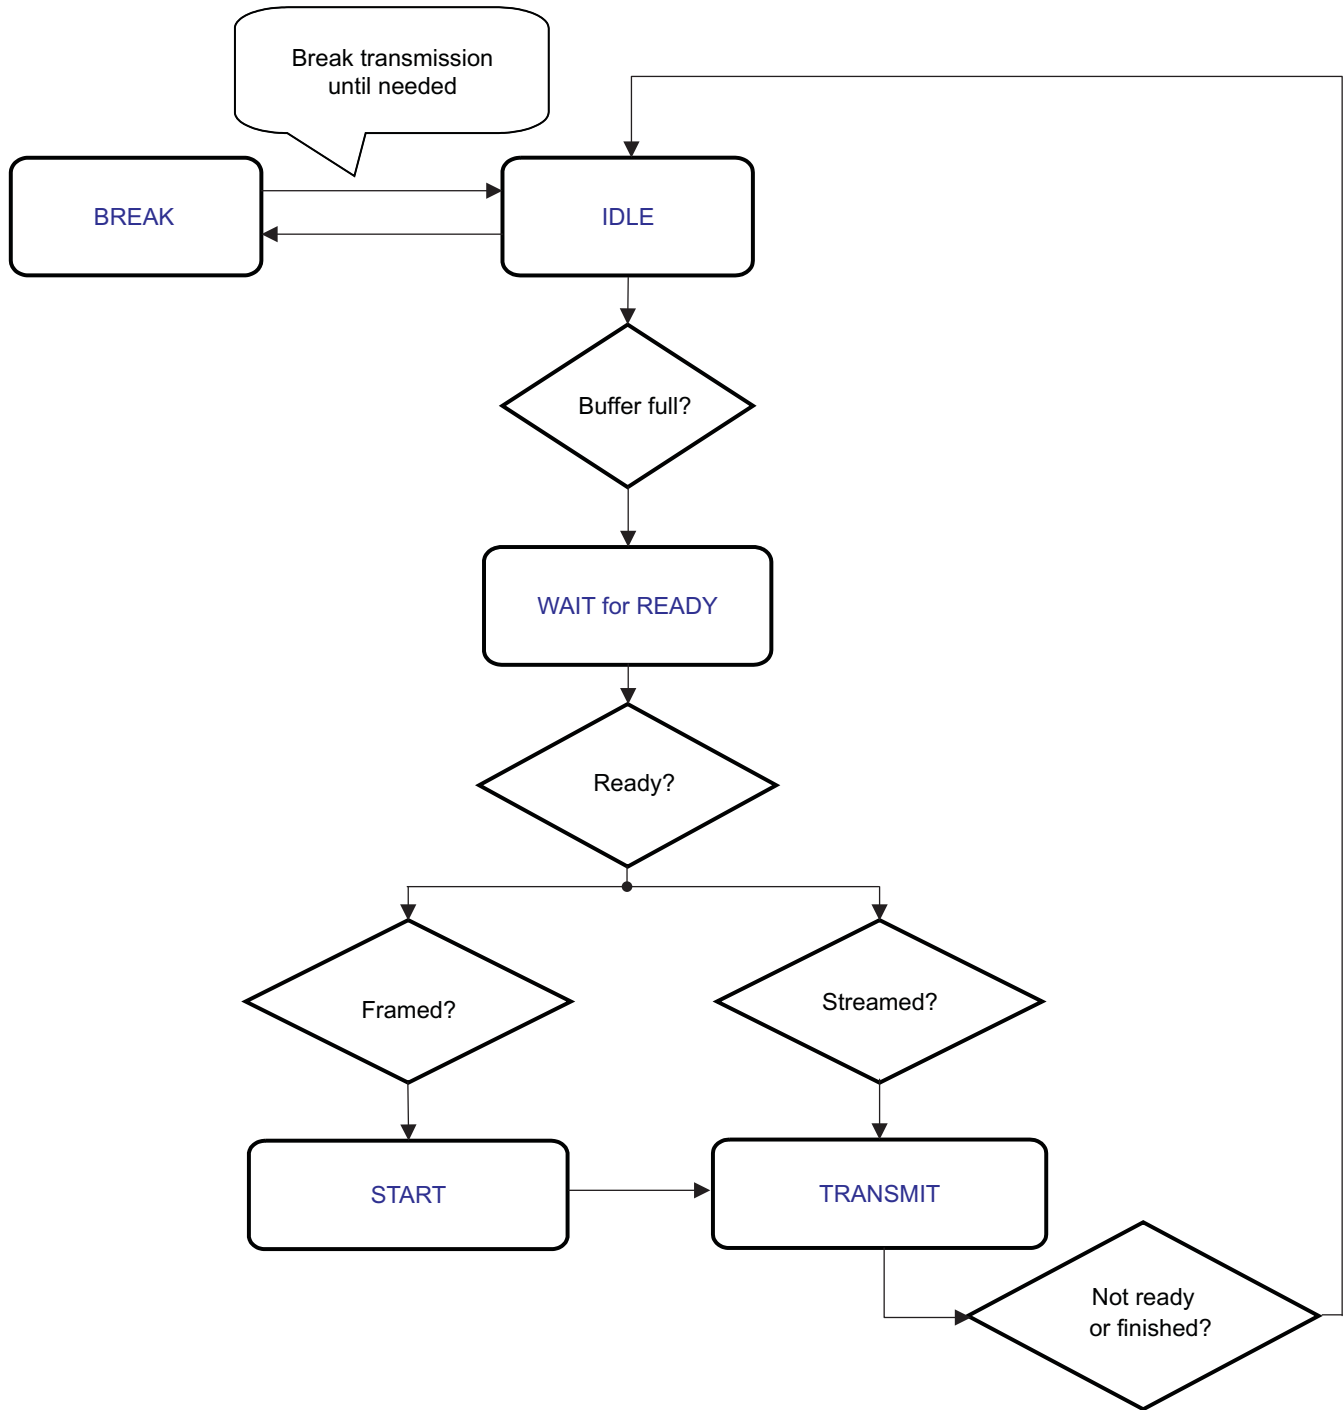

#### 23.10.4.7.5.3 Errors

Several sources of errors are possible. In any of them, the receiver FSM stays in ERROR state until the error interrupt is acknowledged by writing the [HSR\\_ERRORACK\\_Pp](#) registers. Sources of errors include receive FRAME TIMEOUT, other receive errors flagged by error counters, and any other abnormal condition, as explained in [Section 23.10.4.11](#), *Error Reporting*.

**23.10.4.8 HST Block**

The HST block is the transmitter part of the HSI module. It features 16 channels. Figure 23-223 shows the receive state-machine implemented in the HSI module.

**Figure 23-223. Transmit FSM**

hsi-009

**23.10.4.8.1 Configuration**

Configuration of the component is expressed in terms of operation mode, number of logical channels, bit rate divisor, and arbitration mode.

### 23.10.4.8.1.1 Mode Register

The `HST_MODE_Pp` register cannot be changed without stopping the link.

There is one `HST_MODE_Pp[3:2]` `FLOW_VAL` bit field for each active transmit channel and another `HSR_MODE_Pp[3:2]` `FLOW_VAL` bit field for each active receive channel. The local transmitter (communicating with the remote receiver) uses the `HST_MODE_Pp[3:2]` `FLOW_VAL` bit field for interpretation of the received `READY` line, for example to signal errors.

The `HST_MODE_Pp` register has the following bit fields:

- `WAKE_CTRL` selects between software (when 0x0) or automatic (when 0x1) control for the `WAKE` line. The default is software control.
- `MODE_VAL` defines the following operation modes:
  - Sleep: Specifies whether internal clocks must run and port be operating
  - Stream: Receiver does not use start-bits.
  - Frame: Allows break transmission/reception defined as a longer-than-frame 0 sequence
- `FLOW_VAL` defines the following data flows:
  - Synchronized flow: The `READY` signal from the receiver drops after every first frame bit, rising when data are stored, and transmission of a new frame is possible.
  - Pipelined flow: The receiver cannot drop the `READY` line at some times.
  - Real-time flow: The receiver drops the `READY` line at the first received bit and raises it at the last one.

---

**NOTE:** `READY` is activated when the module is going into `ACTIVE` state (stream or frame mode). Receive mode must be selected at the end of the configuration of the module, because it activates the transfer from the remote side. This prevents the device from receiving incorrect data, losing data, and falsely starting communication.

---

### 23.10.4.8.1.2 Other Registers

- The `HST_FRAMESIZE_Pp` register is kept to offer legacy compatibility. It is a read-only register, returning 0x1F.
- The `HST_DIVISOR_Pp[7:0]` `RX_RATE_DIV_VAL` bit field sets the transmission bit rate, with 1 transmitted bit per clock cycle. Bit rate can be changed by software at any time.
- The `HST_CHANNELS_Pp[4:0]` `CHAN_NUM_VAL` bit field sets the number of logical channels. It must be a power of 2. The default value is 0x1. This corresponds to only one logical channel, always the same, and in that case, a header is not transmitted; It cannot be changed without stopping the link.
- `HST_MAPPINGf` contains important settings for each FIFO (one register per FIFO):
  - `HST_MAPPINGf[0]` `ENABLE` bit: FIFO is enabled or not.
  - `HST_MAPPINGf[4:1]` `CH_NUMBER` and `HSR_MAPPINGf[7]` `PORT_NUMBER` bit fields (channel number and port number): FIFO is assigned to an HSI logical channel on a physical port.
  - `HST_MAPPINGf[13:10]` `THRESHOLD` bit field is the number of empty TX FIFO locations that will activate interrupt automatically.
- The `HST_ARBMODE_Pp[0]` `ARB_VAL` bit allows choosing of the arbitration policy for time allocation to logical channels, when several channels have to transmit. Round-robin algorithm implements a circular scan: the same channel cannot transmit twice if another channel is ready to transmit. Scan proceeds in the same, unspecified direction (design choice). Fixed priority algorithm grants maximum priority to logical channel 0, minimum priority to channel 15. The right to transmit is assigned to the higher priority channel ready to transmit, independently of previous transmissions.

The choice between algorithms must consider that round-robin sets a maximum wait time for each channel, but it may require a long time to transmit long sequences of frames, on any channel. On the other hand, fixed priority allows limiting of transmission time for high priority channels, while low priority channel may wait for a long time.

It is important to understand that this register sets the allocation of one port resource (transmission lines) from 2 to 16 vying transmit FIFOs. Allocation of the 16 transmit FIFOs to 32 logical channels is

done by the [HST\\_MAPPINGf](#) register. For this second kind of allocation, no arbitration makes sense, because software is in charge to ensure against more than 16 logical channels transmitting at the same time.

### 23.10.4.8.2 Mapping

[Figure 23-224](#) shows an example of programming the [HST\\_MAPPINGf](#) register. No limitation is set on the choice of channel/FIFO/port association.

Each port has its [HST\\_ARBMODE\\_Pp](#) register so that it is also possible to program alternate algorithms on ports.

While the [HST\\_MAPPINGf](#) register cares only about FIFO, the [HST\\_ARBMODE\\_Pp](#) register is associated to a port and each port has its own one, which only selects a winner between ready-to-transmit channels of this port. For example, suppose that in [Figure 23-224](#) only the three represented channels need to transmit; then a yellow (Port 1) arbiter chooses between channel 11 and channel 2, while the cyan (Port 2) arbiter has no decision to take and lets channel 3 transmit.

**Figure 23-224. MAPPING Register**

### 23.10.4.8.3 Transmission Buffer

The transmission buffer holds a frame to be transmitted for each channel. The [HST\\_BUFSTATE\\_Pp\[7:0\]](#) `BUFSTATE_VAL` bit field indicates whether the [HST\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) `DATA` bit field holds significant data, and it is not cleared until transmit FSM is in IDLE state and arbitration indicates the channel is the next in line to transmit. The [HST\\_BUFSTATE\\_Pp](#) register is automatically written by hardware.

---

**NOTE:** Write access to the register with 0x3 and 0xF byte-enable loads its value into the transmit FIFO. If only 16-bit accesses are used, the upper 2 bytes must be written first (byte-enable 0xC). Between two consecutive 16-bit FIFO-related accesses there cannot be any other FIFO-related OCP access.

---

Some applications need reversed byte ordering of frames. This is supported by the [HST\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register. By reading this register instead of the corresponding [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register on the same channel, byte ordering of the 4 bytes in a frame is reversed (see [Section 23.10.4.7.3, Receive Buffers](#)).

### 23.10.4.8.4 Break Pattern Transmission

Break pattern transmission is an alternative to normal transmission mode, and is used when trying to recover lost synchronization. It is started by software by setting the [HST\\_BREAK\\_Pp\[0\]](#) `BREAK_VAL` bit. As soon as transmit FSM is in IDLE state (ready to accept another frame for transmission), a nonzero value on the [HST\\_BREAK\\_Pp\[0\]](#) `BREAK_VAL` bit starts the BREAK sequence, and automatically clears the [HST\\_BREAK\\_Pp\[0\]](#) `BREAK_VAL` bit. A sequence of 0, longer than a frame, is transmitted.

### 23.10.4.8.5 Transmission Operations

The transmitter adds up to the transmit shift register, loaded from the transmission buffer, and the transmit FSM current state of the FSM can be observed and controlled through the [HST\\_TXSTATE\\_Pp\[2:0\]](#) TXSTATEVAL bit field. A functional description of the transmit FSM is shown in [Figure 23-223](#).

After reset, the transmitter is in IDLE state. It starts transmission when there is data in one of the transmission [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) registers, depending on the value of [HST\\_BUFSTATE\\_Pp\[7:0\]](#) BUFSTATE\_VAL bit field, or when the value of BREAK is not 0.

When transmitting a data frame (not a BREAK sequence), the frame to be transmitted is clocked from the [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register to the transmission shift register, and the FSM enters WAIT state until it receives READY = 1. At this point, it starts driving the DATA and FLAG lines with a preliminary start-bit at 1, if in STREAM mode, or with the frame, which amounts to header and payload data.

In case of synchronized data flow, the TRANSMIT state is left after one frame is transmitted, because READY always drops after the first transmitted bit. Transmit FSM transitions through IDLE and WAIT states before retransmitting, when READY rises.

In case of pipelined data flow, transmit FSM remains in TRANSMIT state as long as READY = 1, and transmission goes on, always clocking data from the appropriate [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register, as selected by arbitration. Transmission is stopped by the condition READY = 0, forcing FSM to go into IDLE state. READY must not switch during the last 8 nominal bit times.

### 23.10.4.8.6 Transmission Exceptions

There are no transmission errors. Reception of READY = 0 in the last 8 bits of frames is not flagged. The DATA ACCEPTED interrupt is used to inform software that the [HST\\_BUFFER\\_Pp\\_CHN\\_i\[31:0\]](#) DATA bit field is empty and to request more data.

### 23.10.4.9 HSI Wake Generator

The WAKE line is used to create a wake-up event for the external module that interfaces with HSI before a data transfer through the HSI serial interface.

The 16 bits (1 per HSI channel) of the [HSI\\_Pp\\_WAKE\[15:0\]](#) WAKE\_CHI bit field are ORed together to drive the WAKE line, as shown in [Figure 23-225](#).

Figure 23-225. HSI\_Pp\_WAKE Control in Case of Managed Wake

hsi-011

The wake generator can be managed by software operations or automatically by hardware. If the wake generator is not managed, the WAKE signal is driven to 0 and the remote transmitter must wake itself upon activity detection on the DATA and FLAG lines.

#### 23.10.4.9.1 Software Management of HSI Wake Generator

Software can get the responsibility to use and manage those bits to create and release wake-up events consistently with HSI use.

Because the [HSI\\_Pp\\_WAKE\[15:0\]](#) WAKE\_CHI bit field can be managed by different threads/processors, this mechanism allows independent bit management by each thread. Without locking the [HSI\\_Pp\\_WAKE](#) register (as a read-modify-write does), it avoids one thread to overwrite the register change made by another thread. Each bit of the [HSI\\_Pp\\_SET\\_WAKE\[15:0\]](#) HSI\_SET\_WAKE\_CHI bit field is owned by one thread at a time.

- The thread can set this bit by setting the corresponding bit of the [HSI\\_Pp\\_SET\\_WAKE\[15:0\]](#) HSI\_SET\_WAKE\_CHI bit field to 1. This sets only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).
- The thread can clear this bit by setting the corresponding bit of the [HSI\\_Pp\\_CLEAR\\_WAKE\[16:0\]](#) HSI\_HSI\_CLEAR\_WAKE\_CHI bit field to 1. This clears only this bit, thus leaving the other bits unchanged (no need of a read-modify-write).

#### 23.10.4.9.2 Automatic Management of HSI Wake Generator

The wake generator is automatically managed when there is a transmission to be performed. When data are waiting for transmission in a FIFO TX, the hardware sets the corresponding bit of the [HSI\\_Pp\\_WAKE\[15:0\]](#) WAKE\_CHI bit field, and this raises the WAKE signal on port *p*. Then WAKE is deasserted by the first occurrence of one event between a fixed time-out from the end of the last transfer, a transition to IDLE in idle-req protocol, a software clear of register.

### 23.10.4.10 FIFO Subsystem

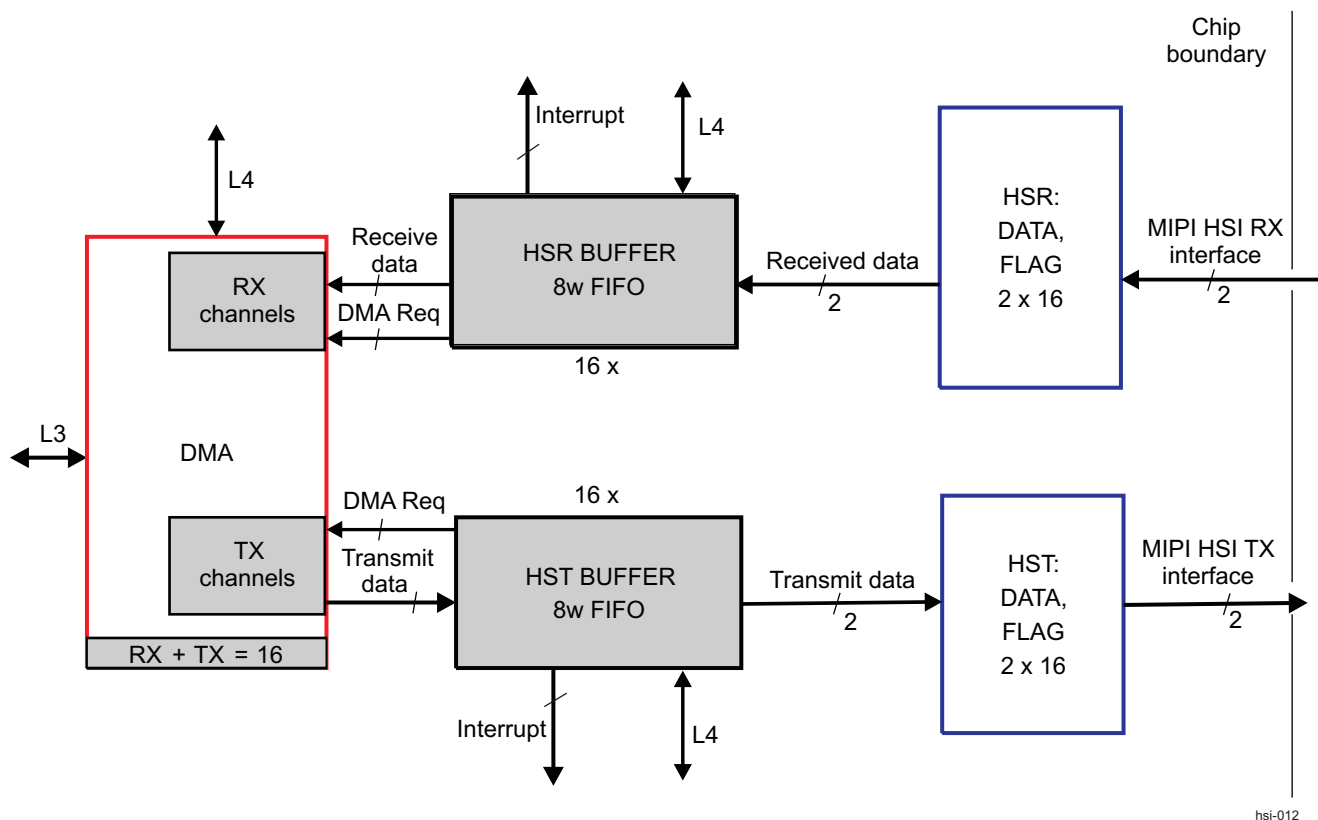

The FIFO subsystem allows temporary buffering while receive data is transferred from the receiver through DMA or the L4 interconnect to main memory, and the storing of transmit data read in main memory through DMA (or written by L4) before transmitting it. The FIFO depth is  $8 \times 32$ -bit words for each channel, yielding a total size of 1KB with 16 bidirectional channels.

RX FIFOs are clocked by interconnect clock, TX FIFOs are clocked by undivided functional clock.

#### 23.10.4.10.1 FIFO Subsystem Architecture

Figure 23-226 shows the overall FIFO architecture.

**Figure 23-226. Overall FIFO Architecture**

hsi-012

There are 16 DMA channels available. They can be used for RX or TX in any combination; direction is programmable.

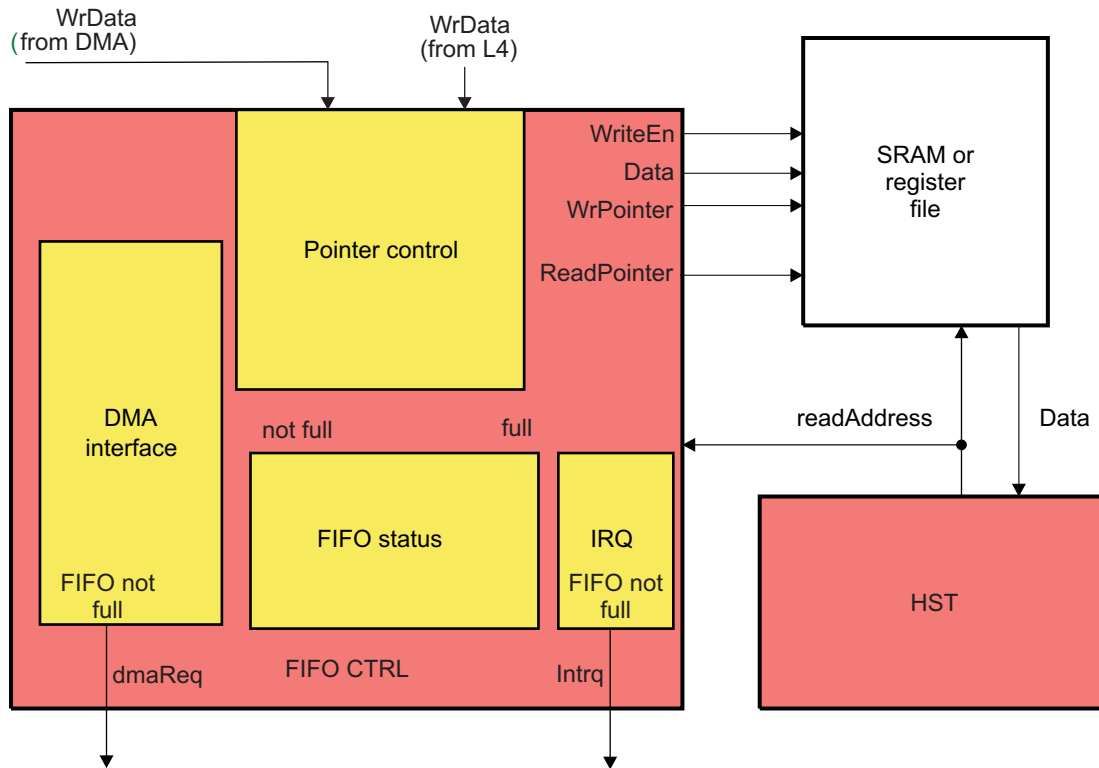

There are 16 RX FIFOs and 16 TX FIFOs. Not all FIFOs can be served by DMA, but all RX FIFOs (or else TX FIFOs) can be served by DMA, if needed. The other FIFOs, if used, must be read/written through the L4\_CFG interconnect.

Both HSI ports provide up to  $16 \times 2$  logical channels. This means that only one half of the HSI logical channels can be accommodated on the existing FIFOs. The others must not be used, and their use must flag an error. The 16 `HST_MAPPINGf` or `HSR_MAPPINGf` registers specify which HSI logical channel number is allowed to be received on RX FIFOs and/or fed for transmission by TX FIFOs. There is one mapping register for transmission and one for reception. Any attempt to transmit or process received data on HSI logical channels not previously mapped on mapping registers results in an error. In other words, some header values (bits 35 to 32) are not allowed at any given time, and generate an error when received. Software must ensure that the remote side sends payload on the allowed logical channels, specified by header values.

23.10.4.10.2 Transmit FIFO Architecture

Figure 23-227 shows the transmission FIFO architecture.

Figure 23-227. Transmission FIFO Architecture

hsi-013

The FIFO controller flags the condition of "room available in FIFO" or "FIFO not full" at any time when FIFO can host new data for transmission. This condition raises an interrupt request and a DMA request, if enabled. A programmable threshold in the corresponding `HST_MAPPING[13:10] THRESHOLD` bit field reduces the number of requests ( they can be sent only when four words can be written in FIFO). The default value for the threshold is 0x0 (that is, a request rises as soon as one word can be written in FIFO). See [Table 23-810](#).

Table 23-810. Threshold for Transmit FIFO Interrupt/DMA Request

HST_MAPPING[13:10] THRESHOLD	Number of Words in FIFO	Request
0 (legacy default)	Less than 8	Yes
1	Less than 1	Yes
2	Less than 2	Yes
3	Less than 3	Yes
4	Less than 4	Yes
5	Less than 5	Yes
6	Less than 6	Yes
7	Less than 7	Yes
8	Less than 8	Yes
9 to 15	Any	No

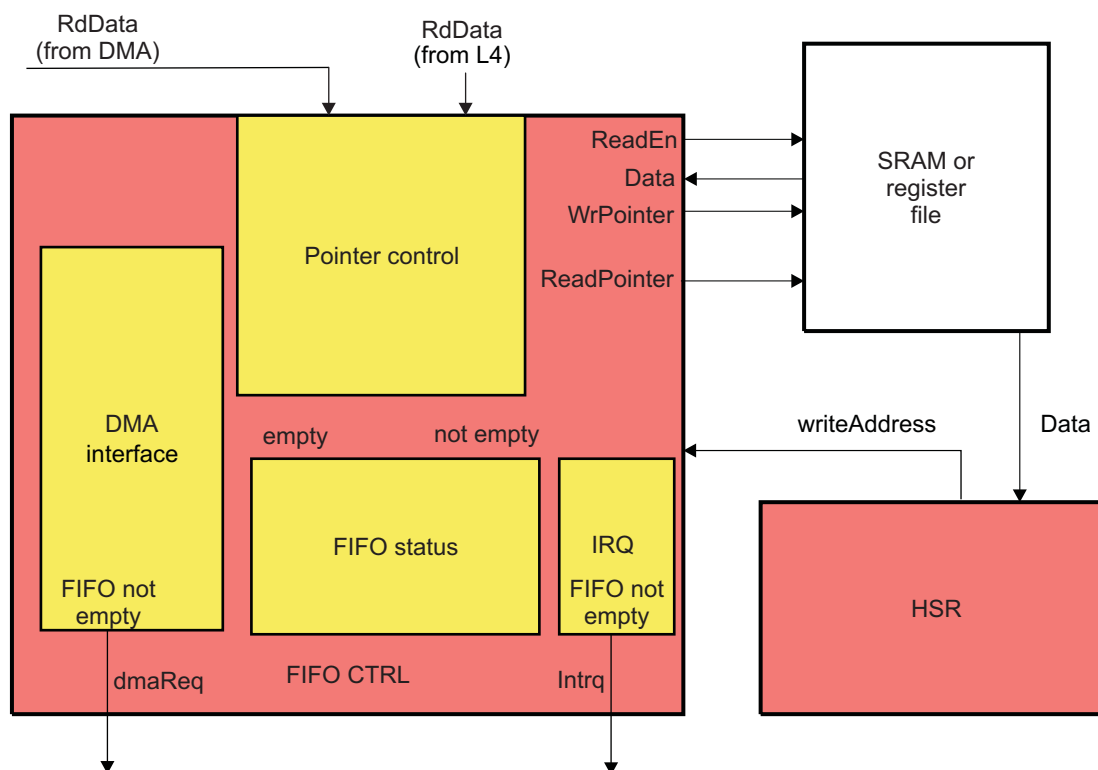

FIFO can be written by DMA and the L4 interconnect configuration port, but the L4 interconnect has fixed priority at any time. Software controls correct access. No hardware mechanism is provided to analyze and block concurrent operation, nor is any hardware control provided on reprogramming DMA registers during a transfer in which they are involved.

The address of FIFO is the corresponding [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register address. The FIFO controller generates the RAM addresses; namely, it manages the write pointer when DMA or the L4 interconnect access the [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) address and it manages the read pointer when HST needs a data to transmit.

### 23.10.4.10.3 Receive FIFO Architecture

Figure 23-228 shows the reception FIFO architecture.

**Figure 23-228. Reception FIFO Architecture**

FIFO controller flags the condition of "unread data in FIFO" or "FIFO not empty" at any time when a FIFO hosts new data, received and not read. This condition can be simply the misalignment of the read pointer and write pointer. The condition raises an interrupt request and a DMA request, if enabled. The [HSR\\_MAPPING](#)[13:10] WORDS bit field informs software how many words must be read.

Unlike transmission, it is not possible here to filter requests through a threshold on the number of received words. If such a threshold is bigger than one, and a last single word is received after the last read, software is unaware that more data waits to be read.

The address of FIFO is the corresponding [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register address. The FIFO controller generates the RAM addresses; namely, it manages the write pointer when HSR has received data, and it manages the read pointer when DMA or the L4 interconnect access the [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) register.

#### **23.10.4.10.4 FIFO Addressing**

From a software point of view, a FIFO is seen at a single address, the corresponding [HST\\_BUFFER\\_Pp\\_CHN\\_i](#) or [HSR\\_BUFFER\\_Pp\\_CHN\\_i](#) register address. The [HST\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) or [HSR\\_SWAPBUFFER\\_Pp\\_CHN\\_i](#) register address is also provided to invert data endianness with byte granularity. FIFO overflow in RX is extremely unlikely, because of the large difference in HSI and L3 interconnect bit rate. However, if this occurs, the hardware prevents any loss of data by deasserting (setting to 0) the READY signal to the remote transmitter. FIFO overflow in TX is not flagged and must be avoided by software drivers.

#### **23.10.4.11 Error Reporting**

##### **23.10.4.11.1 Detection of Errors**

Error detection on the module is limited to the physical layer. No data corruption is checked, and no error is flagged as long as the receiver and transmitter agree on frame boundaries. Because clocking and data are recovered from alternate edges on the DATA and FLAG signals, three kinds of error can appear:

- Simultaneous edges
- Missing edges
- Additional edges

##### **23.10.4.11.1.1 Simultaneous Edges**

The transmitter is not supposed to produce simultaneous edges on the DATA and FLAG signals, but they can appear if the transmission rate is far higher than the receiver can handle. Given to the sampling protocol, this event may introduce errors in sampled data. Detecting this error is not easy, because the recovered clock is also affected, and in some configurations no other clock is available. One bit is available in the [HSR\\_ERROR\\_Pp](#) register, to report any hardware abnormal condition in data reception.

##### **23.10.4.11.1.2 Missing Edges**

Missing edges result in missing clock cycles, thus causing the receiver to get less data than expected on a given frame.

In synchronized flow, when the transmit side has completed transmission, the receiver side is still waiting for more data, and does not raise READY, thus stopping the transmitter from going on with more frames. A frame time-out counter (see [Section 23.10.4.11.2.1, Frame Time-Out Counter](#)) is used to escape this deadlock condition.

In pipelined flow, when the transmit side has completed transmission and has more data to transmit, the receiver accepts and processes this data as if they were part of the previous frame. Frame synchronization is then lost. It may randomly resume when in frame mode, as zeroes at the end of a frame are automatically discarded. But even in this case, a number of frames may be lost or corrupted. When in stream mode, no self-recovery is ever possible, and synchronization is lost forever. A frame burst counter (see [Section 23.10.4.11.2.3, Frame Burst Counter](#)) is used to limit the number of these potentially corrupted frames, simply by limiting the number of frames a transmitter can send back-to-back in a pipelined mode. A tailing bit counter (see [Section 23.10.4.11.2.2, Frame Tailing Bit Counter](#)) is used to check that the receiver and transmitter agree on being at the end of frame.

##### **23.10.4.11.1.3 Additional Edges**

Additional edges result in additional clock cycles, thus causing the receiver to get more data than expected on a given frame.

In synchronized flow, when the receive side thinks the frame is over, the transmitter keeps sending data until the end of frame is reached. In frame mode, if these additional bits are all 0s, they are discarded by the receiver, the transmission stops, and the receiver raises READY when it is available to receive a new frame. The transmit side starts a new frame and synchronization is recovered. But if at least one of the additional bits is set to 1, this can misguide the receiver that a new frame has already started and READY

stays at 0. The transmit side stops, waiting for  $READY = 1$ , a never occurring condition, because the receiver has lost synchronization. In this case, the link is stuck. This is also the case in stream mode, when the receiver wrongly thinks that a new frame is started, so it is not available to receive a full new frame, and it does not set  $READY = 1$ . A frame time-out counter (see [Section 23.10.4.11.2.1](#), *Frame Time-out Counter*) is used to escape this deadlock condition.

### 23.10.4.11.2 Error Counters

Clocks for these three counters are provided through a division of the functional clock. These counters can be set to a value and can be stopped when some events occur. Events flag errors and set a corresponding bit in the [HSR\\_ERROR\\_Pp](#) register.

#### 23.10.4.11.2.1 Frame Time-Out Counter

This counter is clocked by the functional clock, divided by the factor specified in the [HSR\\_DIVISOR\\_Pp\[7:0\]](#)  $RX\_RATE\_DIV\_VAL$  bit field, to provide a clock at receive bit rate. Receive bit rate is always communicated by the remote transmitter through the protocol layer. This counter starts when the first bit of the frame is found and stops when 36 (or 37 depending on the mode) bits are correctly received by the receiver. If the counter overflows, an error is generated (the [HSR\\_ERROR\\_Pp\[1\]](#) FTE bit is set to 0). In OPP reduction of the functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when the receive rate is outside the full error detection rate range.

#### 23.10.4.11.2.2 Frame Tailing Bit Counter

This counter can be clocked by the same clock as the frame time-out counter, which has the receiver bit rate frequency. It starts after the last bit of a frame is received, and  $READY = 0$ ; in pipelined flow, this counter is started only after the end of the last frame received. No event stops the counter, except its own overflow. It counts up to 8. An error is logged (the [HSR\\_ERROR\\_Pp\[4\]](#) TBE bit is set to 0) if a 1 bit is received in frame mode before counter overflow, or any bit is received in stream mode before counter overflow. In OPP reduction of functional clock only (receive side kept in fixed voltage domain), software can decide to reduce either the division factor for the clock, or the count, to use a clock consistent with receive rate, or a reduced count of a slower clock. This is transparent for hardware. This counter is not started when receive rate is outside the full error detection rate range.

#### 23.10.4.11.2.3 Frame Burst Counter

Differently from previous counters, this counter is clocked by a frame-sync signal obtained directly by received data. Its goal is to reduce the number of contiguous frames sent in pipelined flow. As explained in [Section 23.10.4.11.1](#), *Detection of Errors*, in some cases after missing/additional clock cycles, synchronization is lost and these pipelined frames can be corrupted. Software sets the count value, which can be as high as 256 (no higher values are supported by hardware). If  $READY$  is dropped to 0, for reasons other than counter expiration, the counter is stopped and restarted as soon as transmission resumes. At the end of the count,  $READY$  drops to 0. The tailing bit counter is started, and if it overflows without error detection and the receiver has enough room for another frame,  $READY$  is reset to 1. No error and no interrupt are generated on this counter.

### 23.10.4.11.3 Error Registers

One error register per port is provided to check the error source that issued an interrupt, with more details than the error bit in the interrupt status register.

- The [HSR\\_ERROR\\_Pp\[0\]](#) SIG bit: Signal error bits are kept for legacy reasons, and they can be used for any abnormal situation the hardware wants to flag.
- The [HSR\\_ERROR\\_Pp\[1\]](#) FTE bit: Frame time-out error bits flag the situation when not even a frame has been received in the time corresponding to two or more frames, depending on the FTE counter software setting.
- The [HSR\\_ERROR\\_Pp\[4\]](#) FBE bit: Tailing bit error bits flag the situation when at least one spurious bit is received after the end of a frame, in the time corresponding to two or more bit times.

- The [HSR\\_ERROR\\_Pp\[7\]](#) RME bit: Receive mapping error bits flag the situation when data are received on a channel that is not mapped to any enabled FIFO.
- The [HSR\\_ERROR\\_Pp\[11\]](#) TME bit: Transmit mapping error bits flag the situation when DMA tries to access a FIFO that is not mapped to any logical channel, or is not enabled.

These two registers each have a companion [HSR\\_ERRORACK\\_Pp](#) register, where software must set the corresponding error bit to 1 to clear it.

## 23.10.5 HSI Programming Guide

### 23.10.5.1 HSI Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the HSI module.

#### 23.10.5.1.1 Global Initialization

##### 23.10.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HSI module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HSI.

For more information, see [Section 23.10.3, HSI Integration](#).

**Table 23-811. Global Initialization of Surrounding Modules for HSI**

Surrounding Modules	Comments
PRCM	HSI functional and interface clocks must be enabled. For more information, see <a href="#">Chapter 3</a> .
Control module	Module-specific pad muxing must be set in the control module. For more information, see <a href="#">Chapter 18</a> .
(Optional) Interrupt controller	The Cortex-A9 MPU, Cortex-M3 MPU, or DSP INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU, Cortex-M3 MPU, or DSP subsystem. For information about enabling interrupts, see <a href="#">Chapter 5</a> .
(Optional) Interconnect	For information about the L4 interconnect configuration, see <a href="#">Chapter 13, Interconnects</a> . For information about L3 interconnect configuration, see <a href="#">Chapter 13, Interconnects</a> .

#### 23.10.5.1.1.2 HSI Global Initialization

##### 23.10.5.1.1.2.1 Main Sequence – HSI Global Initialization

This procedure initializes the HSI module after a power-on reset (POR) or software reset.

**Table 23-812. HSI Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform an HSI software reset.	<a href="#">HSI_SYSCONFIG[1]</a> SOFTRESET	0x1
<b>WAIT UNTIL</b> HSI reset is complete.	<a href="#">HSI_SYSSTATUS[0]</a> RESETDONE	= 0x1
Set standby mode configuration.	<a href="#">HSI_SYSCONFIG[13:12]</a> MIDDLEMODE	0x-
Set idle mode configuration.	<a href="#">HSI_SYSCONFIG[4:3]</a> SIDLEMODE	0x-
Clock auto gating.	<a href="#">HSI_SYSCONFIG[0]</a> AUTOIDLE	0x-
Set the transmit data rate.	<a href="#">HST_DIVISOR_Pp[7:0]</a> TX_RATE_DIV_VAL	0x-
(Optional) Enable DMA.	<a href="#">DMA_GCR[0]</a> SWITCH_OFF	0x0

#### 23.10.5.1.2 HSI Operational Modes Configuration

##### 23.10.5.1.2.1 HSI Transmit Mode/Receive Mode

##### 23.10.5.1.2.1.1 Main Sequence – Configure HSI Transmitter

**Table 23-813. HSI Configure HSI Transmitter**

Step	Register/Bit Field/Programming Model	Value
Set the mode.	<a href="#">HST_MODE_Pp[1:0]</a> MODE_VAL	0x-
Set the data flow type.	<a href="#">HST_MODE_Pp[3:2]</a> FLOW_VAL	0x-
Set the hsi_wake line control.	<a href="#">HST_MODE_Pp[4]</a> WAKE_CTRL	0x-
Set the transmission bit rate	<a href="#">HST_DIVISOR_Pp[7:0]</a> TX_RATE_DIV_VAL	0x-
Set the arbitration mode.	<a href="#">HST_ARBMODE_Pp[0]</a> ARB_VAL	0x-
Set the number of active HSI logical channels.	<a href="#">HST_CHANNELS_Pp[4:0]</a> CHAN_NUM_VAL	0x-
Set the TX FIFO threshold.	<a href="#">HST_MAPPINGf[13:10]</a> THRESHOLD	0x-
Associate the TX FIFO to an HSI port.	<a href="#">HST_MAPPINGf[7]</a> PORT_NUMBER	0x-
Associate the TX FIFO to an HSI logical channel.	<a href="#">HST_MAPPINGf[4:1]</a> CH_NUMBER	0x-
Enable the TX FIFO.	<a href="#">HST_MAPPINGf[0]</a> ENABLE	0x-

### 23.10.5.1.2.1.2 Main Sequence – Configure HSI Receiver

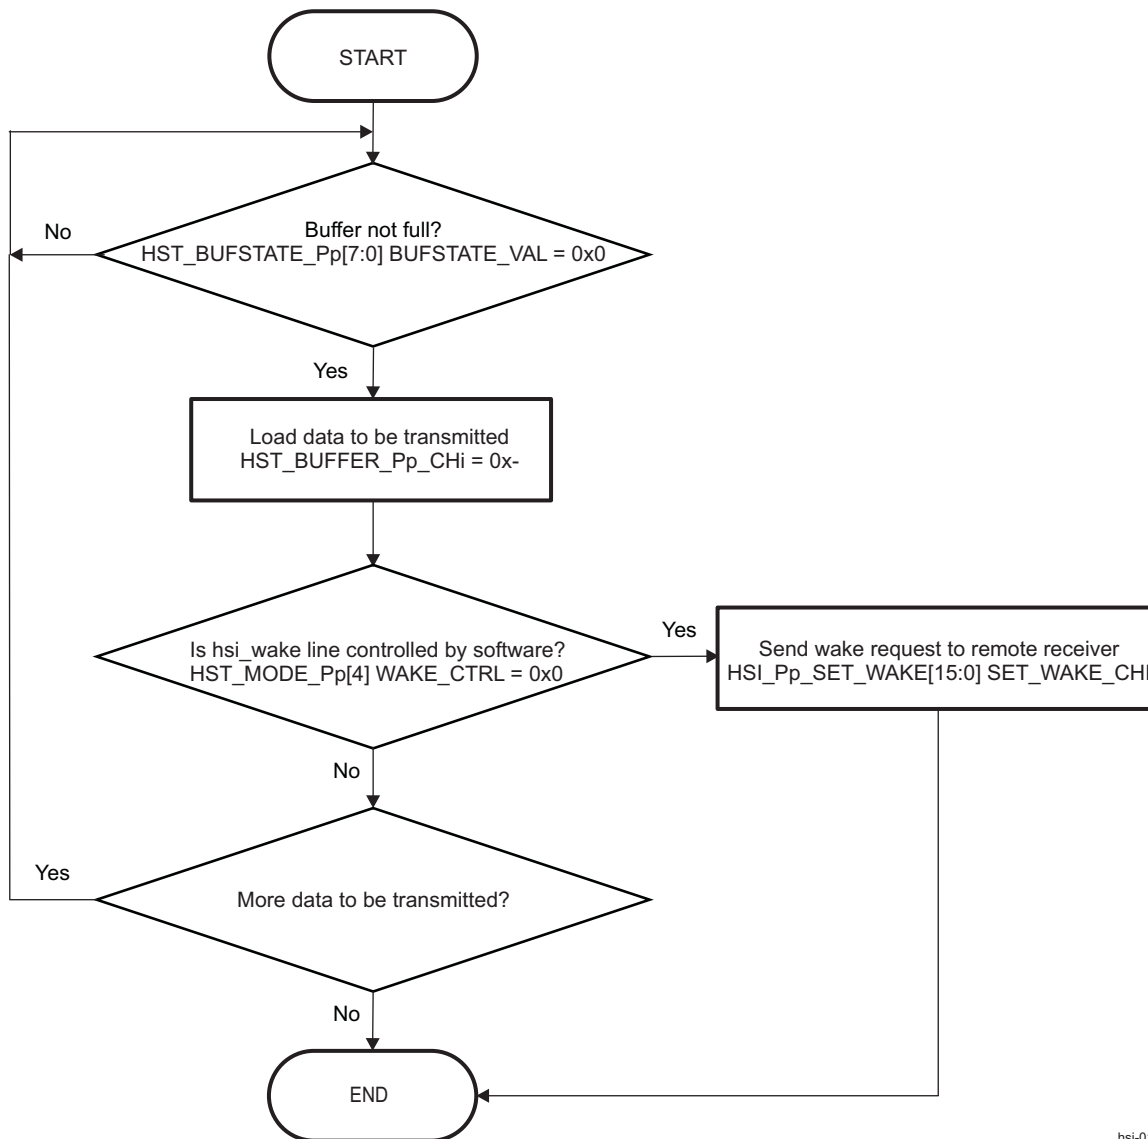

**Table 23-814. HSI Configure HSI Receiver**

Step	Register/Bit Field/Programming Model	Value
Set a clock frequency for the error detection counters.	<a href="#">HSR_DIVISOR_Pp[7:0]</a> RX_RATE_DIV_VAL	0x-
Set the number of active HSI logical channels.	<a href="#">HSR_CHANNELS_Pp[4:0]</a> CHAN_NUM_VAL	0x-
Set the frame timeout error counter.	<a href="#">HSR_COUNTERS_Pp[19:0]</a> FT	0x-
Set the tailing bit error counter.	<a href="#">HSR_COUNTERS_Pp[23:20]</a> TB	0x-
Set the frame burst error counter.	<a href="#">HSR_COUNTERS_Pp[31:24]</a> FB	0x-
Associate the RX FIFO to an HSI port.	<a href="#">HSR_MAPPINGf[7]</a> PORT_NUMBER	0x-
Associate the RX FIFO to an HSI logical channel.	<a href="#">HSR_MAPPINGf[4:1]</a> CH_NUMBER	0x-
Enable the RX FIFO.	<a href="#">HSR_MAPPINGf[0]</a> ENABLE	0x-
Set the mode in receive mode.	<a href="#">HSR_MODE_Pp[1:0]</a> MODE_VAL	0x-
Set the data flow type in receive mode.	<a href="#">HSR_MODE_Pp[3:2]</a> FLOW_VAL	0x-

### 23.10.5.1.2.1.3 Main Sequence – HSI Polling Method

#### 23.10.5.1.2.1.3.1 Sub-sequence – HSI Transmit in Polling Method

[Figure 23-229](#) is a procedure flow chart for HSI transmit in polling method.

### 23.10.5.1.2.1.5 Main Sequence – HSI DMA Mode

#### 23.10.5.1.2.1.5.1 Sub-sequence – DMA Configuration

**Table 23-822. HSI DMA Configuration**

Step	Register/Bit Field/Programming Model	Value
Perform a DMA software reset.	DMA_GRST[0] SWRESET	0x1
<b>WAIT UNTIL</b> DMA reset is complete.	DMA_GRST[0] SWRESET	= 0x0
Set autoidle mode configuration for DMA.	DMA_GCR[3] AUTOGATING	0x1
Configure HSI DMI receiver.	See <a href="#">Table 23-823</a> .	
Configure HSI DMI transmit.	See <a href="#">Table 23-824</a> .	
Enable DMA interrupts.	See <a href="#">Section 23.10.5.1.2.1.5.4</a> .	
Enable DMA channel to start DMA transfer.	DMA_CCR_CSDP_i[23] ENABLE	0x1
<b>WHEN DMA INTERRUPT OCCURS</b>	See <a href="#">Table 23-817</a> .	

### 23.10.5.1.2.1.5.2 Subsequence – DMA Receive Mode

**Table 23-823. Configure DMA Receive Mode**

Step	Register/Bit Field/Programming Model	Value
Set the transfer source to peripheral port.	DMA_CCR_CSDP_i[5:2] SRC	0x9
(Optional) Set the source burst enable.	DMA_CCR_CSDP_i[8:7] SRC_BURST_EN	0x1
Set the transfer destination to memory port.	DMA_CCR_CSDP_i[12:9] DST	0x8
(Optional) Set the destination burst enable.	DMA_CCR_CSDP_i[15:14] DST_BURST_EN	0x1
Set the source addressing mode to constant address.	DMA_CCR_CSDP_i[29:28] SRC_ADD_MODE	0x0
Set the destination addressing mode to post-incremented address.	DMA_CCR_CSDP_i[31:30] DST_ADD_MODE	0x1
Set the source start address.	DMA_CSSA_i[31:0] ADDR	0x-
Set the destination start address.	DMA_CDSA_i[31:0] ADDR	0x-
Set the number of elements in a block.	DMA_CEN_i[15:0] SIZE	0x-

### 23.10.5.1.2.1.5.3 Subsequence – DMA Transmit Mode

**Table 23-824. Configure DMA Transmit Mode**

Step	Register/Bit Field/Programming Model	Value
Set the transfer source to memory port.	DMA_CCR_CSDP_i[5:2] SRC	0x8
(Optional) Set the source burst enable.	DMA_CCR_CSDP_i[8:7] SRC_BURST_EN	0x1
Set the transfer destination to peripheral port.	DMA_CCR_CSDP_i[12:9] DST	0x9
(Optional) Set the destination burst enable to single access.	DMA_CCR_CSDP_i[15:14] DST_BURST_EN	0x1
Set the source addressing mode to post-incremented address.	DMA_CCR_CSDP_i[29:28] SRC_ADD_MODE	0x1
Set the destination addressing mode to constant address.	DMA_CCR_CSDP_i[31:30] DST_ADD_MODE	0x0
Set the source start address.	DMA_CSSA_i[31:0] ADDR	0x-
Set the destination start address.	DMA_CDSA_i[31:0] ADDR	0x-
Set the number of elements in a block.	DMA_CEN_i[15:0] SIZE	0x-

#### 23.10.5.1.2.1.5.4 Subsequence – Enable DMA Interrupts

**Table 23-825. Enable DMA Interrupts**

Step	Register/Bit Field/Programming Model	Value
Enable the DMA channels that shall generate an interrupt to a processor (MPU and/or DSP).	HSI_DMA_M_IRQENABLE[15:0] DMA_EN_CHI and/or HSI_DMA_D_IRQENABLE[15:0] DMA_EN_CHI	0x-
Enable the DMA full-block interrupt event.	DMA_CSR_CCIR_i[5] BLOCK_IE	0x1
Enable the DMA half-block interrupt event.	DMA_CSR_CCIR_i[2] HALF_IE	0x1
Enable the DMA time-out overflow interrupt event.	DMA_CSR_CCIR_i[0] TOUT_IE	0x1

#### 23.10.5.1.2.1.5.5 Subsequence – DMA Interrupt Servicing

**Table 23-826. Event Servicing in DMA Transmit/Receive Mode**

Step	Register/Bit Field /Programming Model	Value
Identify which DMA channel has generated an interrupt.	HSI_DMA_M_IRQSTATUS[15:0] DMA_CHI and/or HSI_DMA_D_IRQSTATUS[15:0] DMA_CHI	0x-
Identify the interrupt event type.	DMA_CSR_CCIR_i[21] BLOCK_IS and/or DMA_CSR_CCIR_i[18] HALF_IS and/or DMA_CSR_CCIR_i[16] TOUT_IS	0x-
Acknowledge DMA global interrupt by setting the relevant bit to 1.	HSI_DMA_M_IRQSTATUS[15:0] DMA_CHI and/or HSI_DMA_D_IRQSTATUS[15:0] DMA_CHI	0x-

#### 23.10.5.1.2.1.6 Main Sequence – HSI Error Reporting

**Table 23-827. Enable HSI Error Interrupts**

Step	Register/Bit Field/Programming Model	Value
Enable error detected interrupt.	HSI_Pp_M_IRQrU_ENABLE[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_ENABLE[24] HSR_ERROR and/or HSI_Pp_M_IRQr_ENABLE[24] HSR_ERROR and/or HSI_Pp_D_IRQr_ENABLE[24] HSR_ERROR	0x1

**Table 23-828. Event Servicing Error**

Step	Register/Bit Field/Programming Model	Value
Read interrupt status register.	HSI_Pp_M_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_M_IRQr_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQr_STATUS[24] HSR_ERROR	0x-
Identify the interrupt event type.	HSR_ERROR_Pp[0] SIG HSR_ERROR_Pp[1] FTE HSR_ERROR_Pp[4] FBE HSR_ERROR_Pp[7] RME HSR_ERROR_Pp[11] TME	0x-
Clear the event by writing 1 into the relevant bit.	HSR_ERRORACK_Pp[0] SIG HSR_ERRORACK_Pp[1] FTE HSR_ERRORACK_Pp[4] FBE HSR_ERRORACK_Pp[7] RME HSR_ERRORACK_Pp[11] TME	0x1
Acknowledge the interrupt by writing 1 into the relevant bit.	HSI_Pp_M_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQrU_STATUS[24] HSR_ERROR and/or HSI_Pp_M_IRQr_STATUS[24] HSR_ERROR and/or HSI_Pp_D_IRQr_STATUS[24] HSR_ERROR	0x1

## 23.10.6 HSI Register Manual

### 23.10.6.1 HSI Instance Summary

Table 23-829 summarizes the HSI instance.

**Table 23-829. HSI Instance Summary**

Module Name	Module Base Address	Size
HSI_TOP	0x4A05 8000	5 KB
HSI_DMA_CHANNELS	0x4A05 9800	1 KB
HSI_PORTS	0x4A05 A000	8 KB

### 23.10.6.2 HSI\_TOP Registers

#### 23.10.6.2.1 HSI\_TOP Register Summary

Table 23-830 summarizes the mapping of the HSI\_TOP registers.

**Table 23-830. HSI\_TOP Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	HSI_TOP Physical Address
HSI_REVISION	R	32	0x0000 0000	0x4A05 8000
HSI_HWINFO	R	32	0x0000 0004	0x4A05 8004
HSI_SYSCONFIG	RW	32	0x0000 0010	0x4A05 8010
HSI_SYSSTATUS	R	32	0x0000 0014	0x4A05 8014

**Table 23-830. HSI\_TOP Registers Mapping Summary (continued)**

## 23.11 High-Speed Multiport USB Host Subsystem

This section describes the HS universal serial bus (USB) host subsystem of the device.

### 23.11.1 High-Speed Multiport USB Host Subsystem Overview

---

**NOTE:** Copyright ©2004, 2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

---

The HS USB host subsystem is composed of:

- HS multiport USB host controller module
- USB TLL module
- Three HSIC digital front end (DFE) modules

The HS USB host subsystem consists of several ports delivered outside the device, with several modes per port. The modes are:

- UTMI+ low pin-count interface (ULPI) for external PHY
- ULPI transceiverless link (TLL)
- Serial TLL
- High-speed interchip (HSIC)

The HS USB host controller module contains two quasi-independent host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) Specification for USB Release 1.1*, is responsible for HS traffic (480 Mbps), over ULPI/USB 2.0 transceiver macrocell interface (UTMI).
- The OHCI controller, based on the *Open Host Controller Interface (OHCI Specification for USB Release 1.0a*, is responsible for full-speed (FS)/low-speed (LS) traffic (12/1.5 Mbps, respectively), over a serial interface.

Each of the three external ports of the HS USB host controller module is owned by one of the controllers (EHCI or OHCI) at a given time. Each port can work in several modes:

- When the port is owned by the OHCI (FS) host, the 6-pin internal serial interface to the TLL is used.
- When the port is owned by the EHCI (HS) host, UTMI internal interface to the TLL, or ULPI to external PHY is used.

For more details on USB controller module internal architecture, see [Section 23.11.4.1, USB Host Controller Functionality](#).

The current subsystem does not support all dynamic USB speed negotiations, as expected from a standard USB host port at the same time. It supports:

- HS-only (with external HS physical layer [PHY]/HS TLL mode HSIC) on the EHCI
- FS-/LS-only (with external FS PHY/FS TLL mode) on the OHCI

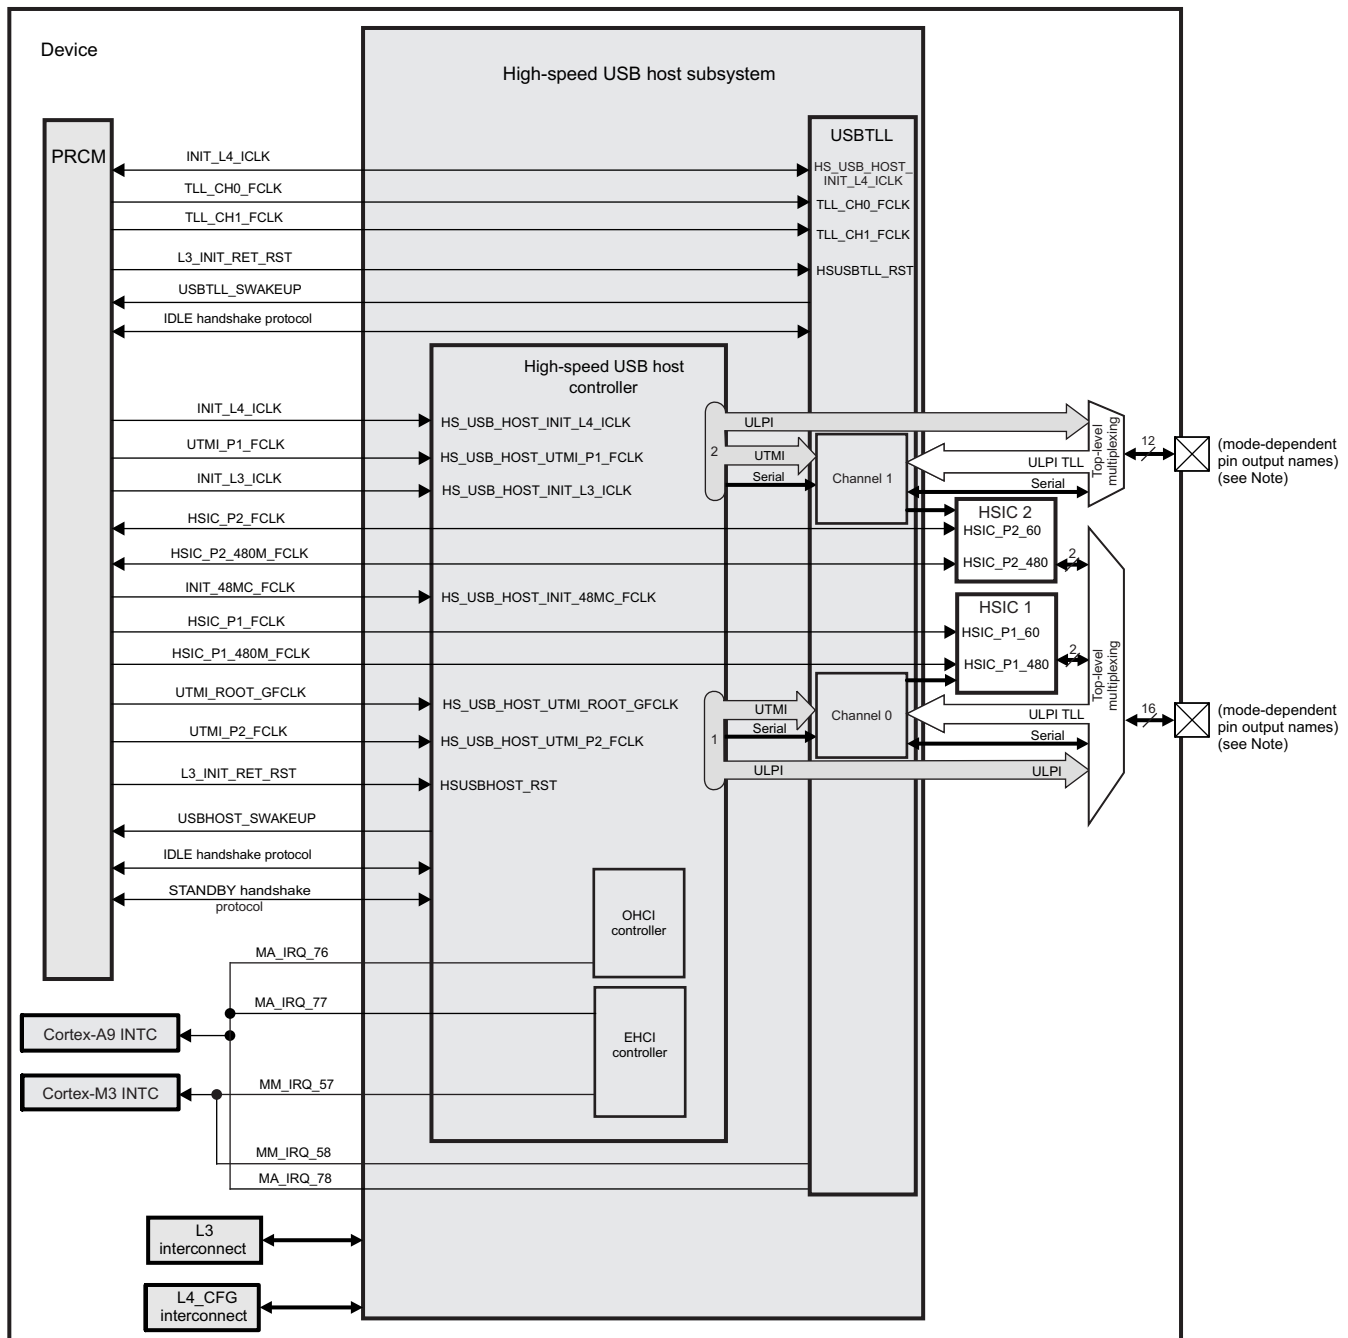

The USB TLL module is the adapter on the host ports. It consists of two channels that are seen as emulating a pair of back-to-back PHYs and has:

- UTMI port, connected to the host controller module
- ULPI port, connected to a ULPI peripheral

The three HSIC DFEs plug into the UTMI port of the host controller module and control HSIC-capable bidirectional I/O drivers driving the HSIC lines (strobe/data).

[Figure 23-232](#) shows the HS USB host subsystem.

Figure 23-232. HS USB Host Controller

usb-006

NOTE: For more information about output pin names in different modes, see [Section 23.11.2.1, ULPIs](#); [Section 23.11.2.2, FS/LS Serial Interfaces](#); and [Section 23.11.2.3, HSIC Interface](#).

### 23.11.1.1 Main Features

The HS multiport USB host subsystem supports the following features:

- HS USB host controller:
  - One initiator on level 3 (L3)
  - One target on level 4 (L4)
  - Two IRQs

- No DMA request
- Implements a USB 2.0 HS host controller:
  - HS (480 Mbps) communication with HS USB peripherals or hubs
  - FS (12 Mbps) communication with FS USB peripherals or hubs
  - LS (1.5 Mbps) communication with LS USB peripherals
- Support for suspend, resume, remote wakeup
- Two downstream ports (2-port root hub, with each port supporting UTMI, ULPI, and serial interface)
- Heterogeneous port configuration (that is, different HS/FS PHYs with different clocking methods on different ports, supported simultaneously)
- Single FS host controller, compliant with OHCI software application programming interface (API), per-port power switching support
- Interface with UTMI PHYs (that is, the TLL module) on all ports
  - 8-bit data path
  - Synchronous (on-chip) interface, independent clock input per port (that is, the TLL module provides a clock to the host controller and to the remote USB controller).
  - HSIC front-end (after appropriate internal configuration)
- Interface with ULPI PHYs (transceivers) on all ports
  - 8-bit bidirectional data bus (SDR mode)
  - 12-pin interface
  - Independent clock input per port (ULPI PHY in output mode)
  - Supports only HS data transactions

**CAUTION**

The HS USB host subsystem can support only the external charge pump of PHY (no support of internal charge pump for ULPI PHY).

- Interconnect initiator for built-in DMA operation of EHCI/OHCI
- Interconnect target for configuration
- Link power management (LPM) support in OHCI and EHCI hosts
- Hardware save-and-restore (SAR) feature of the hardware context of the suspended host
- USBTLL module:
  - One interconnect target on L4
  - One IRQ
  - No DMA request
  - HS USB ports and each of them has four ports (A to D):
    - Port A: Host module UTMI+ port. Connects to the local link controller (host module). The UTMI "local" port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the other, "remote" ports. The port complies with UTMI+ version 1.0 and supports:
      - 8-data-bit, UTMI (HS/FS-capable)
      - UTMI+ L3 extensions
      - Vcontrol/Vstatus (from UTMI)
      - Serial FS 6-pin mode
    - Port B: Link-side UTMI+ port. Connects to HSIC front-end module.
    - Port C: PHY-side ULPI slave port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
      - SDR ULPI mode (8-bit data width)

- Port D: Serial multimode port.
  - Supports 6-pin unidirectional and 4-/3-/2-pin bidirectional modes
  - All modes are supported for TLL or PHY interface configuration, except 2-pin mode (which is TLL-only).
  - Supports sideband signals (pullup/down control, speed/suspend enable, etc.)
- HSIC module: Converts UTMI into HSIC standard (2-wire TLL HS protocol)

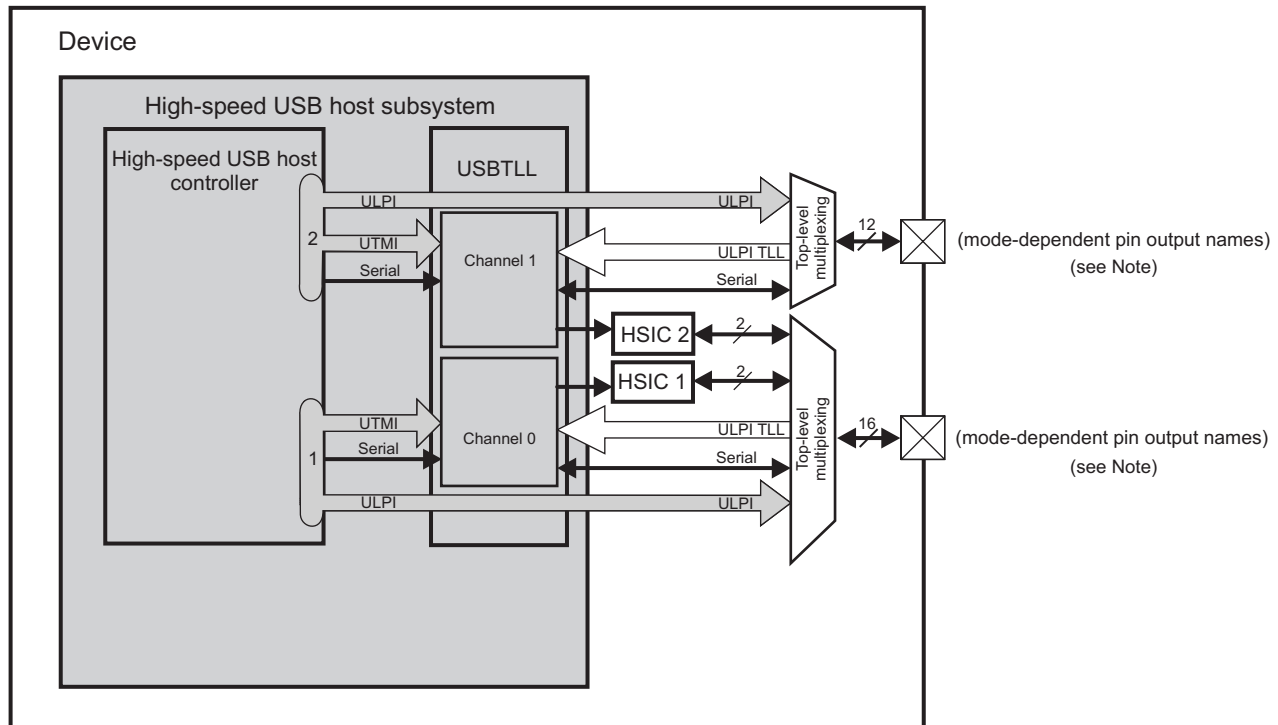

### 23.11.2 HS Multiport USB Host Subsystem Environment

The HS USB host subsystem provides three kinds of interfaces for connection:

- ULPis for HS data transactions (up to 480 Mbps) (see [Section 23.11.2.1, ULPis](#))
- Serial interfaces, using the USBTLL module, for FS and LS data transactions (up to 12 Mbps) (see [Section 23.11.2.2, FS/LS Serial Interfaces](#))
- HSIC interface to two HSIC lines over HSIC-capable I/O drivers (see [Section 23.11.2.3, HSIC Interface](#))

Figure 23-233 is an overview of the environment of the HS USB host subsystem.

Figure 23-233. HS Multiport USB Host Subsystem Environment

usb\_swpu140-072

NOTE: For more information about output pin names in different modes, see [Section 23.11.2.1, ULPis](#); [Section 23.11.2.2, FS/LS Serial Interfaces](#); and [Section 23.11.2.3, HSIC Interface](#).

NOTE: The two ports are configured independently and can be in different modes.

For more information how the pins are multiplexed, see [Section 18.4.8, PAD Functional Multiplexing and Configuration](#).

#### 23.11.2.1 ULPis

The HS USB host subsystem supports the following configurations with the ULPis:

- External USB transceiver:

- ULPis: 12-pin/8-bit data SDR version
- TLL:
  - SDR ULPI mode (12-pin/8-bit data width)

The HS USB host subsystem supports USB ports that use the ULPI mode to connect to an off-chip HS ULPI transceiver (12-pin/8-bit data SDR mode) for data transactions (up to 480 Mbps). FS and LS are not supported over the ULPI.

The device supports TLL logic interfaces on its ports in ULPI TLL interface mode. TLL modes enable glueless interconnect to another USB device port.

The external USB transceiver ULPis and ULPI TLL interfaces cannot be used together on the same port. It is possible for one port to use ULPI and the other port to use ULPI TLL.

Figure 23-234 and Figure 23-235 show typical applications using the HS USB host subsystem with ULPI and the ULPI TLL interface, respectively.

**Figure 23-234. External USB Transceiver ULPis**

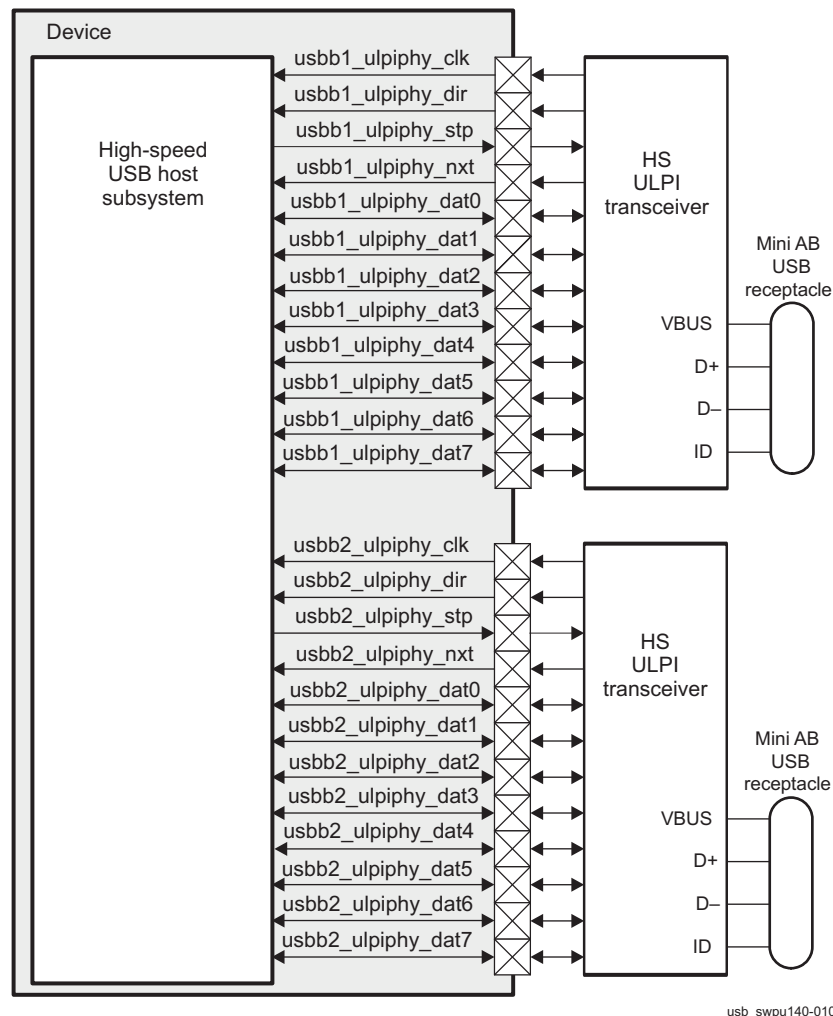

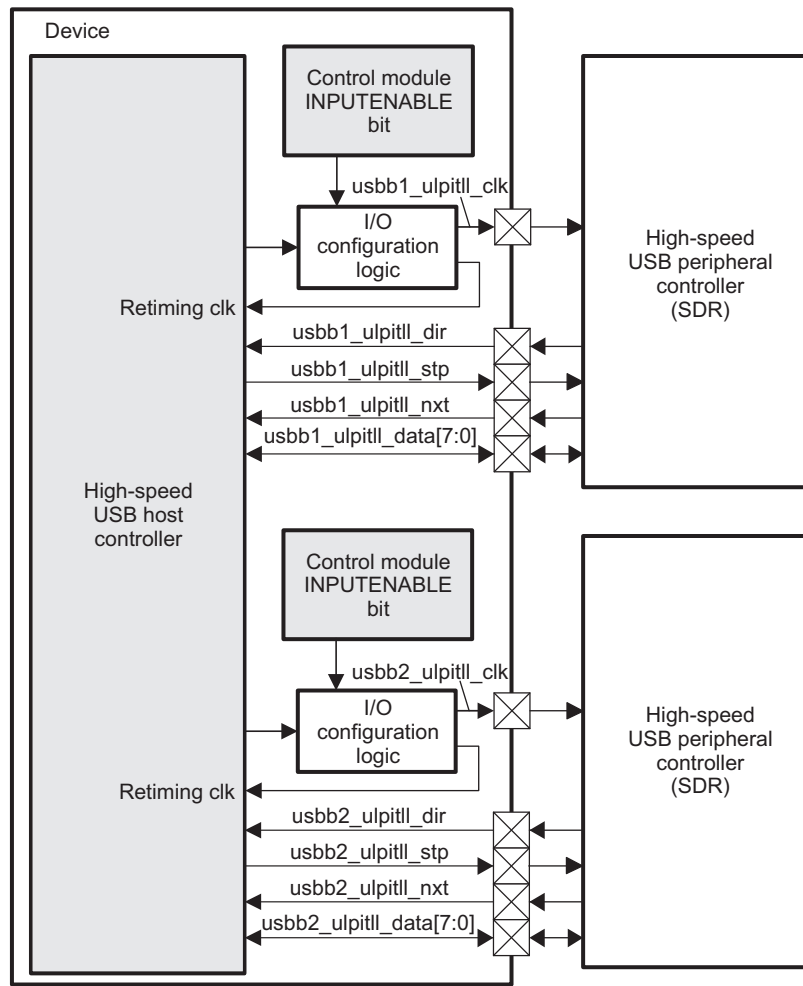

Figure 23-235. ULPI TLL Interfaces

usb-032

The 12-pin ULPI uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode).

**NOTE:** The recommended slew rate is not set by default. The slew rate must be set in the CONTROL\_USBB\_HSIC registers. For more information, see [Table 18-88](#) and [Table 18-89](#).

### 23.11.2.1.1 Transceiver Interface Configuration in ULPI Mode

The HS USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI mode.

[Figure 23-236](#) shows USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

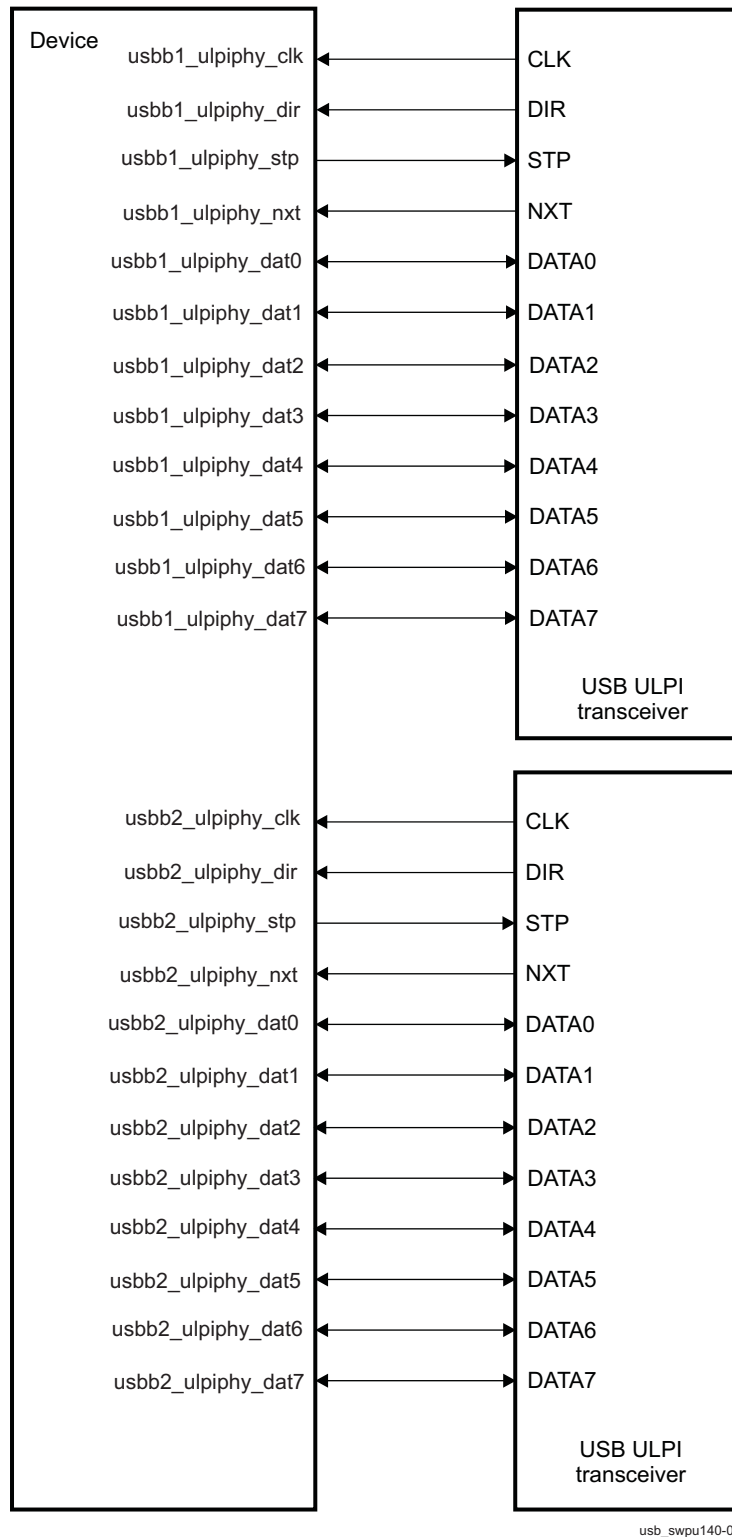

**Figure 23-236. ULPis – 12-Pin/8-Bit Data SDR Version**

Table 23-943 describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI mode.

**Table 23-943. ULPI – 12-Pin/8-Bit Data SDR Version I/O Description**

### 23.11.2.1.2 TLL Interface Configuration in ULPI Mode

The HS USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

[Figure 23-237](#) shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

**Figure 23-237. ULPI TLL Interfaces – 12-Pin/8-Bit Data SDR Version**

[Table 23-944](#) describes the I/O pins of the USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

**Table 23-944. ULPI TLL Interfaces – 12-Pin/8-Bit Data SDR Version I/O Description**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value

<sup>(2)</sup> This signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

### 23.11.2.2 FS/LS Serial Interfaces

The HS USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver (see [Section 23.11.2.2.3, External USB Transceiver Interface Configurations in Serial Modes](#))
  - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL (see [Section 23.11.2.2.4, TLL Interface Configurations in Serial Modes](#))
  - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

#### CAUTION

Only FS and LS data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

Whether in TLL or external transceiver configuration, the serial interface follows the same principles: it is limited to FS/LS, and HS requires a parallel interface.

### 23.11.2.2.1 Encoding in Serial Mode

#### 23.11.2.2.1.1 Unidirectional

When an external USB transceiver is connected to the device and is used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 23-945](#) is used.

**Table 23-945. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D–.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D– when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D–
			0	0	0	0	1
			0	1	0	1	0
			0	X	1	0	0
1	X	X	Undriven	Undriven			
RCV	Input	Output	Output from transceiver differential receiver				
			D+	D–	RCV		
			0	0	X		
			0	1	0		
			1	0	1		
1	1	X					
DP	Input	Output	Output from transceiver single-ended D+ signal receiver				
			D+	DP			
			0	0			
1	1						
DM	Input	Output	Output from transceiver single-ended D- signal receiver				
			D–	DM			
			0	0			
1	1						

When an external USB transceiver is connected to the device and is used in 6-pin unidirectional DP/DM encoding mode, the encoding described in [Table 23-946](#) is used.

**Table 23-946. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D–.				
DAT and SE0	Output	Input	Controls the values output by the USB transceiver on D+ and D– when TXEN is low; ignored when TXEN is high.				
			TXEN	DAT	SE0	D+	D–
			0	0	1	0	1
			0	1	0	1	0
			0	0	0	0	0
1	X	X	Undriven	Undriven			

**Table 23-946. Signaling Between HS USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling) (continued)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description		
RCV	Input	Output	Output from transceiver differential receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
1	1	X			
DP	Input	Output	Output from transceiver single-ended D+ signal receiver		
			D+	DP	
			0	0	
1	1				
DM	Input	Output	Output from transceiver single-ended D-signal receiver		
			D-	DM	
			0	0	
			1	1	

**23.11.2.2.1.2 Bidirectional**

When an external USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 23-947](#) is used.

**Table 23-947. Signaling Between HS USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.				
DAT and SE0	Output	Input	When TXEN is low, the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0.				
			TXEN	DAT	SE0	D+	D-
			0	0	0	0	1
	1	0	0	1	0		
	X	1	0	0	0		
	Input	Output	TXEN	D+	D-	DAT	SE0
			1	0	0	0	1
			0	1	0	0	0
			1	0	1	1	0
	1	1	Undefined	0			

**NOTE:** The device does not support 3-wire bidirectional signaling using DP/DM signals.

When an external USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 23-948](#) is used.

**Table 23-948. Signaling Between HS USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description
TXEN	Output	Input	When low, the USB transceiver drives D+ and D-.

**Table 23-948. Signaling Between HS USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling (continued)**

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description			
DM	Output	Input	Value driven to or received from D–			
			TXEN	DM	D–	
			0	0	0	
				0	1	1
	Input	Output	TXEN	D–	DM	
			1	0	0	
1			1	1		
DP	Output	Input	Value driven to or received from D+			
			TXEN	DP	D+	
			0	0	0	
				0	1	1
	Input	Output	TXEN	D+	DP	
			1	0	0	
1			1	1		
RCV	Input	Output	Output from transceiver differential receiver			
			D+	D–	RCV	
			0	0	X	
			0	1	0	
			1	0	1	
			1	1	X	

### 23.11.2.2.2 Sideband Signals for Serial Modes

Serial interfaces carry only the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D- pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end, etc.)
- Sideband signal implementations: Dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I<sup>2</sup>C) UART, etc.)

Figure 23-238 and Figure 23-239 show system integration for sideband signals for two logically identical USB connections: one in transceiver configuration and one in TLL configuration. Although the sideband (purple) arrows are oriented from the controller to the transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from the controller to the transceiver [control] and from the transceiver to the controller [status]).

Figure 23-238 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- The software-driven VBUS reporting procedure is described in Section 23.11.4.2.6.1.1, *VBUS Management in Serial Transceiver Configurations*.

Figure 23-238. Serial Interface Sideband Integration – Transceiver Configuration

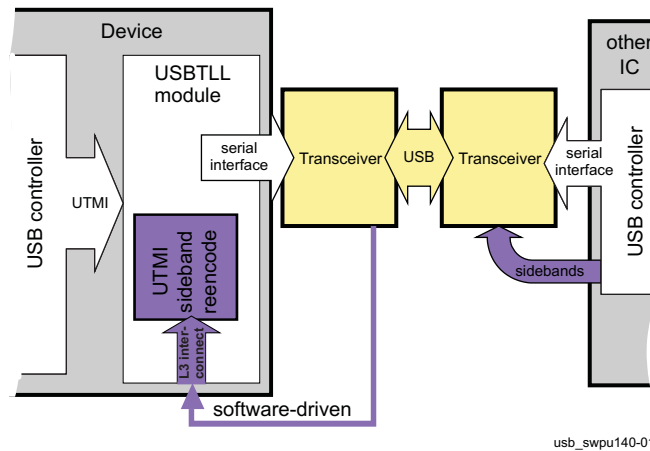

Figure 23-239 shows the TLL configuration, where both transceivers are emulated inside the USBTLL module.

- The transceiver of the local controller (left side of the figure) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right side of the figure) must communicate with its controller, which is on another IC. This is done in two ways:
  - The sideband input signals at the TLL module boundary (tllpuen, tlldrvbus, tllvbusvalid, etc.)
  - The software-driven VBUS control procedure described in [Section 23.11.4.2.6.2.2, VBUS Emulation in Serial TLL Modes](#))

Figure 23-239. Serial Interface Sideband Integration – TLL Configuration

### 23.11.2.2.3 External USB Transceiver Interface Configurations in Serial Modes

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the HS USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the HS USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to two external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the HS USB subsystem in serial interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided by additional signals or through an I<sup>2</sup>C link.

The following subsections describe the transceiver interface modes supported by the HS USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of the USB lines (D+/D-).

### 23.11.2.2.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

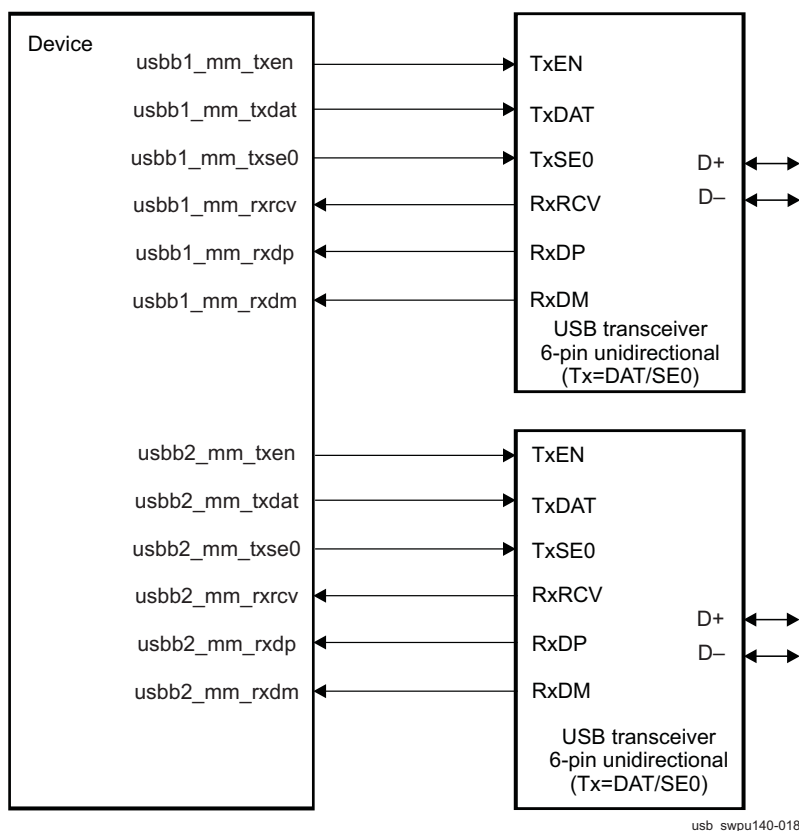

The 6-pin modes are the "natural" transceiver interface modes for the FS transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 and DP/DM.

When an external USB is connected to the device and is used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in [Table 23-945](#) is used.

[Figure 23-240](#) shows a USB port using DAT/SE0 encoding.

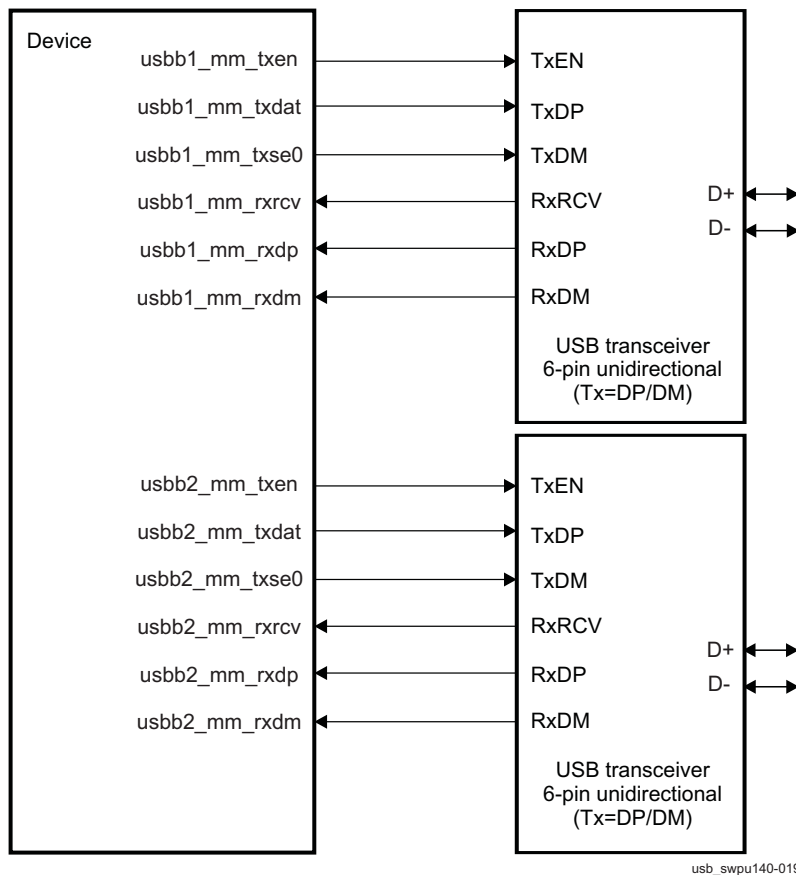

**Figure 23-240. 6-Pin Unidirectional Using DAT/SE0 Signaling**

When a USB is connected to the device and is used in 6-pin unidirectional DP/DM signaling mode, the signaling described in [Table 23-946](#) is used.

[Figure 23-241](#) shows a USB port using DP/DM encoding.

**Figure 23-241. 6-Pin Unidirectional Using DP/DM Signaling**

usb\_swpu140-019

**23.11.2.2.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin**

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

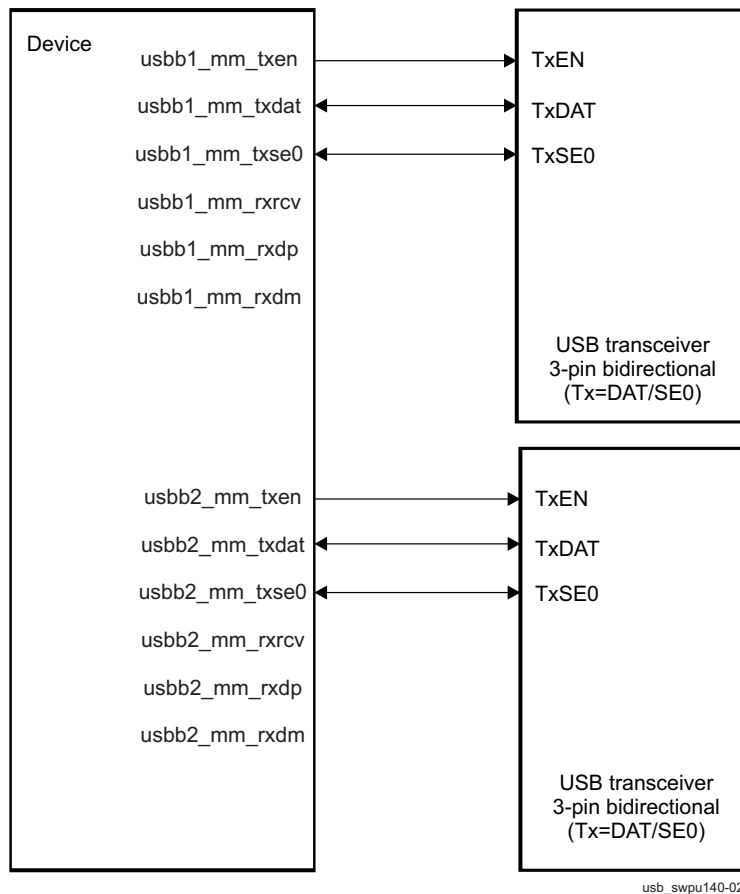

The signaling described in Table 23-947 is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

---

**NOTE:** The device does not support 3-wire bidirectional signaling using DP/DM signals.

---

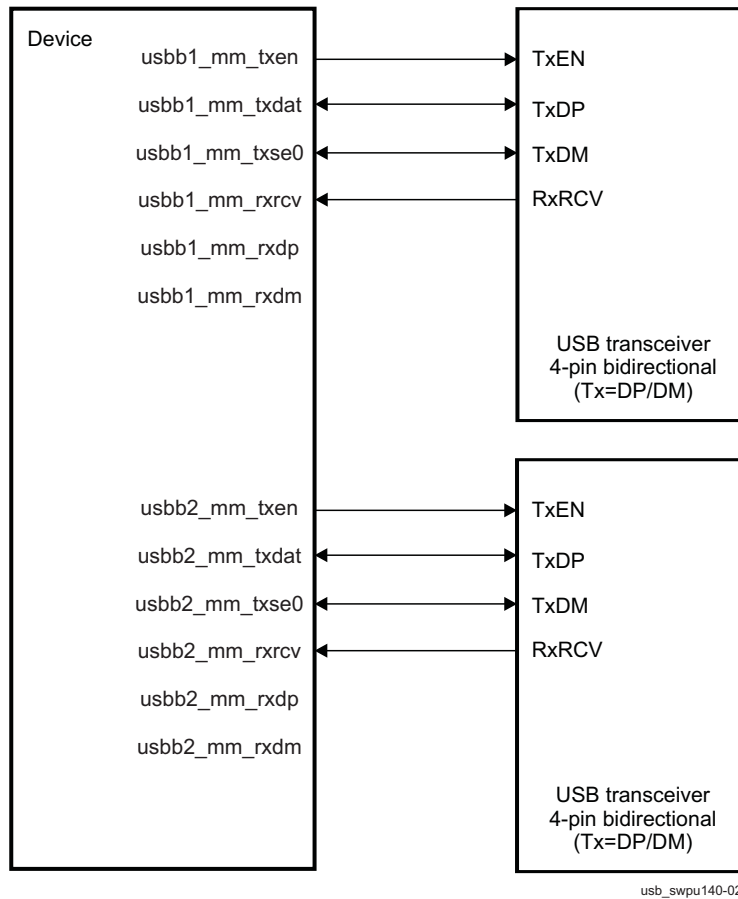

Figure 23-242 shows a USB port using DAT/SE0 encoding.

**Figure 23-242. 3-Pin Bidirectional Using DAT/SE0 Signaling**

The signaling described in [Table 23-948](#) is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

[Figure 23-243](#) shows a USB port using DP/DM encoding.

**Figure 23-243. 4-Pin Bidirectional Using DP/DM Signaling**

**23.11.2.2.4 TLL Interface Configurations in Serial Modes**

The HS USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are FS or LS only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

**23.11.2.2.4.1 Unidirectional TLL Serial Modes**

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 23-244 shows an external device using DAT/SE0 encoding.

**Figure 23-244. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling**

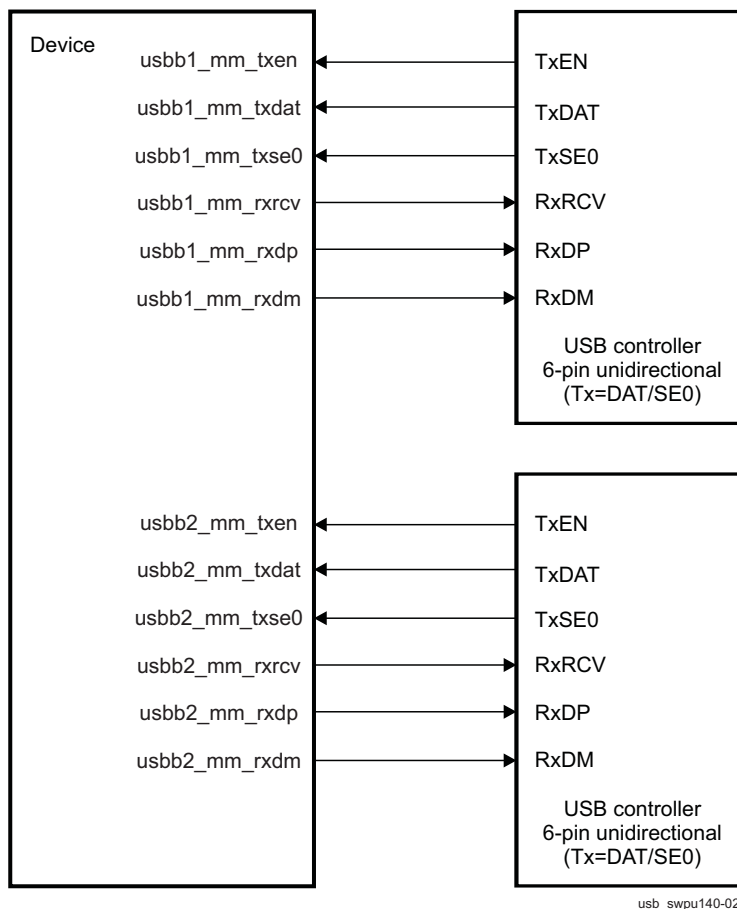

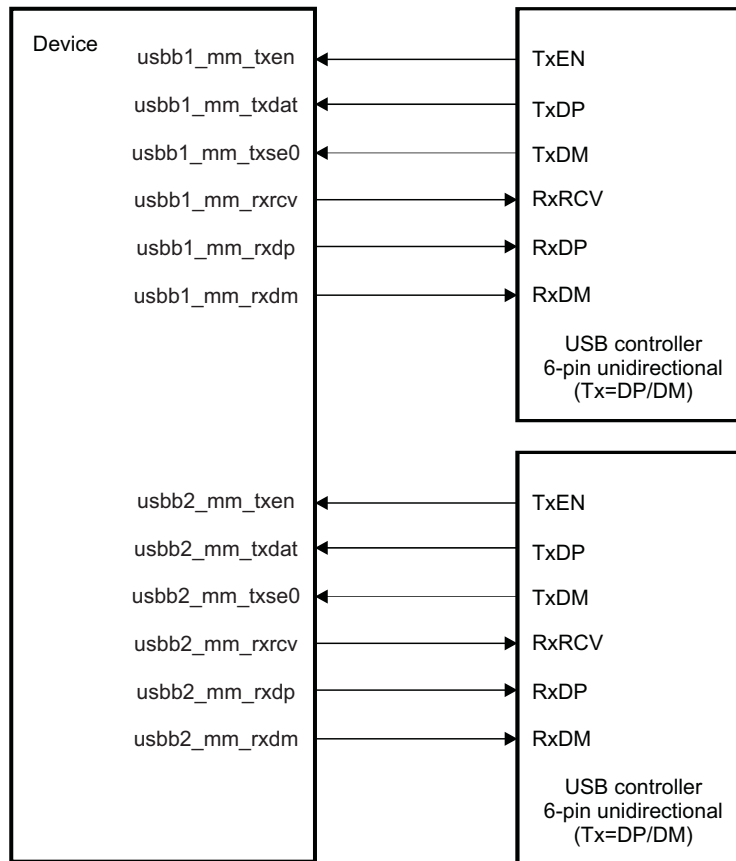

Figure 23-245 shows an external device using DP/DM encoding.

**Figure 23-245. 6-Pin Unidirectional TLL Using DP/DM Signaling**

usb\_swpu140-023

**23.11.2.2.4.2 Bidirectional TLL Serial Modes**

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations previously discussed. The same signals are mapped on the same physical pins, but in opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 23-246 shows an external device using DAT/SE0 encoding.

**Figure 23-246. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling**

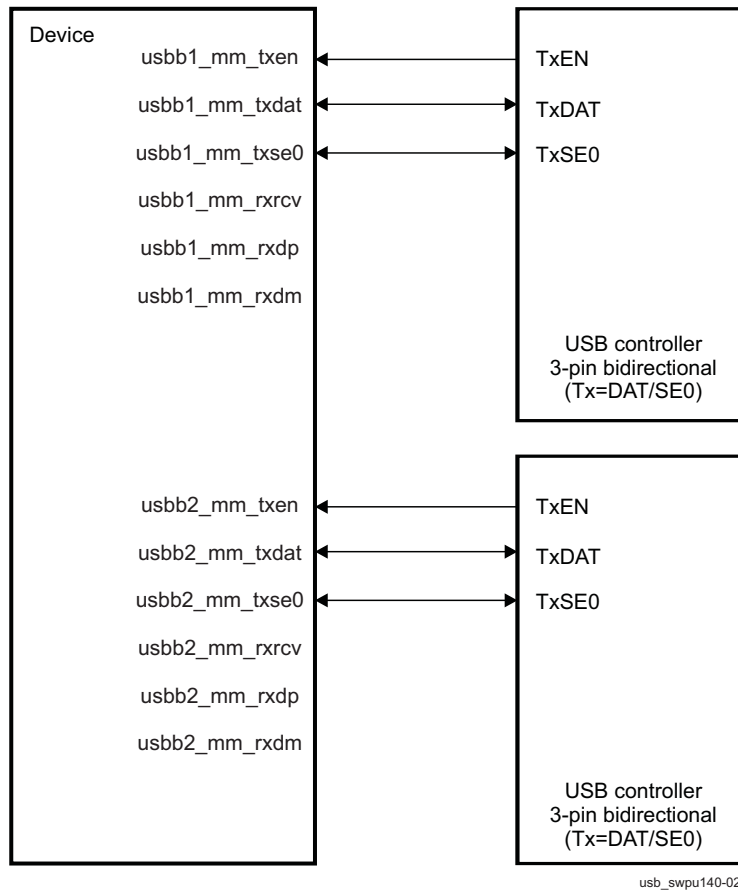

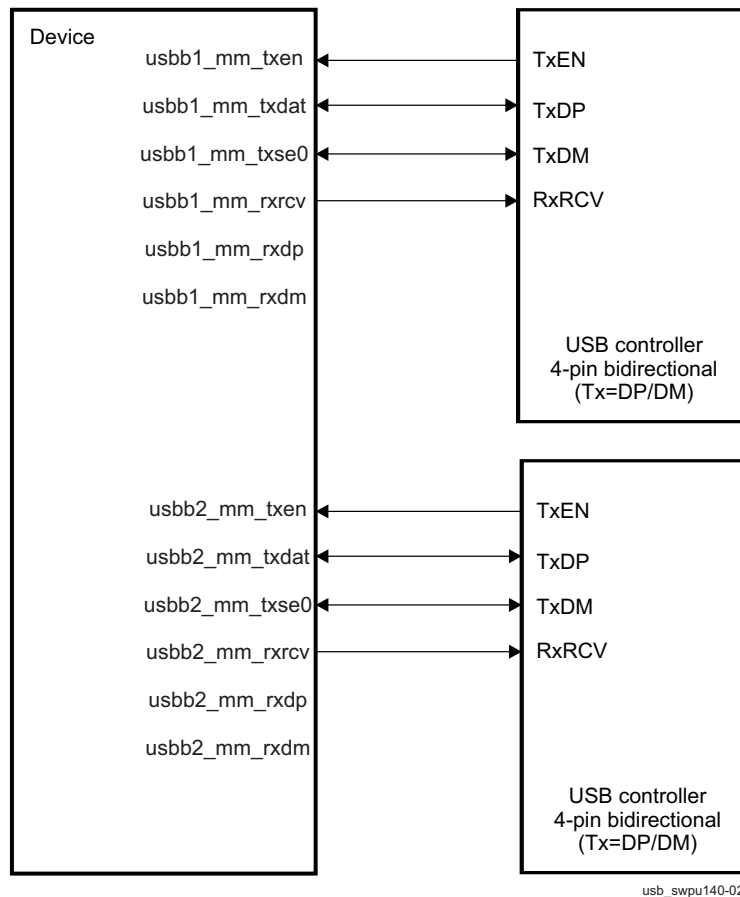

Figure 23-247 shows an external device using DP/DM encoding.

**Figure 23-247. 4-Pin Bidirectional TLL Using DP/DM Signaling**

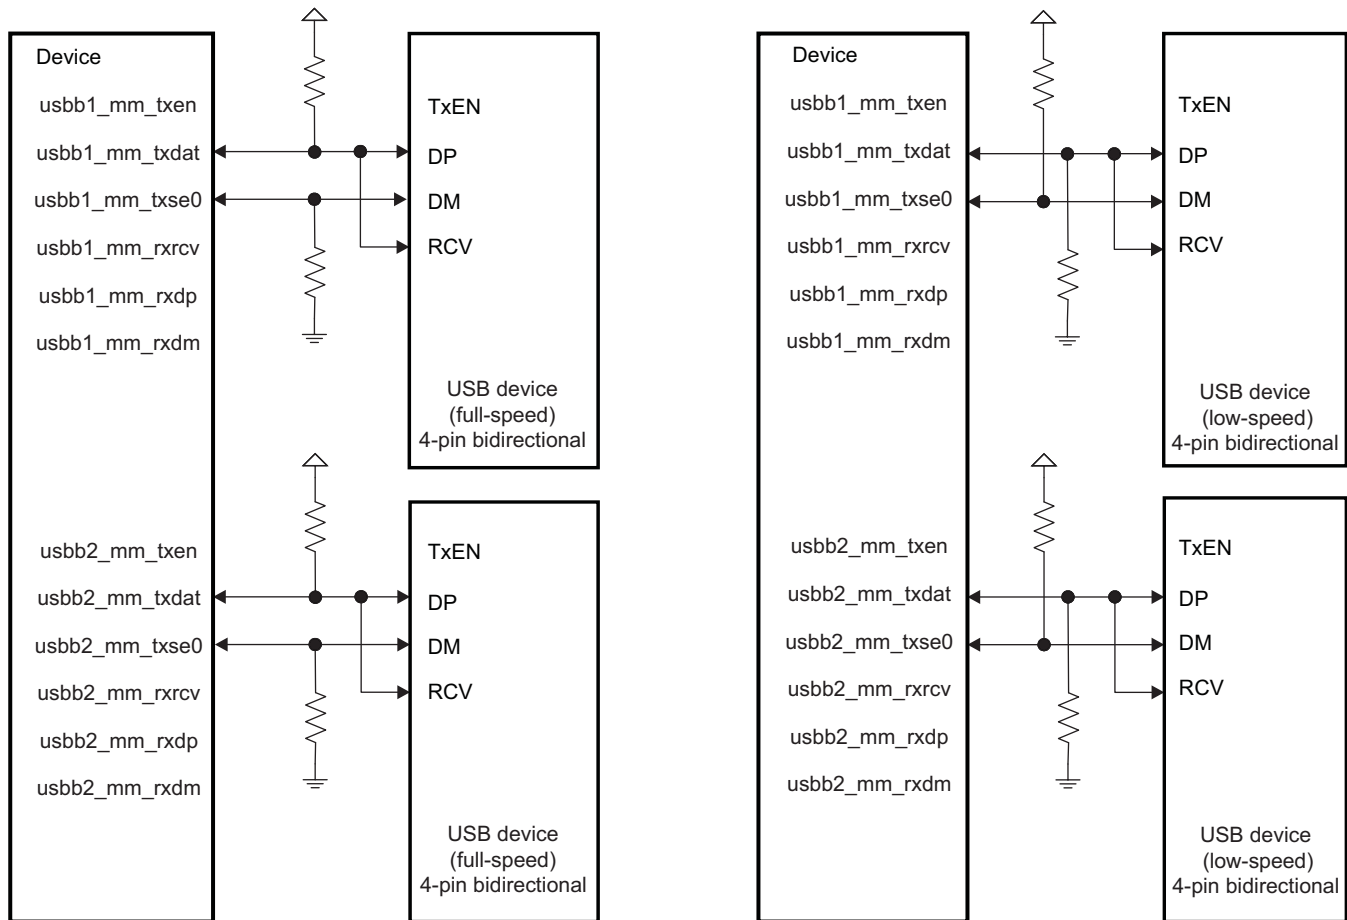

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described previously. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 23-248 shows a USB port using DP/DM encoding.

**Figure 23-248. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device**

usb\_swpu140-026

Table 23-949 shows the pullup/pulldown configuration for DP/DM encoding.

**Table 23-949. Pullup/Pulldown Configuration for DP/DM Encoding**

	<b>Nonconnected Device (Any Speed)</b>	<b>Connected LS Device</b>	<b>Connected FS Device</b>
DP	Pulldown	Pulldown	Pullup
DM	Pulldown	Pullup	Pulldown

Figure 23-249 shows a USB port using DAT/SE0 encoding.

**Figure 23-249. 2-Pin Bidirectional TLL Using DAT/SE0 Encoding, With 3-Pin Bidirectional USB Device**

usb\_swpu140-027

Table 23-950 shows the pullup/pulldown configuration for DAT/SE0 encoding.

**Table 23-950. Pullup/Pulldown Configuration for DAT/SE0 Encoding**

	Nonconnected Device (Any Speed)	Connected LS Device	Connected FS Device
DAT	Pulldown	Pulldown	Pullup
SE0	Pullup	Pulldown	Pulldown

### 23.11.2.2.5 Interface Description in Serial Modes

Table 23-951 describes the I/O of the HS USB host subsystem serial interfaces.

**Table 23-951. I/O Description**

Signal Name	I/O <sup>(1)</sup>	Description	Value at Reset
<b>Multiple-Mode FS/LS Serial Interface: Port 1</b>			
usbb1_mm_txse0	I/O	SE0 function in 3-pin bidirectional DAT/SE0 mode	0
	I/O	DM function in 4-pin bidirectional DP/DM mode	
	O	SE0 output in 6-pin unidirectional DAT/SE0 mode	
	O	DM output in 6-pin unidirectional DP/DM mode

	I/O	DP-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	DAT-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DP-TLL input in 6-pin unidirectional DP/DM TLL mode	
usbb1_mm_txen	O	Transmit enable in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 6-pin unidirectional modes	1
	I	Transmit enable in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 2-pin bidirectional TLL modes)	
usbb1_mm_rxcv	I	Differential receiver signal input in 4-pin bidirectional DP/DM or 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 mode)	Unknown
	O	Differential receiver signal output in 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 2-pin bidirectional TLL modes)	
usbb1_mm_rxdp	I	Single-ended DP receiver signal input in 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM modes)	Unknown
	O	Single-ended DP receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	
usbb1_mm_rxdm	I	Single-ended DM receiver signal input in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 2-pin bidirectional TLL modes)	Unknown
	O	Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	
<b>Multiple-Mode FS/LS Serial Interface: Port 2</b>			
usbb2_mm_txse0	I/O	SE0 function in 3-pin bidirectional DAT/SE0 mode	0
	I/O	DM function in 4-pin bidirectional DP/DM mode	
	O	SE0 output in 6-pin unidirectional DAT/SE0 mode	
	O	DM output in 6-pin unidirectional DP/DM mode	
	I/O	SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	SE0-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DM-TLL input in 6-pin unidirectional DP/DM TLL mode	
usbb2_mm_txdat	I/O	DAT function in 3-pin bidirectional DAT/SE0 mode	Unknown
	I/O	DP function in 4-pin bidirectional DP/DM mode	
	O	DAT output in 6-pin unidirectional DAT/SE0 mode	
	O	DP output in 6-pin unidirectional DAT/SE0 mode	

<sup>(1)</sup> I = Input; O = Output

**Table 23-951. I/O Description (continued)**

Signal Name	I/O <sup>(1)</sup>	Description	Value at Reset
<b>Multiple-Mode FS/LS Serial Interface: Port 1</b>			
	I/O	DAT-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode	
	I/O	DP-TLL in 2-/4-pin bidirectional DP/DM TLL mode	
	I	DAT-TLL input in 6-pin unidirectional DAT/SE0 TLL mode	
	I	DP-TLL input in 6-pin unidirectional DP/DM TLL mode	
usbb2_mm_txen	O	Transmit enable in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 6-pin unidirectional modes	1
	I	Transmit enable in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 2-pin bidirectional TLL modes)	
usbb2_mm_rxcv	I	Differential receiver signal input in 4-pin bidirectional DP/DM or 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 mode)	Unknown
	O	Differential receiver signal output in the 4-pin bidirectional DP/DM TLL or 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 2-pin bidirectional TLL modes)	
usbb2_mm_rxdp	I	Single-ended DP receiver signal input in 6-pin unidirectional modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM modes)	Unknown
	O	Single-ended DP receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	
usbb2_mm_rxdm	I	Single-ended DM receiver signal input in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 or 4-pin bidirectional DP/DM or 2-pin bidirectional TLL modes)	Unknown
	O	Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes)	

**NOTE:** ULPI (PHY) interfaces and ULPI TLL interfaces cannot be used together: either the ULPI (PHY) interfaces or the ULPI TLL interfaces are selected

**23.11.2.3 HSIC Interface**

The HS USB host subsystem supports the configurations with the HSIC interfaces shown in [Figure 23-250](#).

**Figure 23-250. HSIC Interface**

[Table 23-952](#) describes the I/O of the HSIC interface of the HS USB host subsystem.

**Table 23-952. HSIC Interface**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
<b>HSUSB HSIC1</b>			
usbb1_hsic_data	I/O	HS interchip data	Unknown

<sup>(1)</sup> I = Input; O = Output

**Table 23-952. HSIC Interface (continued)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
usbb1_hsic_strobe	I/O	HS interchip strobe	Unknown
<b>HSUSB HSIC2</b>

usbb2_hsic_strobe	I/O	HS interchip strobe	Unknown

### 23.11.3 HS Multiport USB Host Subsystem Integration

This section describes the integration of the HS USB host subsystem, including information about clocks, resets, and hardware requests.

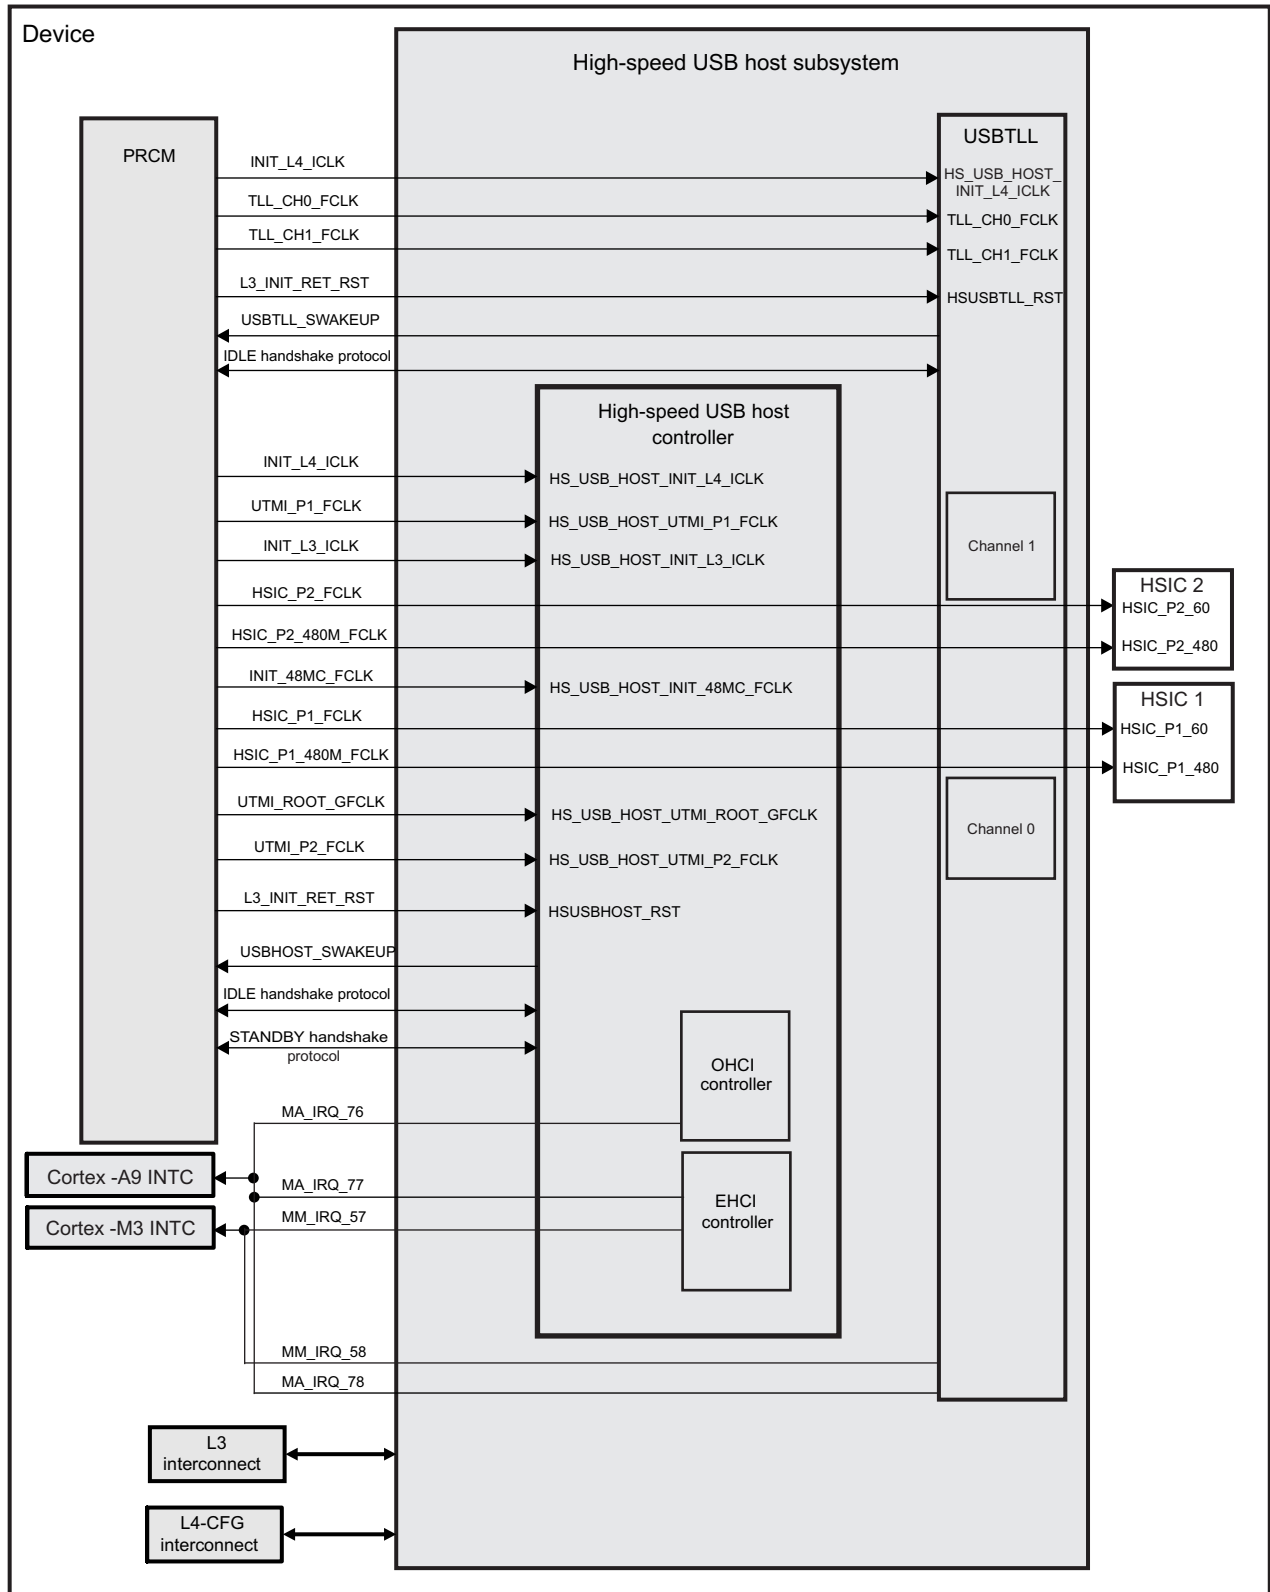

The USB host controller module includes other modules and additional logic attached to the UTMI/ULPI ports. The HS USB host controller is connected to the L3 interconnect master (initiator) and L4\_CFG interconnect slave (target) interfaces.

The elements of the USB HS host subsystem are:

- The multiport USB host controller. Each port uses one of the following modes:
  - ULPI, to a ULPI PHY (typically, off-chip)
  - UTMI, to a local UTMI (typically, on-chip) PHY or emulation of a PHY
- A local phase-locked loop (PLL), able to provide the USB-grade 48-, 60-, 480-MHz clocks
- Two TLL channels, bundled inside a USBTLL module. Each HS TLL channel can be seen as emulating a pair of back-to-back PHYs, and has:
  - A UTMI port, connected to a controller port (the host, in this case)
  - A ULPI port, connected to a (typically, off-chip) ULPI controller (peripheral, in this case)
- Two HSIC DFEs. The DFE plugs into the UTMI port of an HSIC-capable controller (the host, in this case), and controls HSIC-capable bidirectional I/O drivers driving the HSIC lines (strobe/data).

[Figure 23-251](#) shows the HS USB subsystem integration.

Figure 23-251. HS USB Subsystem Integration

usb-028

Table 23-953 through Table 23-955 summarize the integration of the module in the device.

**Table 23-953. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
HSUSBHOST	PD_L3_INIT	L3 L4_CFG
HSUSBTLL	PD_L3_INIT	

**Table 23-954. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSUSBHOST	HS_USB_HOST_INIT_L4_ICLK	INIT_L4_ICLK	PRCM	L4 interconnect enable signal for the slave interface on L4 (see , <i>CM Clock Source</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HS_USB_HOST_INIT_L3_ICLK	INIT_L3_ICLK	PRCM	L3 interconnect clock for the L3 master port interface (see , <i>CD_L3_INIT Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HSIC_P2_480	HSIC_P2_480M_FCLK	PRCM	480-MHz clock for the USB HSIC (see , <i>CD_L3_INIT Clock Domain</i> in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HS_USB_HOST_UTMI_P1_FCLK	UTMI_P1_FCLK/usbb1_ulpiiphy_clk	PRCM/external PHY IC	Port 1 UTMI interface functional clock (see , <i>CD_L3_INIT Clock Domain</i> , and , <i>CM1_USB Clock Generator</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HSIC_P1_60	HSIC_P1_FCLK	PRCM	60-MHz clock for the USB HSIC (see , <i>CD_L3_INIT Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HSIC_P1_480	HSIC_P1_480M_FCLK	PRCM	480-MHz clock for the USB HSIC (see , <i>CD_L3_INIT Clock Domain</i> in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HS_USB_HOST_INIT_48MC_FCLK	INIT_48MC_FCLK	PRCM	48-MHz functional clock for OHCI and EHCI (see , <i>CD_L3_INIT Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HSIC_P2_60	HSIC_P2_FCLK	PRCM	60-MHz clock for the USB HSIC (see , <i>CD_L3_INIT Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HS_USB_HOST_UTMI_ROOT_GFCLK	UTMI_ROOT_GFCLK	PRCM	60-MHz root hub clock (see , <i>CD_L3_INIT Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	HS_USB_HOST_UTMI_P2_FCLK	UTMI_P2_FCLK/usbb2_ulpiiphy_clk	PRCM/external PHY IC	Port 2 UTMI interface functional clock (see , <i>CD_L3_INIT Clock Domain</i> , and , <i>CM1_USB Clock Generator</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
HSUSBTLL	HS_USB_HOST_INIT_L4_ICLK	INIT_L4_ICLK	PRCM	L4 interconnect enable signal for the slave interface on L4 (see , <i>CM Clock Source</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	TLL_CH0_FCLK	TLL_CH0_FCLK	PRCM	Functional clock for channel 0 (see , <i>CD_L3_INIT Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
	TLL_CH1_FCLK	TLL_CH1_FCLK	PRCM	Functional clock for channel 1 (see , <i>CD_L3_INIT Clock Domain</i> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSUSBHOST	HSUSBHOST_RST	L3_INIT_RET_RST	PRCM	The signal resets the HSUSBHOST module.

**Table 23-954. Clocks and Resets (continued)**

HSUSBTLL	HSUSBTLL_RST	L3_INIT_RET_RST	PRCM	The signal resets the HSUSBTLL module.
----------	--------------	-----------------	------	--

**Table 23-955. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HSUSBHOST	HSUSB_EHCI_IRQ	MA_IRQ_77	Cortex-A9 INTC	Destination is Cortex-A9 interrupt controller (INTC).
	HSUSB_OHCI_IRQ	MA_IRQ_76	Cortex-A9 INTC	Destination is Cortex-A9 INTC.
	HSUSB_EHCI_IRQ	MM_IRQ_57	Cortex-M3 INTC	Destination is Cortex-M3 INTC.
HSUSBTLL	HSUSB_TLL_IRQ	MA_IRQ_78	Cortex-A9 INTC	Destination is Cortex-A9 INTC.
	HSUSB_TLL_IRQ	MM_IRQ_58	Cortex-M3 INTC	Destination is Cortex-M3 INTC.

The HS USB host controller and TLL module are attached to the L3\_INIT\_RET\_RST reset domain. The L3\_INIT\_RET\_RST signal resets the HS USB host controller and TLL module (see [Chapter 3, Power, Reset, and Clock Management](#)).

### 23.11.4 HS Multiport USB Host Subsystem Functional Description

This section describes the functionality of the HS USB host subsystem by describing the HS USB host controller, USBTLL module.

#### 23.11.4.1 USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following specifications:

- *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) Specification for USB Release 1.1*

[Figure 23-252](#) is an overview of the HS USB host controller internal architecture. It contains two independent, 3-port host controllers (OHCI and EHCI) that operate in parallel; however, only two physical ports are mapped in the device processor.

Figure 23-252. HS USB Host Controller Architecture

usb\_swpu140-029

### 23.11.4.1.1 HS USB Host Controller Software Reset

The HS USB host controller has its own software-reset function through the `UHH_SYSCONFIG[0]` `SOFTRESET` bit. Setting this bit to 0x1 resets the HS USB host controller. The bit value of 0x1 remains until the reset completes. When the software reset completes, the `SOFTRESET` bit is automatically set to 0x0 and has the same effect as the hardware reset.

### 23.11.4.1.2 HS USB Host Controller Power Management

The USB protocol defines power-saving modes, where clocks can be shut down. The host asynchronously detects ULPI/UTMI events and asserts the wake-up output, which causes the clocks to restart.

To reduce dynamic power consumption, an efficient idle scheme in the device is based on:

- Efficient local autoclock gating for each module
- Implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without complex software intervention. In both cases, the HS USB host controller power management is applied only to the interface clock domain.

The HS USB host controller has master (initiator) and slave (target) interfaces:

- As an initiator, the HS USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the HS USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

#### 23.11.4.1.2.1 Standby Handshake Protocol

The HS USB host controller can go into standby mode, in which case it stops generating transactions on the interconnect. To save power, the module standby leads the PRCM module to disable the USB clocks.

The HS USB host controller has an Mstandby/Mwait handshake mechanism with the PRCM module (see [Chapter 3, Power, Reset, and Clock Management](#)).

The module is ready to enter standby mode (indicated by the Mstandby signal to the PRCM module asserted) when there is no USB activity and the module is idle. It means:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go into standby mode based on the [UHH\\_SYSCONFIG\[5:4\] STANDBYMODE](#) bit field.

[Table 23-956](#) lists the settings of standby mode.

**Table 23-956. HS USB Host Controller Standby Mode Settings**

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The HS USB host controller enters standby mode unconditionally (Mstandby is asserted unconditionally).
0x1	No-standby	The HS USB host controller never enters standby mode (Mstandby is never asserted).
0x2	Smart-standby	The HS USB host controller is ready to enter standby mode (Mstandby is asserted) when there is no more activity on the USB master interface of the interconnect.

#### 23.11.4.1.2.2 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the HS USB host controller. The IDLE handshake protocol lets the PRCM module requiring the HS USB host controller to enter idle mode. Although this handshake is completely hardware and out of any software control, the way in which the HS USB host controller acknowledges the PRCM IDLE request is configurable through the [UHH\\_SYSCONFIG\[3:2\] SIDLEMODE](#) bit field. [Table 23-957](#) lists the settings of SIDLEMODE and the related acknowledgment modes.

**Table 23-957. HS USB Host Controller SIDLEMODE Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. Because such a mode does not prevent the loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The HS USB host controller never acknowledges any IDLE request from the PRCM module. This mode is safe from a module point of view because it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off, and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The HS USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.
0x3	Smart-idle + wakeup	The HS USB host controller enters smart mode with asynchronous (master) wakeup enabled.

### 23.11.4.1.2.3 Wake-Up Request

The wake-up request signal USBHOST\_SWAKEUP is generated by the HS USB host controller to the PRCM module.

### 23.11.4.1.3 HS USB Host Controller Save and Restore

The hardware context of the USB HS host can be frozen, saved, and restored.

The SAR mechanism extracts the hardware context of the HS USB host controller (after all USB activity is suspended) before switching off (saving), saves it to an external always-on memory, and reinjects it later after the module is switched on again and reset (restored) seamlessly for the USB. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

### 23.11.4.1.4 HS USB Host Controller Port Status

The USB port status is given through the [UHH\\_HOSTCONFIG\[8\] P1\\_CONNECT\\_STATUS](#) and [UHH\\_HOSTCONFIG\[9\] P2\\_CONNECT\\_STATUS](#) bits. The default value of these bits is 0x0 indicating that peripheral is disconnected.

### 23.11.4.1.5 HS USB Host Controller Burst Control

To avoid buffer underflow, bursts must be enabled by setting the [UHH\\_HOSTCONFIG\[4:2\]](#) bit field to 0x7, and the [UHH\\_HOSTCONFIG\[5\] ENA\\_INCR\\_ALIGN](#) bit to 1.

### 23.11.4.1.6 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the HS USB host controller, are described in the following list and are reflected in the register descriptions (see [Section 23.11.6.5, OHCI Registers](#)). For all standard features, see the *Open Host Controller Interface (OHCI) Specification for USB Release 1.0a*.

- [HCFMINTERVAL\[30:16\]](#) FSMPS bit field (FullSpeedMaxPacketSize) = 0x0000: The host stops scheduling new packets 0 bit times before the end of the frame (that is, by default, there is no scheduling overrun protection). To be updated by the software driver.
- [HCRHDESCRIPTORA\[7:0\]](#) NDP bit field (NumberDownstreamPorts) = 0x03 = three ports
- [HCRHDESCRIPTORA\[9\]](#) NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- [HCRHDESCRIPTORA\[8\]](#) PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally.
- [HCRHDESCRIPTORA\[31:24\]](#) POTPG bit field (PowerOnToPowerGood) = 0x0A = 10: Power ramp-up time is 10 x 2 ms = 20 ms.
- [HCRHDESCRIPTORB\[15:0\]](#) DR bit field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.

- **HCRHDESCRIPTORB**[31:16] PPCM bit field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

#### 23.11.4.1.7 UTMI Interface

The host controller supports two ports. Each host controller port is configured to be in UTMI or ULPI mode (see the **UHH\_HOSTCONFIG**[21:16] P<sub>x</sub>\_MODE bit field).

In UTMI mode, a port has its UTMI signal set broadcasting the outgoing packets (from the host to the peripherals) and gathering the incoming ones (from the addressed peripheral to the host). ULPI signals for that port are undefined/don't care on all ports.

The UTMI ports between the HS USB host controller and the USBTLL module are on-chip and remain invisible.

UTMI transparent mode is used to connect with the HSIC, (see the **UHH\_HOSTCONFIG**[17:16] P1\_MODE or **UHH\_HOSTCONFIG**[17:16] P2\_MODE bit fields).

#### 23.11.4.1.8 ULPI Interface

The host supports two ports. Each host controller port is configured to be either in UTMI or in ULPI mode (see the **UHH\_HOSTCONFIG**[17:16] P1\_MODE or **UHH\_HOSTCONFIG**[17:16] P2\_MODE bit fields).

In ULPI mode, a port has its ULPI signal set broadcasting the outgoing packets (that is, from the host to the peripherals) and gathering the incoming packets (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don't care on all ports.

---

**NOTE:** The ULPI clock (part of the 12-wire ULPI interface) is expected to be routed by the system from the ULPI CLK input I/O pad to the clock input used by all HS modes (ULPI and UTMI) for the current port.

---

### 23.11.4.2 USBTLL Module Functionality

#### 23.11.4.2.1 USBTLL Software Reset

Writing 0x1 to the **USBTLL\_SYSCONFIG**[1] SOFTRESET bit resets the USBTLL module. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFTRESET bit is automatically set to 0x0 and has the same effect as the hardware reset.

#### 23.11.4.2.2 USBTLL Power Management

The USB protocol defines power-saving modes, where clocks can be shut down.

##### 23.11.4.2.2.1 IDLE Handshake Protocol

The PRCM module handles an IDLE handshake protocol for the USBTLL module. The IDLE handshake protocol lets the PRCM module require the HS USBTLL module to enter idle mode.

The way in which the HS USBTLL module acknowledges the PRCM IDLE request is configurable through the **USBTLL\_SYSCONFIG**[4:3] SIDLEMODE bit field. [Table 23-958](#) lists related acknowledgment modes.

**Table 23-958. HS USBTLL Module SIDLEMODE Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The HS USB host controller acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations.
0x1	No-idle	The HS USB host controller never acknowledges any IDLE request from the PRCM module.
0x2	Smart-idle	The HS USB host controller acknowledges the IDLE request, basing its decision on its internal activity.

### 23.11.4.2.3 USBTLL Save and Restore

The SAR mechanism extracts the hardware context of the USBTLL module (after all USB activity is suspended) before switching off (saving), saves it to an external always-on memory, and reinjects it later after the module is switched on again and reset (restored) seamlessly for the USB.

Hardware context of the USBTLL module is accessed through the USBTLL\_SAR\_CNTX\_*i*[31:0] CNTX bit field.

The PRCM module enables the SAR mechanism for the USBTLL module. When set, the PRM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

For more information, see .

[Table 23-959](#) lists the USBTLL registers affected by the SAR context.

---

**NOTE:** Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

---

**Table 23-959. USBTLL Registers Affected by the SAR Context**

### 23.11.4.2.4 USBTLL Channels and Ports

Following the same convention as UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL, and not with respect to the link controller): An input goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module). Reciprocally, an output goes from the TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the HS USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other is the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the HS USB host controller in the device). There are two channels of the USBTLL module in the device.

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at the same time, depending on the configuration of the channel. The mode remains static throughout the USB operation.

### 23.11.4.2.5 USBTLL Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 23-960](#), lists the modes.

All configurations connect the PHY UTMI port (attached to the HS USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pad side).

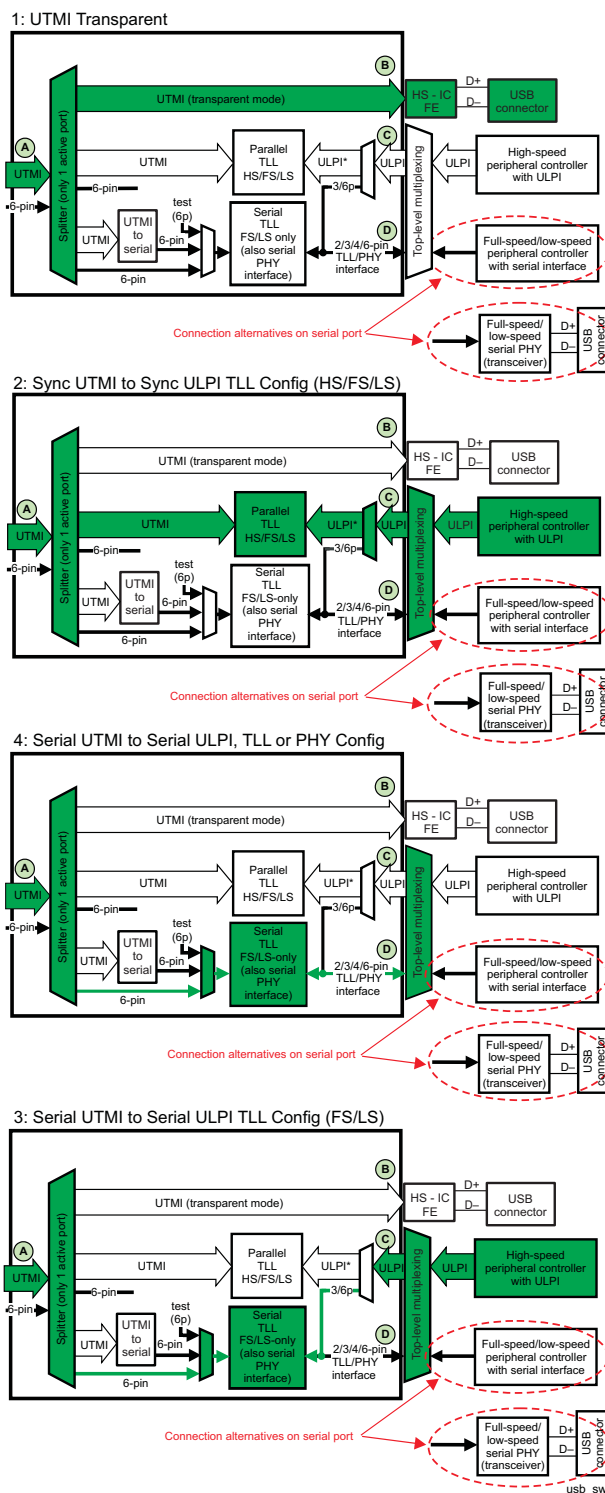

[Table 23-960](#) describes the available modes and the software settings required for each. Channel *i* has the following settings:

- CHANMODE: [TLL\\_CHANNEL\\_CONF\\_i\[2:1\]](#) CHANMODE bit field
- FLSMODE: [TLL\\_CHANNEL\\_CONF\\_i\[27:24\]](#) FLSMODE bit field
- FLSSEIRIALMODE\_3PIN/6PIN: Either the ULPI PHY-side [INTERFACE\\_CTRL\\_i\[1\]](#) FLSSEIRIALMODE\_3PIN bit or the [INTERFACE\\_CTRL\\_i\[0\]](#) FLSSEIRIALMODE\_6PIN bit (only one at a time can be set to 1)

**Table 23-960. USBTLL Channel Configuration**

Configuration	Mode	CHANMODE	FLSMODE	Other Settings	Ports	Speed	Remote Port Connection
1	UTMI transparent	0	N/A	–	A-B	–	UTMI transparent
2	ULPI synchronous TLL	0	N/A	FLSSEIRIALMODE_3PIN/6PIN = 0	A-C	HFL	ULPI link (peripheral controller)
3	Serial UTMI to serial ULPI TLL	0	N/A	FLSSEIRIALMODE_3PIN/6PIN = 1	A-C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode
4	Serial UTMI to serial TLL	1	0x4-0x7; 0xA-0xB	–	A-D	FL	Serial link (2-/3-/4-/6-pin)
4	Serial UTMI to serial PHY	1	0x0-0x3	–	A-D	FL	Serial transceiver (2-/3-/4-/6-pin)

Figure 23-253. Per-Configuration Data Path Through USBTLL

### 23.11.4.2.6 USBTLL VBUS Management and Emulations

In transceiver configurations, a USB cable is present, including a 5-V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power savings compared to a simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see [Figure 23-238](#) and [Figure 23-239](#) and the related explanations.

#### **23.11.4.2.6.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations**

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to and from the VBUS manager IC (typically, the transceiver).

Only serial transceiver configurations are concerned in the case of the HS USB host subsystem in the device.

##### **23.11.4.2.6.1.1 VBUS Management in Serial Transceiver Configurations**

VBUS management is not standardized in transceiver configurations. The chosen implementation is described in the following list (also see [Figure 23-238](#)).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup "charge," VBUS pulldown "discharge") is assumed to be handled separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver, especially in OTG cases).
- The status of VBUS must be sampled by the appropriate hardware (again, most often the transceiver) and reported by software to the USBTLL module, using the [TLL\\_CHANNEL\\_CONF\\_i\[16\]](#) DRVVBUS and [TLL\\_CHANNEL\\_CONF\\_i\[15\]](#) CHRGVBUS bits, as indicated in [Table 23-961](#).

[Table 23-961](#) lists the values to write to the [TLL\\_CHANNEL\\_CONF\\_i](#) register depending on the status of VBUS observed by the transceiver on the VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations, the signification of the fields is:

- DRVVBUS: Set to 1 to report a VBUS level greater than VBUS valid.
- CHRGVBUS: Set to 1 to report a VBUS level greater than session valid.

**Table 23-961. VBUS Level Software Reporting for Serial Transceiver Configuration**

VBUS Status	<a href="#">TLL_CHANNEL_CONF_i[16]</a> DRVVBUS	<a href="#">TLL_CHANNEL_CONF_i[15]</a> CHRGVBUS
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

##### **23.11.4.2.6.2 VBUS Emulation for TLL Configurations**

The TLL VBUS emulation sums up all actions on the VBUS line and obtains a voltage level, which is reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas an actual VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.
- The charge feature is used for VBUS-pulsing SRP and is enabled long enough to go over the session valid threshold, but without reaching VBUS valid. In the TLL, the transition to session valid is immediate, and VBUS valid is never reached even if the charge is intentionally kept active.
- The discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS toward the session-end level. For TLL, therefore, this is useless (although the UTMI input/ULPI register bit does exist, for compatibility), and is always don't care.

### 23.11.4.2.6.2.1 VBUS Emulation in ULPI TLL Modes

Table 23-962 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

**Table 23-962. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode**

VBUS Controls (Actions)			VBUS Level	VBUS Status		
OTG_CTRL_i[5] DRVVBUS	OTG_CTRL_i[4] CHRGVBUS	OTG_CTRL_i[3] DISCHRGVBUS		USB_INT_STA TUS_i[1] VBUSVALID bit	USB_INT_STATU S_i[2] SESSVALID bit	USB_INT_STATU S_i[3] SESSEND bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

### 23.11.4.2.6.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad hoc sideband signals (see Figure 23-239).

VBUS control can be done in software by writing to the following fields of the `TLL_CHANNEL_CONF_i` register:

- DRVVBUS: Set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: Set to 1 to pull up VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session-end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (The DRVVBUS bit and input signal are ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at the top level, a software alternative is to use the voltage status reported on the interface (through the standard UTMI+ sideband signals) of the local controller (the HS USB host controller in the device) and to pass it to the remote controller (a peripheral controller) by means of an ad hoc software-controller interface other than the USB. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

### 23.11.4.2.7 USBTLL Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the `TLL_CHANNEL_CONF_i[27:24]` FLSMODE bit field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are FS/LS only (that is, HS is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, RXDP, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output-enable signal associated with it on the USBTLL entity.

Table 23-963 lists the function of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

**Table 23-963. Serial Mode Description, Signal Functionality**

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode

TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDP	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDP	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

<sup>(1)</sup> RXRCV and RXDP carry the same information: RXDP can drive both inputs of the remote controller, and RXRCV can be kept unused.

<sup>(2)</sup> Same remark for TXDAT (for outputs) and RXRCV: TXDAT only is enough.

### 23.11.4.2.8 USBTLL Attach/Connect Emulation for Serial Modes

This section applies to all serial TLL modes in the following circumstances:

- In UTMI-to-serial mode ([TLL\\_CHANNEL\\_CONF\\_i](#)[2:1] CHANMODE = 0x1) for all TLL values of the [TLL\\_CHANNEL\\_CONF\\_i](#)[27:24] FLSMODE bit field (0x4–0x7; 0xA–0xB)
- In UTMI-to-ULPI TLL mode ([TLL\\_CHANNEL\\_CONF\\_i](#)[2:1] CHANMODE = 0x0) when the ULPI bus is switched to 6-pin or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one is implemented:

- The [TLL\\_CHANNEL\\_CONF\\_i](#)[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable:
  - When this bit is cleared, the local controller RX path shows only the local controller (the HS USB host controller) actions on the bus: TX driving, pullups, pulldowns. The same applies for the remote controller RX path (except that test override is not available).
  - When the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- The [TLL\\_CHANNEL\\_CONF\\_i](#)[5] TLLCONNECT bit emulates the USB electrical connect (that is, the pullup by the USB peripheral of one of the two USB lines [by a 1.5-k $\Omega$  resistor]), which causes the line state to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal; the connect control can be software (L4\_CFG interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit.
- The [TLL\\_CHANNEL\\_CONF\\_i](#)[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as previously defined) results in the pulling up of D+ (1 = full speed) or D– (0 = low speed) (see [Table 23-964](#)).
- The 15-k $\Omega$  pulldowns are implicit: Because they are supposed to be turned on at least on the host side of the bus, they do not require additional control.

---

**NOTE:** Sideband control and status actions such as pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require custom additions.

---

**Table 23-964. Pullup Enable Emulation in Serial TLL Modes**

TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D– Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	On	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

### 23.11.5 HS Multiport USB Host Subsystem Low-Level Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the HS USB host subsystem.

#### 23.11.5.1 Global Initialization

##### 23.11.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the HS USB host subsystem is used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the HS USB host subsystem.

[Table 23-965](#) describes the global initialization of surrounding modules.

**Table 23-965. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	All required clocks must be enabled. For ULPI PHY mode, mux the UTMI_P1_FCLK or UTMI_P2_FCLK to come from the external pad. See <a href="#">Section 3.6.3.2, CM Clock Source</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Cortex-A9 MPU INTC or Cortex-M3 MPU INTC	The Cortex-A9 MPU or Cortex-M3 MPU INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the HS multiport USB host subsystem. See the respective functional description in <a href="#">Chapter 17, Interrupt Controller</a> , for the MPUs.
Interconnect (L3 and L4)	For more information, see <a href="#">Section 13.2, L3 Interconnect</a> , and <a href="#">Section 13.3, L4 Interconnect</a> .

##### 23.11.5.1.2 HS Multiport USB Host Subsystem Global Initialization

This procedure in [Table 23-966](#) initializes the HS multiport USB host subsystem after a power-on or software reset.

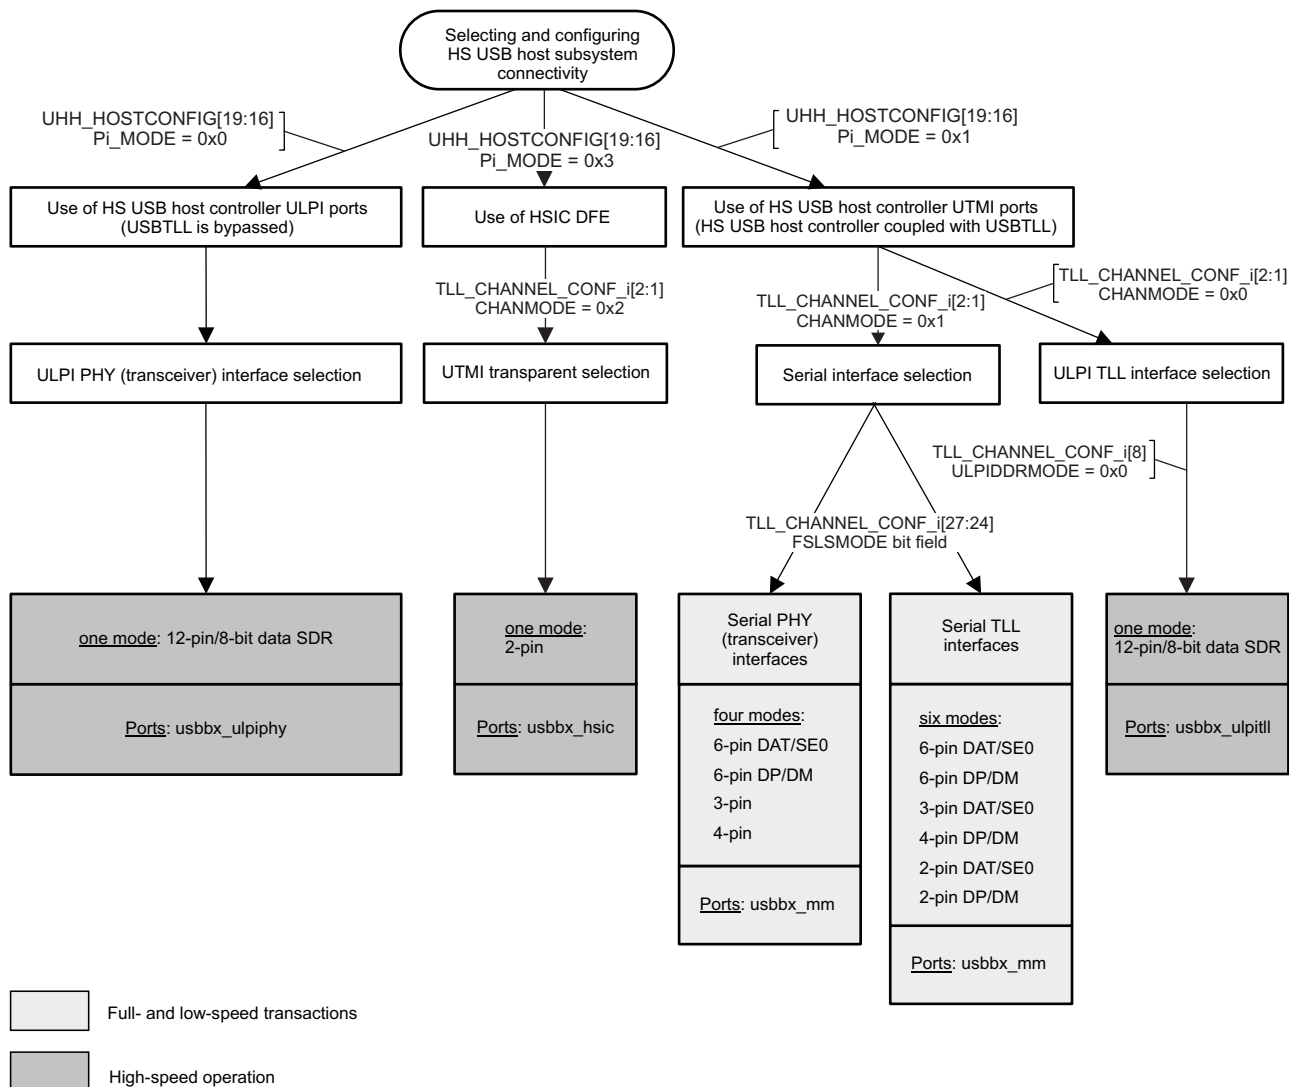

**Table 23-966. HS Multiport USB Host Subsystem Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset on the TLL module.	<a href="#">USBTLL_SYSCONFIG[1]</a> SOFTRESET	0x1
Wait until reset is finished.	<a href="#">USBTLL_SYSSTATUS[0]</a> RESETDONE	=0x1
Enable IRQ event for the TLL module.	<a href="#">USBTLL_IRQENABLE[1]</a> FCLK_END_EN	0x1
Enable IRQ event for the TLL module.	<a href="#">USBTLL_IRQENABLE[0]</a> FCLK_START_EN	=0x1
Perform a software reset on the HS USB controller.	<a href="#">UHH_SYSCONFIG[0]</a> SOFTRESET	0x1
Wait until the EHCI HS host is out of reset.	<a href="#">UHH_SYSSTATUS[2]</a> EHCI_RESETDONE	=0x1
Wait until the OHCI HS host is out of reset.	<a href="#">UHH_SYSSTATUS[1]</a> OHCI_RESETDONE	=0x1
Enable IRQ event for the OHCI HS host.	<a href="#">HCINTERRUPTENABLE[31]</a> MIE	0x1
Enable IRQ event for the EHCI HS host.	<a href="#">USBINTR[0]</a> USBIE	0x1

### 23.11.5.2 Operational Modes Configuration (Selecting and Configuring USB Connectivity)

Figure 23-254 shows how to select and configure the HS USB host subsystem connectivity.

Figure 23-254. Selecting and Configuring HS USB Host Subsystem Connectivity

usb\_swpu140-034

Table 23-967. Register Call Summary for Selecting and Configuring High-Speed USB Host Subsystem Connectivity

Register Name	
<code>UHH_HOSTCONFIG</code>	<code>TLL_CHANNEL_CONF_i</code>

### 23.11.5.3 USBTLL Registers

The USBTLL module contains two types of software-programmable registers: TLL control and status registers and ULPI PHY-side registers.

#### 23.11.5.3.1 TLL Control and Status Registers

These 32-bit registers configure the various channels. These registers are accessed by the MPU through the L4\_CFG interconnect. They are used primarily before USB activity starts. The registers are:

- OCP-standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

### **23.11.5.3.2 ULPI PHY-Side Registers**

Each TLL channel emulates a ULPI transceiver and therefore contains this set of 8-bit PHY-side registers, per ULPI specification. The registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in the ULPI specification

These registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

They are accessible by the L4\_CFG interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4\_CFG interconnect address space, where they can be accessed through byte accesses. If a conflict occurs between the two access modes, access over ULPI has priority, but both accesses eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4\_CFG interconnect accesses can compromise proper USB operation. The L4\_CFG interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. When the module is switched on again, the ULPI register contents, which have been lost, can be restored over the L4\_CFG interconnect before USB operations restart, provided they were saved elsewhere beforehand.

### 23.11.6 HS USB Host Subsystem Register Manual

This section provides the register description of the module.

#### 23.11.6.1 USB\_Host\_HS Instance Summary

Table 23-968 summarizes the USB\_Host\_HS instance.

**Table 23-968. USB\_Host\_HS Instance Summary**

Module Name	L4_CFG Base Address	Size
USBTLLHS_config	0x4A06 2000	2KB
USBTLLHS_ULPI	0x4A06 2800	2KB
HSUSBHOST	0x4A06 4000	2KB
OHCI	0x4A06 4800	1KB
EHCI	0x4A06 4C00	1KB

#### 23.11.6.2 USBTLLHS\_config Registers

##### 23.11.6.2.1 USBTLLHS\_config Register Summary

Table 23-969 summarizes the USBTLLHS\_config register mapping.

**Table 23-969. USBTLLHS\_config Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address
<a href="#">USBTLL_REVISION</a>	R	32	0x0000 0000	0x4A06 2000
<a href="#">USBTLL_HWINFO</a>	R	32	0x0000 0004	0x4A06 2004
<a href="#">USBTLL_SYSCONFIG</a>	RW	32	0x0000 0010	0x4A06 2010
<a href="#">USBTLL_SYSSTATUS</a>	R	32	0x0000 0014	0x4A06 2014
<a href="#">USBTLL_IRQSTATUS</a>	RW	32	0x0000 0018	0x4A06 2018

8	RESERVED		R	0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode. Hardcoded, for legacy only.  Read 0x1: ULPI clock provided by PHY side (i.e. TLL, from functional clock). ULPI clock is output	R Rreturns 1s	1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: input m(N)_tlpuen, register field TIIConnect.  0x0: Connect is Low-speed: D- pullup  0x1: Connect is Full-Speed: D+ pullup	RW	1
5	TLLCONNECT	Emulation of Full/Low-Speed connect (that is, D+ resp D- pullup) for serial TLL modes. Speed is determined by field TIIISpeed.  0x0: Unconnected  0x1: Connected	RW	0
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL)  0x0: Cable detach emulated on serial TLL  0x1: Cable attach emulated on serial TLL	RW	1
3	UTMIISADEV	Select the cable end "seen" by UTMI side of TLL, i.e. the emulated USB cable's orientation. The host must always be on A-side, peripheral on B-side. Reset value depends on generic DEFUTMIISHOST.  0x0: UTMI side is peripheral, ULPI side is host  0x1: UTMI side is host, ULPI side is peripheral	RW	1
2:1	CHANMODE	Main channel mode selection  0x0: UTMI-to-ULPI TLL mode (HS capable): to ULPI controller  0x1: UTMI-to-serial (FS/LS) mode: to serial controller (TLL) or serial PHY  0x2: Transparent UTMI mode: to UTMI PHY  0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unlocked and kept under reset.  0x0: Channel i disabled  0x1: Channel i enabled	RW	0

INTERFACE_PROTECT_DISABLE	RESERVED		AUTORESUME	CLOCKSPENDM	RESERVED		FSLSSERIALMODE_3PIN	FSLSSERIALMODE_6PIN

Bits	Field Name	Description	Type	Reset
7	INTERFACE_PROTECT_DISABLE	Controls circuitry built into the PHY for protecting the ULPI interface when the link 3-states stp and data. Write 0x0: No effect on bit value Write 0x1: Clear the bit to 0.	RW	0x0
6:5	RESERVED	Reserved	R	0x0
4	AUTORESUME	Enables the PHY to automatically drive resume signaling. On by default. Write 0x0: No effect on bit value Write 0x1: Clear the bit to 0.	RW	0x0
3	CLOCKSPENDM	Active low clock suspend for serial modes (6-pin/3-pin). Write 0x0: No effect on bit value Write 0x1: Clear the bit to 0.	RW	0x0
2	RESERVED	Reserved	R	0x0
1	FSLSSERIALMODE_3PIN	Sets the ULPI interface to 3-pin (FS/LS only) serial mode. Autocleared when serial mode is exited. Write 0x0: No effect on bit value Write 0x1: Clear the bit to 0.	RW	0x0
0	FSLSSERIALMODE_6PIN	Sets the ULPI interface to 6-pin (FS/LS only) serial mode. Autocleared when serial mode is exited. Write 0x0: No effect on bit value Write 0x1: Clear the bit to 0.	RW	0x0

**CAUTION**

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

OHCI register descriptions conform to the OHCI USB standard: *Open Host Controller Interface Specification for USB, Release 1.0a*. For more information about these registers or for new specification releases, search OHCI on [www.usb.org](http://www.usb.org).

**23.11.6.5.2 OHCI Register Description**

Table 23-1085 through Table 23-1129 describe the OHCI registers.

**Table 23-1085. HCREVISION**

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved	R	0x0000
20	PRSC	Port 1 reset status change. This bit is set when the port 1 port reset status bit has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0
19	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
18	PSSC	Port 1 suspends status change. Set when the port leaves the suspend state; that is, after the full resume sequence has completed.  Write 0x0: No effect  Read 0x0: No resume completed (since either the last software clear, or the last port reset).  Read 0x1: Resume completed on the port  Write 0x1: Clears the bit	RW	0
17	PESC	Port 1 enable status change. This bit is set when the port 1 port enable status has changed.  Write 0x0: No effect Write 0x1: Clears this bit	RW	0
16	CSC	Port 1 connect status change. This bit is set when the port1 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set.  Write 0x0: No effect Write 0x1: Clears this bit <b>Note:</b> If the <a href="#">HCRHDESCRIPTORB[1]</a> DR bit is set, this bit is set only after a root hub reset to inform the system that the device is attached.	RW	0
15:10	RESERVED	Reserved	R	0x00
9	LSDA_CPP	Port 1 low-speed device attached/clear port power. This bit is valid only when port 1 current connect status is 1. Read 0x0: A full-speed device is attached to port 1. Read 0x1: A low-speed device is attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port power status	RW	0
8	PPS_SPP	Port 1 port power status/set port power Read 0x0: Port 1 power is enabled. Read 0x1: Port 1 power is not enabled. Write 0x0: No effect Write 0x1: Sets the port 1 port power status bit	RW	0
7:5	RESERVED	Reserved	R	0x0
4	PRS_SPR	Port 1 port reset status/set port reset Read 0x0: USB reset is not being sent to port 1. Read 0x1: Port 1 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 1 port reset status bit and causes the USB host controller to begin signaling USB reset to port 1	RW	0
3	RESERVED		R	0
2	PSS_SPS	Port 1 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence.  Write 0x0: No effect  Read 0x0: Port 1 is not in the USB suspend state. Read 0x1: Port 1 is in the USB suspend state or is in the resume sequence.  Write 0x1: If port 1 current connect status is 1, sets the port 1 port suspend status bit and places port 1 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port.	RW	0

Bits	Field Name	Description	Type	Reset
1	PES_SPE	Port 1 port enable status/set port enable. This bit is automatically set at completion of port 1 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 1 is not enabled. Read 0x1: Port 1 is enabled. Write 0x0: No effect Write 0x1: When port 1 current connect status is 1 sets the port 1 port enable status bit. When port 1 current status is 0 has no effect.	RW	0
0	CCS_CPE	Port 1 current connection status/clear port enable Read 0x0: No USB device is attached to port 1. Read 0x1: A USB device is currently attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port enable bit Note: This bit is set to 1 if the <a href="#">HCRHDESCRIPTORB</a> [1 DR bit] is set to indicate a nonremovable device on port 1.	RW	0

<b>Physical Address</b>	<a href="#">0x4A06 4858</a>		
<b>Description</b>	HC port 2 status and control register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								PRSC	RESERVED	PSSC	PESC	CSC	RESERVED				LSDA_CPP	PPS_SPP	RESERVED	PRS_SPP	RESERVED	PSS_SPS	PES_SPE	CCS_CPE							

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved	R	0x000
20	PRSC	Port 2 reset status change. This bit is set when the port 2 port reset status bit has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0
19	RESERVED		RW	0
18	PSSC	Port 2 suspend status change. Set when the port leaves the suspend state; that is, after the full resume sequence has completed. Write 0x0: No effect Read 0x0: No resume completed (since either the last software clear, or the last port reset). Read 0x1: Resume completed on the port. Write 0x1: Clears the bit	RW	0
17	PESC	Port 2 enable status change. This bit is set when the port 2 port enable status has changed. Write 0x0: No effect Write 0x1: Clears this bit	RW	0

Bits	Field Name	Description	Type	Reset
16	CSC	Port 2 connect status change. This bit is set when the port 2 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect Write 0x1: Clears this bit <b>Note:</b> If the <a href="#">HCRHDESCRIPTORB[1]</a> DR bit is set, this bit is set only after a root hub reset to inform the system that the device is attached.	RW	0
15:10	RESERVED	Reserved	R	0x00
9	LSDA_CPP	Port 2 low-speed device attached/clear port power. This bit is valid only when port 2 current connect status is 1. Read 0x0: A full-speed device is attached to port 2. Read 0x1: A low-speed device is attached to port 2. Write 0x0: No effect Write 0x1: Clears the port 2 port power status	RW	0
8	PPS_SPP	Port 2 port power status/set port power Read 0x0: Port 2 power is enabled. Read 0x1: Port 2 power is not enabled. Write 0x0: No effect Write 0x1: Sets the port 2 port power status bit	RW	0
7:5	RESERVED	Reserved	R	0x0
4	PRS_SPR	Port 2 port reset status/set port reset Read 0x0: USB reset is not being sent to port 2. Read 0x1: Port 2 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 2 port reset status bit and causes the USB host controller to begin signaling USB reset to port 2	RW	0
3	RESERVED		RW	0
2	PSS_SPS	Port 2 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect Read 0x0: Port 2 is not in the USB suspend state. Read 0x1: Port 2 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 2 current connect status is 1, sets the port 2 port suspend status bit and places port 2 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port.	RW	0
1	PES_SPE	Port 2 port enable status/set port enable. This bit is automatically set at completion of port 2 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 2 is not enabled. Read 0x1: Port 2 is enabled. Write 0x0: No effect Write 0x1: When port 2 current connect status is 1 sets the port 2 port enable status bit. When port 2 current status is 0 has no effect.	RW	0
0	CCS_CPE	Port 2 current connection status/clear port enable Read 0x0: No USB device is attached to port 2. Read 0x1: A USB device is currently attached to port 2. Write 0x0: No effect Write 0x1: Clears the port 2 port enable bit <b>Note:</b> This bit is set to 1 if the <a href="#">HCRHDESCRIPTORB[1]</a> DR bit is set to indicate a nonremovable device on port 2.	RW	0

<sup>(1)</sup> i = 0 to 2

#### CAUTION

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

EHCI register descriptions conform to the EHCI USB standard: *Enhanced Host Controller Interface (EHCI) Specification for USB, Release 1.1*. For more information about these registers or for new specification releases, search EHCI on [www.usb.org](http://www.usb.org).

#### 23.11.6.6.2 EHCI Register Description

Table 23-1132 through Table 23-1174 describe the EHCI registers.

**Table 23-1132. HCCAPBASE**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	EHCI
<b>Physical Address</b>	0x4A06 4C00		
<b>Description</b>	Host controller capability register		
<b>Type</b>	R

HCVERSION								RESERVED								CAPLENGTH															

Bits	Field Name	Description	Type	Reset
31:16	HCVERSION	Interface version number. It contains a BCD encoding of the EHCI revision number supported by this host controller.  [7:4] Major revision [3:0] Minor revision	R	0x0100
15:8	RESERVED	Reserved	R	0x00
7:0	CAPLENGTH	Capability register length	R	0x10

**Table 23-1133. Register Call Summary for Register HCCAPBASE**

High-Speed Multiport USB Host Subsystem

- [EHCI Register Summary: \[0\]](#)

**Table 23-1134. HCSPARAMS**

<b>Address Offset</b>	0x0000 0004	<b>Instance</b>	EHCI
<b>Physical Address</b>	0x4A06 4C04		
<b>Description</b>	Host controller structural parameters		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								RESERVED	P_INDICATOR	N_CC		N_PCC		PRR	RESERVED	PPC	N_PORTS														

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Reserved	R	0x000
19:17	RESERVED	Reserved	R	0x0
16	P_INDICATOR	Port indicator support indication  This bit indicates whether the ports support port indicator control.  0x1: The port status and control registers include a read/write field for controlling the state of the port indicator.	R	0
15:12	N_CC	Number of companion controllers  This field indicates the number of companion controllers associated with this USB 2.0 host controller.  0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports.	R	0x1

Bits	Field Name	Description	Type	Reset
		Others: There are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports.		
11:8	N_PCC	Number of ports per companion controller  This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software.  For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3.  The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc.  The number in this field must be consistent with N_PORTS and N_CC.	R	0x3
7	PRR	Port routing rules  The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on.	R	0
6:5	RESERVED	Reserved	R	0x0
4	PPC	Port power control  This field indicates whether the host controller implementation includes port power control.  0x0: The ports do not have port power switches.  0x1: The ports have port power switches.	R	1
3:0	N_PORTS	Number of downstream ports  This field specifies the number of physical downstream ports implemented on this host controller.	R	0x3

Bits	Field Name	Description	Type	Reset
31:18	RESERVED	Reserved	R	0x0000
17	LPM	Link power management capability  0: Link power management not supported  1: Link power management supported	R	1
16	RESERVED	Reserved	R	0

Bits	Field Name	Description	Type	Reset
15:8	EECP	EHCI extended capabilities pointer  This field indicates the existence of a capabilities list. 0x0: No extended capabilities are implemented. Others: The offset in PCI configuration space of the first EHCI extended capability.	R	0x00
7:4	IST	Isochronous scheduling threshold  This field indicates where software can reliably update the isochronous schedule in relation to the current position of the executing host controller.  The host controller can hold one microframe of isochronous data structures before flushing the state.	R	0x1
3	RESERVED	Reserved	R	0
2	ASPC	Asynchronous schedule park capability  0x1: The host controller supports the park feature for high-speed queue heads in the asynchronous schedule.  The feature can be disabled or enabled and set to a specific level by using the USBHOST.USBCMD[11]ASPME bit and the USBHOST.USBCMD[9:8] ASPMC bit field.	R	1
1	PFLF	Programmable frame list flag  0x0: System software must use a frame list length of 1024 elements with this host controller.  0x1: System software can specify and use a smaller frame list and configure the host controller through the USBHOST.USBCMD[3:2] FLS bit field. The frame list must always be aligned on a 4-K page boundary.	R	1
0	BIT64AC	64-bit addressing capability  This field documents the addressing range capability of this implementation.  0x0: Data structures using 32-bit address memory pointers  0x1: Data structures using 64-bit address memory pointers	R	0

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved	R	0x0
27:24	HIRD	Host-initiated resume duration. If LPM is enabled, this field is RW; otherwise, it is R. The minimum for K-state during resume from LPM: 0x0: 50 $\mu$ s Each increment adds 75 $\mu$ s.	RW	0x0
23:16	ITC	Interrupt threshold control  This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined.  0x00: Reserved 0x01: 1 microframe 0x02: 2 microframes 0x04: 4 microframes 0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined	RW	0x08
15:12	RESERVED	Reserved	R	0x0
11	ASPME	Asynchronous schedule park mode enable  0x0: Park mode is disabled. 0x1: Park mode is enabled.	RW	1
10	RESERVED	Reserved	R	0
9:8	ASPMC	Asynchronous schedule park mode count  It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule.  Valid values are 0x1 to 0x3. Software must not write 0 to this bit when park mode enable is 1 because this may result in undefined behavior.	RW	0x3
7	LHCR	Light host controller reset  It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers.  Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. Read 0x1: Light host controller reset is still ongoing.	RW	0
6	IAAD	Interrupt on async advance doorbell  This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule.  Write 0x1: Ring the doorbell.  Software must not write 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results.	RW	0
5	ASE	Asynchronous schedule enable  This bit controls whether the host controller skips processing the asynchronous schedule.  0x0: Do not process the asynchronous schedule	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: Use the USBHOST.ASYNCLISTADDR register to access the asynchronous schedule.		
4	PSE	Periodic schedule enable  This bit controls whether the host controller skips processing the periodic schedule.  0x0: Do not process the periodic schedule 0x1: Use the USBHOST.PERIODICLISTBASE register to access the periodic schedule.	RW	0
3:2	FLS	Frame list size  This field specifies the size of the frame list. The size of the frame list controls which bits in the frame index register should be used for the frame list current index.  0x0: 1024 elements (4096 bytes) 0x1: 512 elements (2048 bytes) 0x2: 256 elements (1024 bytes), for resource-constrained environments 0x3: Reserved	RW	0
1	HCR	Host controller reset  This control bit is used by software to reset the host controller. Write  0x1: Reset the host controller, the PCI configuration registers are not affected by this reset and all operational registers are set to their initial values.  This bit is set to 0 by the host controller when the reset process is complete.	W	0
0	RS	Run/stop  0x1: Run, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1.  0x0: Stop, the host controller completes the current and any actively pipelined transactions on the USB and then halts.	RW	0

<b>Bits</b>	31:16																15																															
<b>Field Name</b>	RESERVED																ASS																															
<b>Description</b>	Reserved																Asynchronous schedule status  The bit reports the current real status of the asynchronous schedule.																															
<b>Type</b>	R																R																															
<b>Reset</b>	0x0000																0																															

Bits	Field Name	Description	Type	Reset
		0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled.		
14	PSS	Periodic schedule status  The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled.	R	0
13	REC	Reclamation  It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host controller halted  This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00
5	IAA	Interrupt on async advance  System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by setting the USBHOST.USBCMD[6] IAAD bit to 1. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host system error  The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.	RW	0
3	FLR	Frame list rollover  The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port change detect  The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_ <i>[13]</i> PO bit is set to 0 has a change bit transition from 0 to 1 or a USBHOST.PORTSC_ <i>[6]</i> FPR bit transition from 0 to 1.  This bit is also set as a result of the USBHOST.PORTSC_ <i>[1]</i> CSC bit being set to 1 after system software has relinquished ownership of a connected port by setting the USBHOST.PORTSC_ <i>[13]</i> PO bit to 1.	RW	0
1	USBEI	USB error interrupt  The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB interrupt  The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set.  The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).	RW	0

## 23.12 High-Speed USB OTG Controller

This section describes the high-speed USB On-The-Go (OTG) controller of the device.

---

**NOTE:** The high-speed USB OTG controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

This document contains materials that are ©2003-2007 Mentor Graphics Corporation.

---

### 23.12.1 High-Speed USB OTG Controller Overview

The High-Speed USB controller is a high-speed, USB OTG dual-role-device (DRD) link controller supporting the following modes:

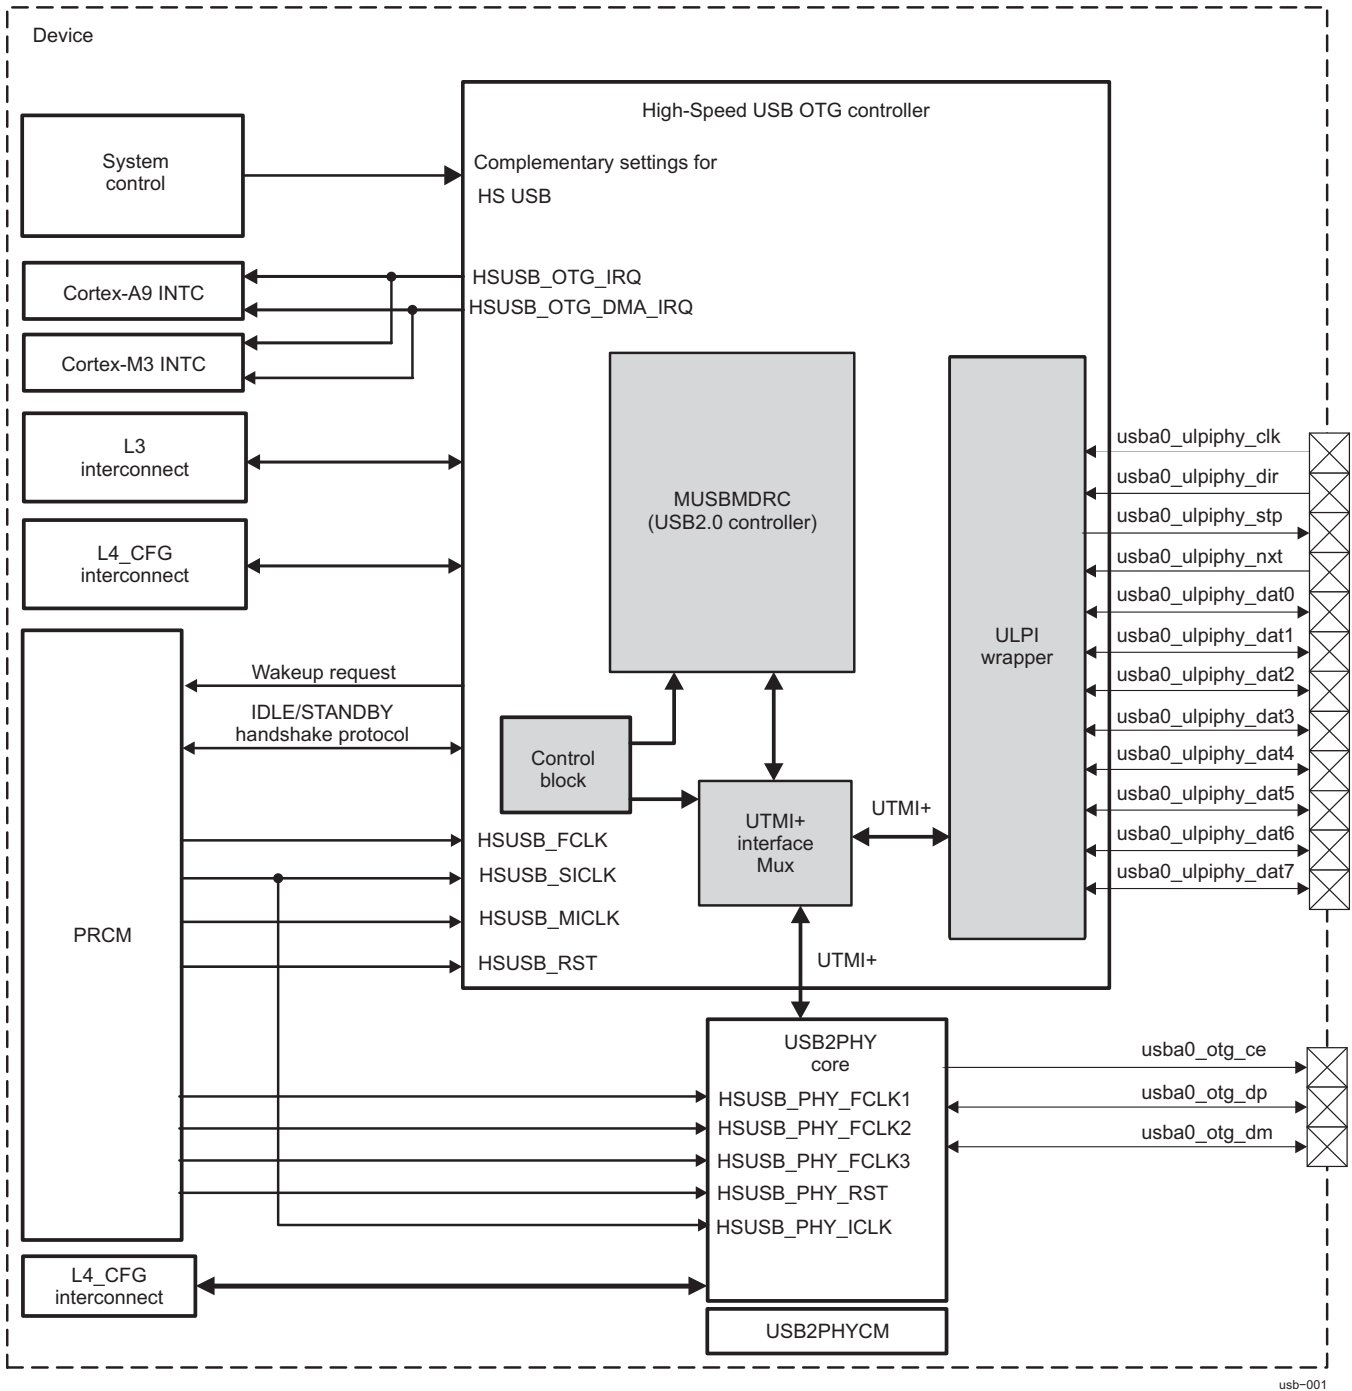

- USB 2.0 peripheral (function controller) in high/full speed (480/12 Mbps, respectively)
- USB 2.0 host in high/full/low speed (480/12/1.5 Mbps, respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 2.0 OTG DRD in high/full speed, with HNP (OTG1.3) and SRP support.

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode) and to connect on D+/D- (+ID) USB bus thanks to an embedded USB-HS OTG PHY.

It is connected to L3 master and L4 slave interfaces. It is clocked from independent functional clock from a PHY. This module operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multi-point communications with other USB functions.

[Figure 23-255](#) highlights the high-speed USB controller.

Figure 23-255. High-Speed USB OTG Controller Highlight

usb-001

### 23.12.1.1 Main Features

The high-speed USB controller features:

- L3 (master) interface supports:
  - 32-bit data bus width
  - 8/16/32 bit access supported
  - 32-bit address bus width
  - Burst supported
  - WNP not supported
- L4 (slave) interface supports:
  - 32-bit data bus width
  - 16/32 bit access supported
  - 12-bit address bus width
  - Burst not supported
  - WNP supported
- Complies with USB2.0 standard for high-speed (480 Mb/s) functions and with the OTG 1.3 (On-The-Go) supplement. Implement Link Power Management
- Contains embedded HS PHY with battery charger detection
- Contains PHY (physical layer) interface: ULPI interface (12-bit version)
- 15 transmit endpoints and 15 receive endpoints in addition to control endpoint 0
- Supports OTG communications with one or more high/full/low speed devices.
- Supports packet splitting / combining for bulk transfers
- Soft connect/disconnect option
- Performs all transaction scheduling in hardware
- Each endpoint can be configured for types (interrupt, bulk or isochronous), for size and double buffering operation within a limit of a 8KB of data and total RAM size of 16KB.
- Supports high-bandwidth isochronous and interrupt transfers.
- Supports suspend/resume and remote wake-up.
- Two interrupt lines.
- DMA access to endpoint FIFOs with internal DMA controller supporting 8 channels
- Supports host negotiation and session request protocols (HNP (OTG1.3) and SRP)
- CarKit feature implementation

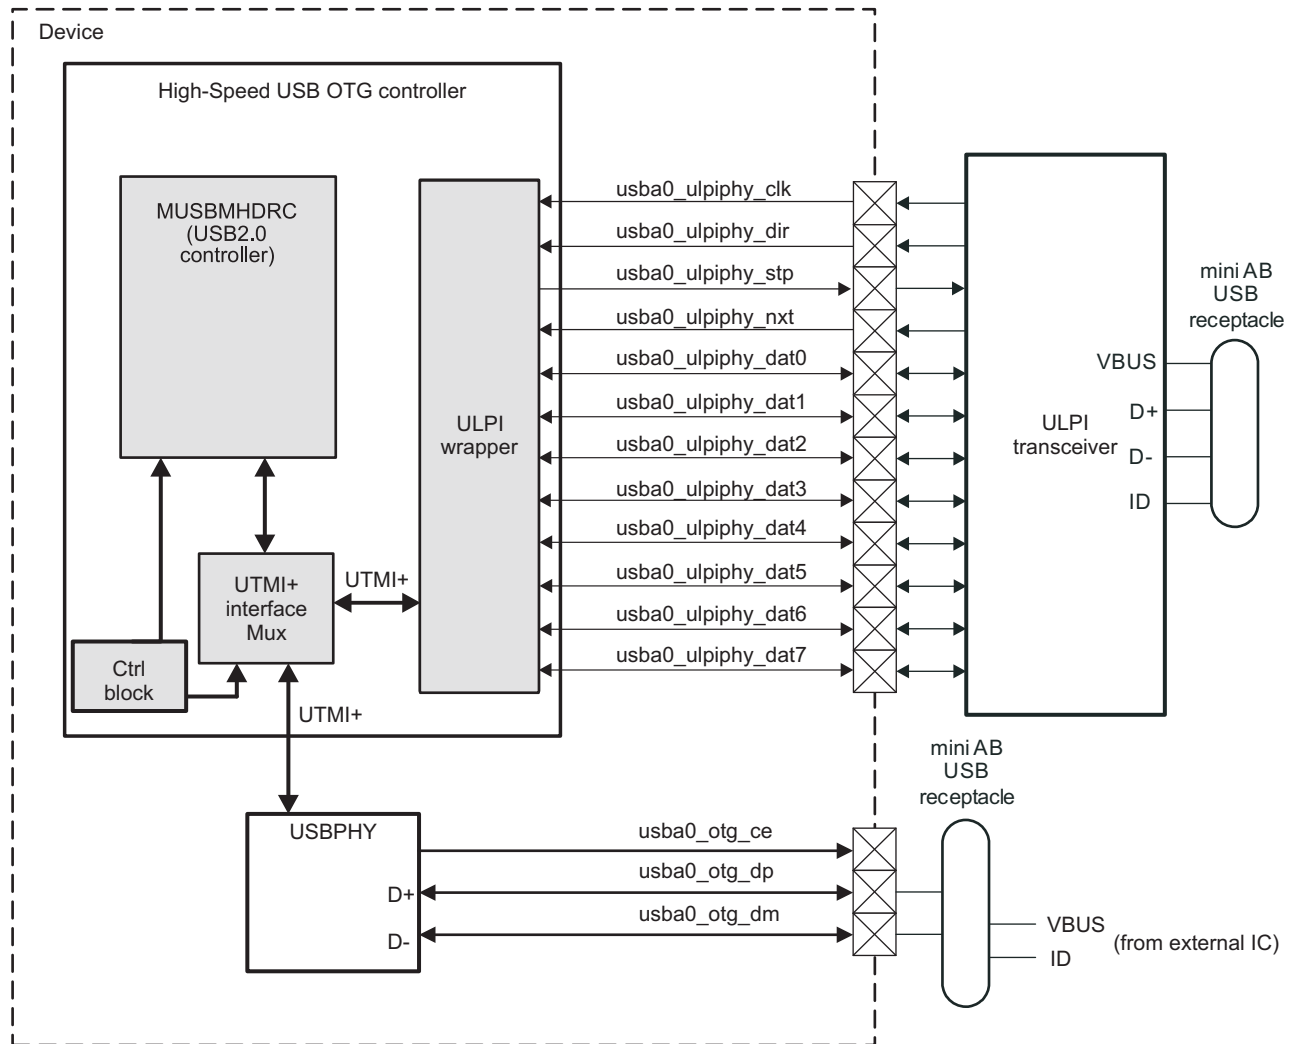

USB-HS OTG PHY (USBPHY). This embedded PHY is composed of two modules:

- USB2PHYCORE contains the USB functions, drivers, receivers and pads for correct D+/D– signalling and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable) to control external battery charger.
- USB2PHYCM contains LDO and bandgap for providing voltage reference to USB2PHYCORE module.

### 23.12.2 High-Speed USB OTG Controller Environment

[Figure 23-256](#) shows a typical application using the high-speed USB controller.

**Figure 23-256. High-Speed USB Controller Typical Application System**

usb-002

**NOTE:** Only one interface can be active at a time.

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode). A mini A-B external receptacle allows the connection of an external device.

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY clock (SDR mode); the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edge (DDR mode).

The current implementation of high-speed USB controller supports only the 12-pin, 8-bit version ULPI interface. The 12-pin/8-bit data SDR ULPI interface is selected through the `OTG_INTERFSEL[2:0]` PHYSEL field and must be set to 0x1.

Embedded PHY interface is 8-bit, UTMI+ and is selected through setting `OTG_INTERFSEL [2:0]` PHYSEL field to 0x0.

### 23.12.2.1 High-Speed USB OTG Controller Functional Interfaces

Table 23-1176 describes the I/O signals of the high-speed USB controller interfaces shown in Figure 23-256

**Table 23-1176. Input/Output Description**

<b>Signal Name</b>	<b>I/O <sup>(1)</sup></b>	<b>Description</b>	<b>Reset Value <sup>(2)</sup></b>
usba0_ulpipiphy_clk	I	Clock input from external transceiver	hi-Z
usba0_ulpipiphy_dir	I	Data direction control from external transceiver	hi-Z
usba0_ulpipiphy_stp	O	Output to external transceiver to stop data stream	1
usba0_ulpipiphy_nxt	I	Next signal control from external transceiver	hi-Z
usba0_ulpipiphy_dat0	I/O	Data 0 to/from external transceiver	hi-Z
usba0_ulpipiphy_dat1	I/O	Data 1 to/from external transceiver	hi-Z
usba0_ulpipiphy_dat2	I/O	Data 2 to/from external transceiver	hi-Z

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

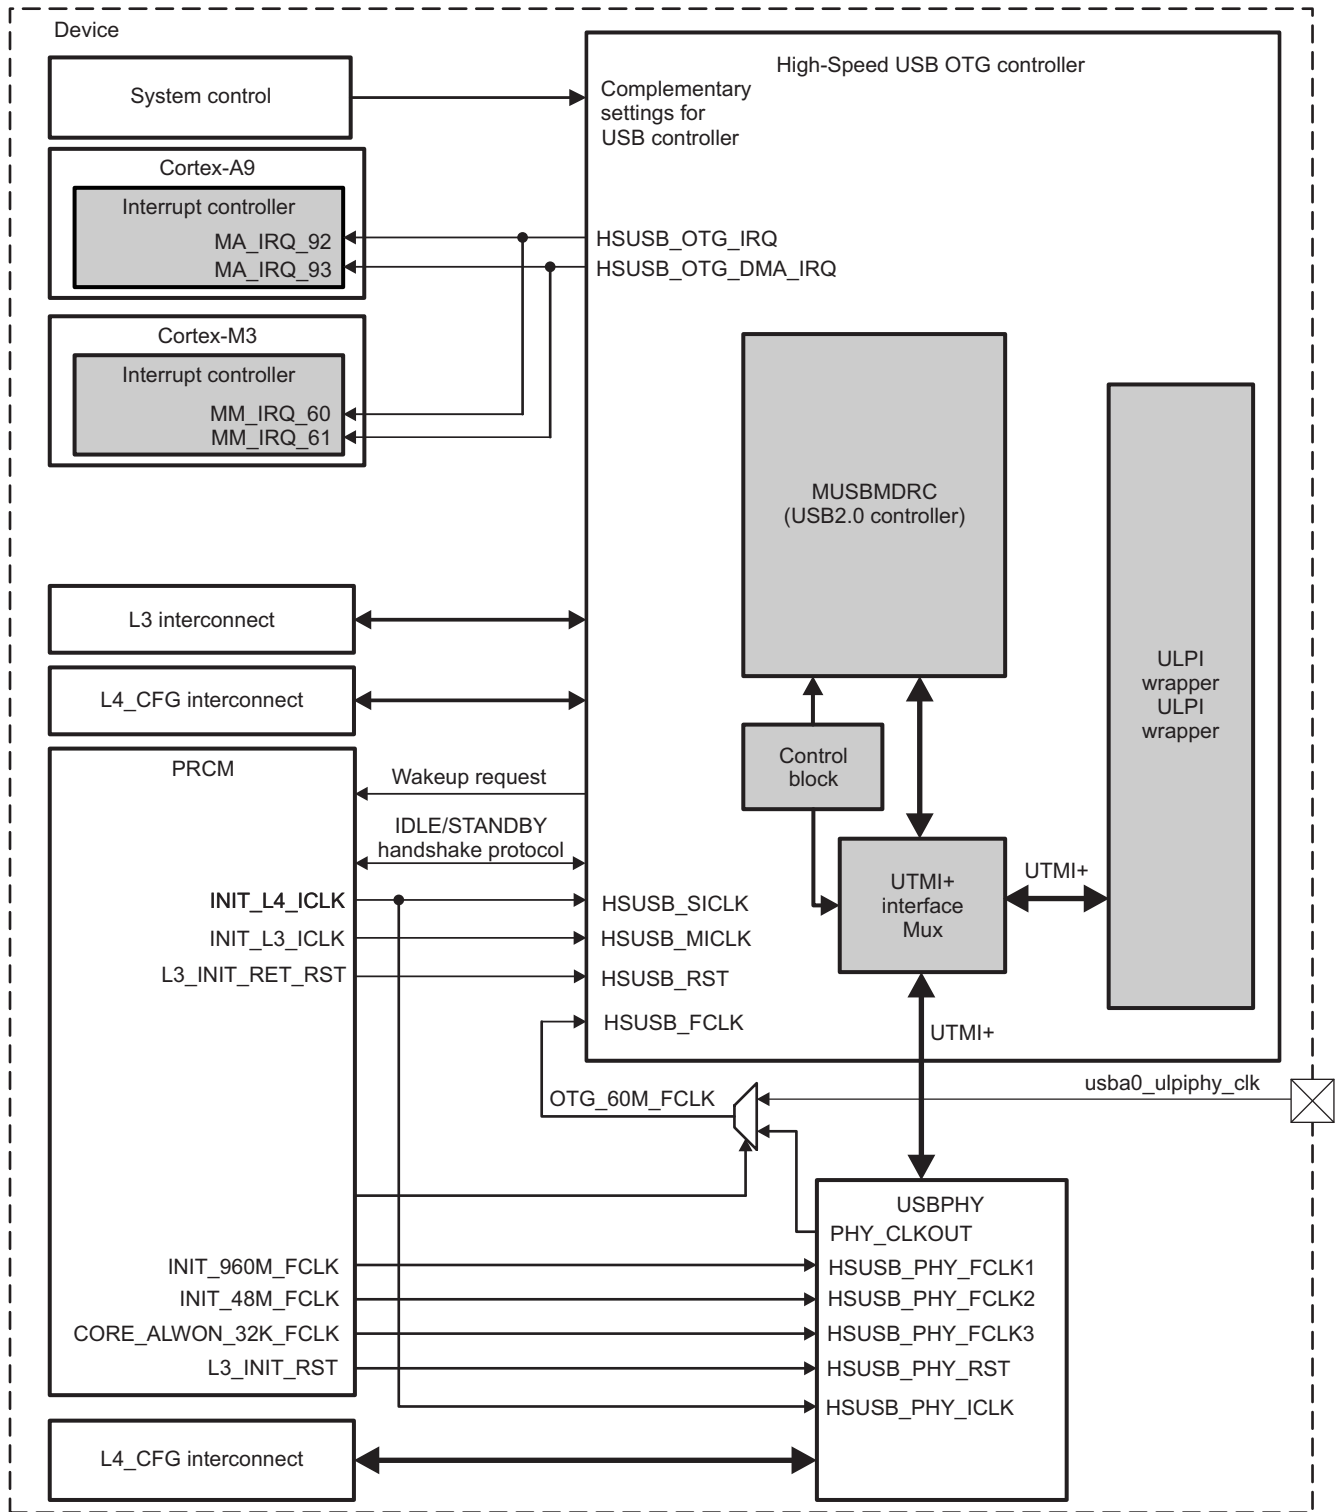

<sup>(2)</sup> hi-Z = High impedance

### 23.12.3 High-Speed USB OTG Controller Integration

The L3 (master) interconnect generates data traffic within the device. The L4(slave) interconnect is a configuration port for register setting.

[Figure 23-257](#) shows the high-speed USB controller integration in the device.

**Figure 23-257. High-Speed USB Controller Integration**

usb-003

Table 23-1177 through Table 23-1179 summarize the integration of the module in the device.

**Table 23-1177. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
HSUSBOTG	PD_L3_INIT	L3 L4_CFG
USBPHY	PD_L3_INIT	L4_CFG

Three clocks are provided to the high-speed USB controller, as listed in [Table 23-1178](#)

**Table 23-1178. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description

## 23.12.4 High-Speed USB OTG Controller Functional Description

### 23.12.4.1 Software Reset

The high-speed USB controller has a software reset through the [OTG\\_SYSCONFIG\[1\] SOFTRESET](#) bit. Writing 0x1 to this bit initiates reset of the module. The bit value 0x1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically cleared to 0x0 and has the same effect as the hardware reset. The status of the reset can be observed through the [OTG\\_SYSSTATUS\[0\] RESETDONE](#) bit.

### 23.12.4.2 Power Management

#### 23.12.4.2.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB OTG functional clock, HSUSB\_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB OTG controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB OTG controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

#### 23.12.4.2.2 System Power Management

##### 23.12.4.2.2.1 Standby Handshake Protocol

The high-speed USB OTG controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB OTG controller has a MSTANDBY handshake mechanism with the PRCM module

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when the USB is in suspend mode and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the [OTG\\_SYSCONFIG\[13:12\] MIDDLEMODE](#) field.

- Smart-standby

The high-speed USB controller is configured in smart-standby mode ([OTG\\_SYSCONFIG\[13:12\] MIDDLEMODE](#) field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force-standby

– When the high-speed USB controller operates as a host: The USBOTG.POWER[1] SUSPENDMODE bit is set to 0x1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. Software must set

**OTG\_SYSCONFIG**[13:12] **MIDLEMODE** = 0x0. Hardware then asserts **MSTANDBY**. Similarly, to release the **MSTANDBY** signal, an appropriate register access must be applied, which can be either of the following two cases:

- Remote wakeup causes a **RESUME** interrupt
  - Set the **USBOTG.POWER**[3] **RESET** bit to 0x1
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] **MIDLEMODE**.
- OR
- Set the **USBOTG.POWER**[3] **RESET** bit to 0x1
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] **MIDLEMODE**.
- When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a **SUSPEND** interrupt is generated by the high-speed USB controller. Software must set **OTG\_SYSCONFIG**[13:12] **MIDLEMODE** = 0x0. Hardware then asserts **MSTANDBY**. The high-speed USB controller then asserts **MSTANDBY**. Similarly, to release the **MSTANDBY** signal, an appropriate register access must be applied, which can be either of the following two cases:
- Set the **USBOTG.POWER**[2] **RESUME** bit to 0x1.
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] **MIDLEMODE**.
- OR
- **RESET** interrupt is generated by the high-speed USB controller.
  - Write 0x2 to the **OTG\_SYSCONFIG**[13:12] **MIDLEMODE**.

When **MSTANDBY** is deasserted as a consequence of the previous register access, the module waits for **MWAIT** deassertion before a DMA transfer is started.

- No-standby

The high-speed USB controller is configured in no-standby mode (**OTG\_SYSCONFIG**[13:12] **MIDLEMODE** field = 0x1). The module never enters standby mode (that is, **MSTANDBY** is never asserted).

Table 23-1180 describes the high-speed USB standby mode settings.

**Table 23-1180. HSUSBOTG Host Controller STANDBYMODE Settings**

<b>OTG_SYSCONFIG</b> [13:12] <b>MIDLEMODE</b> Value	<b>Selected Mode</b>	<b>Description</b>
0x0	Force-standby	The HSUSBOTG host controller enters standby mode unconditionally
0x1	No-standby	The HSUSBOTG host controller never enters standby mode
0x2	Smart-standby	The HSUSBOTG host controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect.

#### **23.12.4.2.2.2 IDLE Handshake Protocol**

The high-speed USB controller can be configured through the **OTG\_SYSCONFIG**[4:3] **SIDLEMODE** field as one of the following acknowledgment modes:

- Smart-idle mode

When the high-speed USB controller receives an **IDLE** request from the **PRCM** module:

- The interface clock **INIT\_L3\_ICLK** is disabled, see [Section 3.6.10, CD\\_L3\\_INIT Clock Domain](#)
- L4 interface clock idle transitions:

Configured in smart-idle mode (**OTG\_SYSCONFIG**[4:3] **SIDLEMODE** field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the **PRCM** module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in smart idle mode (when the **PRCM** module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is

ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from smart idle mode if the `OTG_SYSCONFIG[2] ENABLEWAKEUP` bit is set to 0x1 (wake-up capability enabled).

- Smart-idle wake-up mode

The high-speed USB OTG controller is configured in smart-idle wake-up mode (`OTG_SYSCONFIG[4:3] Smart Idle Wkp` field = 0x3). The functionality of this mode is the same as smart-idle mode, additionally Wake up feature is enabled.

- Force-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock `INIT_L3_ICLK` is disabled, see [Section 3.6.10, CD\\_L3\\_INIT Clock Domain](#)
- The L4 interface clock idle transitions:

Configured in force-idle mode (`OTG_SYSCONFIG[4:3] SIDLEMODE` field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock `INIT_L3_ICLK` is disabled, `CD_L3_INIT Clock Domain`
- L4 interface clock idle transitions

Configured in no-idle mode (`OTG_SYSCONFIG[4:3] SIDLEMODE` bit field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

[Table 23-1181](#) describes the high-speed USB sidle mode settings. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

**Table 23-1181. HSUSBOTG Host Controller SIDLEMODE Settings**

<code>OTG_SYSCONFIG[4:3] SIDLEMODE</code> Value	Selected Mode	Description
0x0	Force-idle	The HSUSBOTG host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations.
0x1	No-idle	The HSUSBOTG host controller never acknowledges any IDLE request from the PRCM.
0x2	Smart-idle	The HSUSBOTG host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated.
0x3	Smart-idle wake-up	The HSUSBOTG host controller enters smart mode with wakeup enabled.

### 23.12.4.2.2.3 Wake-Up Request

Wake-up request is enabled by setting `OTG_SYSCONFIG[2] ENABLEWAKEUP` to 0x1. The enable wake-up feature works only when smart-idle wakeup is enabled.

### 23.12.4.2.3 Local Power Management

The high-speed USB OTG controller has local power management by internal clock gating features:

- Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the `OTG_SYSCONFIG[0] AUTOIDLE` bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

### 23.12.4.3 Inventra MUSBMHDC

The core functionality of the module is provided by a third-party IP, the Inventra™ MUSBMHDC from Mentor Graphics® Corporation.

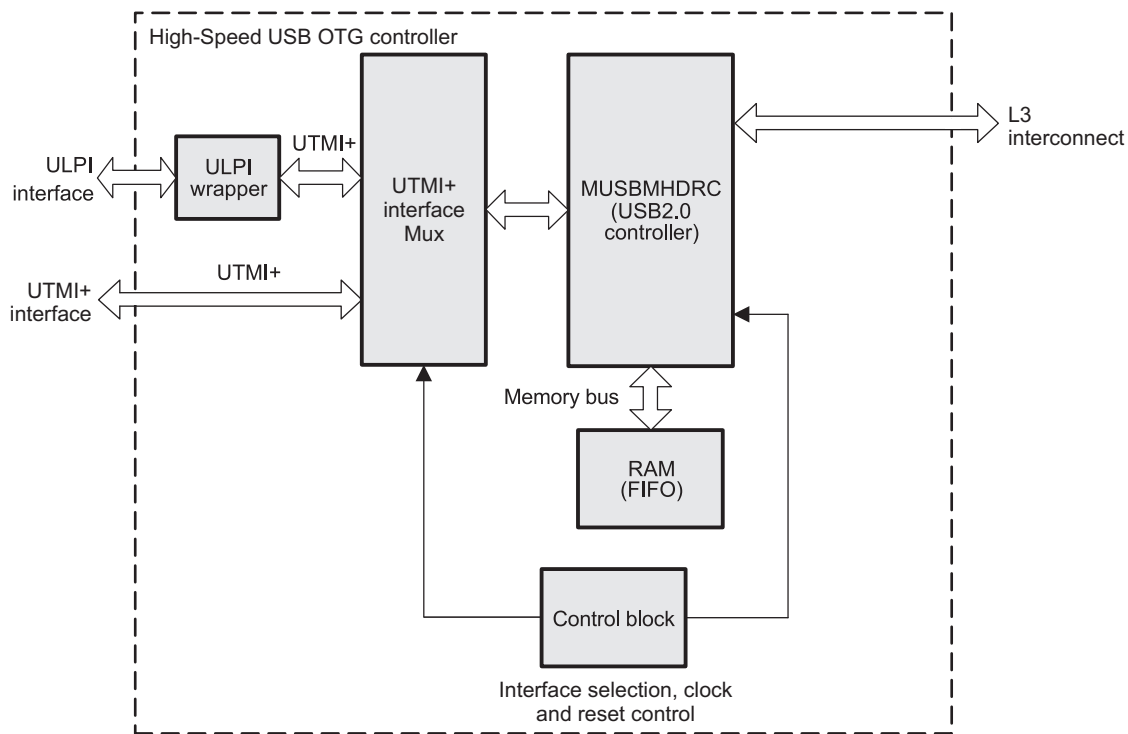

The high-speed USB OTG controller is basically the appropriate adaptation/integration of this IP to comply with TI requirements.

The high-speed USB OTG controller includes the following:

- MUSBMHDC (USB 2.0 controller)
- Master and slave bridges for conversion AHB to L3 interconnect and L3 interconnect to AHB
- Built-in self-test (BIST) controller
- Two memories (total of 16KB; available for various endpoints)
- Reset and clock generation
- DFT compliance with regards to latest specs

Figure 23-258 shows the high-speed USB controller.

Figure 23-258. High-Speed USB OTG Controller

usb-004

### 23.12.4.4 Configuration

The following options are implemented in the TI high-speed USB OTG controller:

- 8-bit internal data path processing width (mandated by the use of ULPI)
- 32-bit vcontrol/vstatus support
- External charge pump: Hacked
- Software connect/disconnect supported
- Little-endian and big-endian byte ordering
- Eight DMA channels (with internal DMA initiator implemented)
- Dynamic FIFO sizing enabled
- 16-KB RAM buffer

- 15 IN/OUT endpoints in addition to control endpoint 0
- IN/OUT bulk packet splitting enabled
- High-bandwidth IN/OUT isochronous support enabled (see *Universal Serial Bus Specification Revision 2.0*)

#### 23.12.4.5 Basic Operation

This section provides an overview of the module basic operation.

To implement the most time-critical functions in hardware, the module provides all of the encoding, decoding, and checking required to send and receive USB packets, interrupting the MPU only when endpoint data is successfully transferred. Generally, the following steps are performed.

##### 23.12.4.5.1 Module Initialization

First, the firmware must do the overall initialization of the module by configuring the interrupts, DMA controller, and individual endpoints.

The specific items of a configuration for each endpoint are:

- Direction TX/RX
- Speed: High/full/low
- Special host settings when used in host mode (function address/hub parameters, etc.)
- Transaction protocol: Control/isochronous/bulk/interrupt
- Maximum packet size, that can be transferred through the endpoint
- Whether DMA is required (DMA enable)
- DMA mode
- Start address of the endpoint FIFO within the RAM block
- Maximum packet size allowed
- Whether double-buffering is required. This and the previous option define the amount of space that must be allocated to the FIFO. In the case of double-buffering, the FIFO size is doubled; therefore, the maximum supported size is 8196 bytes for the endpoint FIFOs.

---

**NOTE:** On the system level, it must be ensured that the reset and the interface are selected before the functional clock (OTG\_60M\_FCLK) is applied to the module. Correct functionality is not ensured if a reset deassertion or a change in the interface selection occurs when the functional clock OTG\_60M\_FCLK is already running.

---

##### 23.12.4.5.2 Transaction Handling

Depending on whether the module is in the host or peripheral mode, an RX endpoint is assigned to IN or OUT transactions, respectively. Similarly, a TX endpoint is used for IN transactions in the peripheral mode and for OUT transactions in the host mode. When a transaction is complete, the appropriate endpoint interrupt is generated (if enabled).

When a transaction is handled through an RX endpoint, the received packet is placed in the RX FIFO, and the appropriate RX endpoint interrupt is generated. The packet can then be unloaded from the FIFO either manually (that is, by the MPU) or by the DMA. Although an RX endpoint is always active for a peripheral, in host mode the transaction must first be initiated by setting the appropriate request flag (REQPKT). This indicates to the transaction scheduler that there is an active transaction on this endpoint, which requires an IN token to be sent to the target function.

When a transaction is handled through a TX endpoint, the packet to send is loaded into the TX FIFO either manually (that is, by the MPU) or by the DMA. The transaction then must be initiated by setting the appropriate ready flag (TXPKTRDY) to indicate the availability of the new packet. When the packet is successfully sent (scheduled according to the protocol rules), the appropriate TX interrupt is generated.

### 23.12.4.6 Optional Features

This section gives a quick overview of the optional features that are available, depending on the endpoint configuration.

#### 23.12.4.6.1 Double Packet Buffering

When double packet buffering is enabled (by setting the MSB of the FIFOSZ register) two data packets can be stored in the FIFO. This option can be set for both the TX and RX endpoints in both the peripheral and host mode. For a TX endpoint, double-buffering means that up to two packets can be loaded into the FIFO awaiting transmission; for an RX endpoint, one packet can be received while another is being read. Double packet buffering is especially advisable for isochronous transactions to avoid underrun or overrun errors.

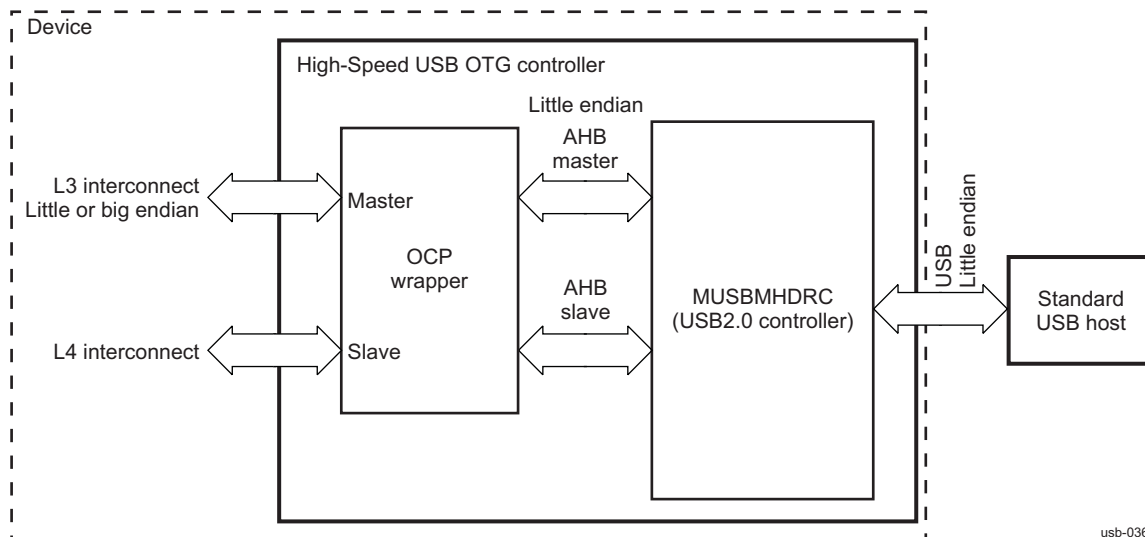

The high-speed USB controller provides dynamic FIFO sizing with an overall RAM size of 16KB, which can then be allocated to the different endpoints when the module is initialized. The maximum size of an endpoint FIFO is 4096 bytes for single packet buffering and 8192 bytes for double packet buffering. The firmware must ensure that a block of RAM is properly assigned to all TX and RX endpoints, considering the total RAM size and the maximum packet size set for the endpoint.

#### 23.12.4.6.2 USBOTGHS Support for Big Endian

In the example in [Figure 23-259](#), the high-speed USB OTG controller module is configured as a USB device and is connected to a standard USB host. The two interconnect interfaces of the high-speed USB OTG controller connect it to the system bus. The register read/write is performed through the interconnect slave interface (control path). The data transfer to/from system memory takes place through the interconnect master interface (data path).

The data transfer on USB is always in little-endian mode, but on interconnect it can be in little- or big-endian mode, as shown in [Figure 23-259](#).

**Figure 23-259. High-Speed USB OTG Controller Endianness**

Big-endian support in the high-speed USB OTG controller may or may not require byte-swapping in the data path. Byte-swapping is performed based on the unit size of data. For example, if multiple bytes are packed into a single 32-bit word, these bytes must be swapped in a big-endian interconnect. On the other hand, if the data is simply a 32-bit word (for example, a 32-bit descriptor pointer in a memory buffer), the bytes in the word must not be swapped in big-endian mode.

In the high-speed USB OTG controller, the unit size of descriptors/descriptor pointers is 32 bits, and the unit size of USB data is 8 bits. Four 8-bit USB data are packed to form a 32-bit word. This 32-bit data requires byte-swapping, whereas the descriptors/descriptor pointers do not require byte-swapping.

**NOTE:** Byte-swapping is not required in the control path (slave interface).

The interconnect master interface (a submodule within the interconnect wrapper) supports big-endian conversion by setting the `OTG_BIGENDIAN[0] BIG_ENDIAN` bit to 0x1.

For interconnect write transactions, the data word is swapped, as shown in [Table 23-1182](#), before its output on the interconnect master interface. In case of an interconnect read transaction, the received data is swapped before its output on the AHB master interface of the MUSBMHDRC core. The interconnect MByteEn is swapped before the command is issued on the interconnect master interface. The interconnect MAddr is always aligned to the size of the interconnect data (32 bits). Hence, the interconnect MAddr is always word-aligned.

**Table 23-1182. Interconnect Data and MByteEn in Little- and Big-Endian Modes**

Unit Size of Data	AHB Size (of Packed/Nonpacked Data)	AHB Start Address Offset (Always in Little-Endian Mode)	Interconnect MByteEn in Little-Endian Mode	Interconnect MByteEn in Big-Endian Mode	Interconnect Data in Little-Endian Mode	Interconnect Data in Big-Endian Mode
Byte	Byte	0	0001	1000	xxx0	0xxx
Byte	Byte	1	0010	0100	xx0x	x0xx
Byte	Byte	2	0100	0010	x0xx	xx0x
Byte	Byte	3	1000	0001	0xxx	xxx0
Byte	Half-word	0	0011	1100	xxb0	b0b1xx
Byte	Half-word	2	1100	0011	b1b0xx	xxb0b1
Byte	Word	0	1111	1111	b3b2b1b0	b0b1b2b3
Half-word	Half-word <sup>(1)</sup>	0	0011	1100	xxb0	b1b0xx
Half-word	Half-word <sup>(1)</sup>	2	1100	0011	b1b0xx	xxb0
Half-word	Word <sup>(1)</sup>	0	1111	1111	b3b2b1b0	b1b0b3b2
Word	Word <sup>(2)</sup>	0	1111	1111	b3b2b1b0	b3b2b1b0

<sup>(1)</sup> Not a likely scenario for high-speed USB OTG controller

<sup>(2)</sup> Corresponds to descriptor and descriptor pointer. No bytes are packed to form a word; hence, no byte-swapping is done in this case.

### 23.12.4.6.3 DMA

The high-speed USB controller has an internal DMA controller for efficient loading/unloading of the endpoint FIFOs. The DMA controller is configured for 8 channels and it has its own block of control registers and its own interrupt controller

If the DMA is enabled for a TX endpoint, a DMA transfer occurs whenever the endpoint can accept another packet in its FIFO (that is, the DMA controller loads the packets into the FIFO without processor intervention).

If the DMA is enabled for an RX endpoint, a DMA transfer occurs whenever the endpoint has a packet in its FIFO (that is, the DMA CONTROLLER unloads the packets from the FIFO without processor intervention).

The high-speed USB controller supports two DMA request modes, which also affects the generation of endpoint interrupts.

- DMA request mode 0 is especially advisable for isochronous transfers but can also be used for bulk and interrupt transfers.
- DMA request mode 1 is mainly valuable for bulk transfers, where typically a large block of data is split into a series of packets of the maximum size.

#### 23.12.4.6.3.1 DMA Request Mode 0

For RX endpoints, the DMA transfer is initiated when a data packet is available in the endpoint FIFO. The appropriate endpoint interrupt is also generated after the packets are received.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is also generated to prompt the loading of the packets.

#### **23.12.4.6.3.2 DMA Request Mode 1**

For RX endpoints the DMA transfer is initiated only when the received packet is the maximum packet size (as set in the RXMAXP register for the corresponding endpoint). The appropriate endpoint interrupt is generated only when the received packet is a short packet (that is, one less than the maximum packet size); otherwise, it is suppressed.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is suppressed.

#### **23.12.4.6.3.3 Internal DMA Controller**

The high-speed USB controller has an internal DMA controller to perform DMA transfers acting as host on the L3 interconnect. The DMA controller has eight channels, which can be independently programmed based on the following configuration options:

- DMA enable
- Direction (DMA write/DMA read)
- DMA mode (transfer one or more packets)
- Interrupt enable
- Endpoint number
- L3 interconnect memory address (32 bits)
- Byte count

The DMA controller can issue single accesses (8-bit, 16-bit, or 32-bit) and also bursts (4 × 32-bit, 8 × 32-bit, or 16 × 32-bit) on the L3 interconnect. The start address provided to the DMA controller must be 32-bit aligned.

#### **23.12.4.7 Automatic Packet Splitting/Combining for Bulk Transfers**

The high-speed USB controller offers the facility for bulk endpoints to store larger amounts of data in their FIFOs than can be transferred in a single USB operation. In other words, the module includes a configuration option that, if selected, allows larger data packets to be written to bulk TX endpoints, which are then split into packets of an appropriate size for transfer across the USB. A similar option exists for bulk RX endpoints, which, if selected, causes the module to combine the packet received across the USB into larger data packets before being read by the application software.

The firmware can enable these options by setting the corresponding bits (MPRXE and MPTXE) in the CONFIGDATA register. The necessary packet size information contains the payload size for one transaction and a multiplier defining the maximum number of USB packets. The payload is required to be either 8, 16, 32, 64, or (in case of high-speed transfers) 512 bytes; the multiplier can be any value up to 32.

#### **23.12.4.8 High-Bandwidth Isochronous Endpoints**

In the high-speed mode, isochronous endpoints can transfer up to three USB packets in any microframe with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per microframe (see *Universal Serial Bus Specification Revision 2.0*).

For TX endpoints, the high-speed USB controller supports this by allowing loading data packets of up to 3072 bytes (that is, 3 × 1024 bytes) into the associated endpoint FIFO, which is then automatically split into USB packets of the maximum payload, or smaller to be transmitted in one microframe.

For RX endpoints, the module automatically combines all the USB packets received during a microframe into a single packet of up to 3072 bytes (that is, 3 × 1024 bytes) within the RX FIFO.

The number of USB packets transferred per microframe and the maximum payload in each packet is defined through the appropriate registers (RXMAXP and TXMAXP).

### 23.12.4.9 Carkit Implementation

Carkit feature implementation:

UART3 RX/TX muxing on the usba0\_ulpihy\_dat0 and usba0\_ulpihy\_dat1. To support carkit interrupt through USB0HS.DATA3, three different methods can be used:

- External PHY interrupt if provided: IRQ\_SYS interrupt
- UART3 interrupt: CTS edge detection
- GPIO interrupt: Edge detection on GPIO associated to usba0\_ulpihy\_dat3 line

### 23.12.4.10 USB PHY

The device-embedded USB PHY is composed of the following modules:

- USB2PHYCORE: Contains the USB functions, drivers, receivers, and pads for correct D+/D- signaling, and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable [pin usba0\_otg\_ce]) to control an external battery charger.
- USB2PHYCM: Contains LDO and bandgap to provide voltage reference to the USB2PHYCORE module

The embedded PHY does not support the OTG features of USB-OTG standards (that is, ID pin detection and VBUS detection). This function is exported to an external companion chip (for example, the TWL6030). Software must retrieve the OTG HNP and SRP status from the TWL6030 (using the I2C1 interface) and configure the bits inside the control module that drive the related USBOTGHS UTMI+ interface signals. It must also read back the UTMI+ signals needed to configure the TWL6030 OTG module.

These signals are:

- Inputs of the USB controller driven by the control module:
  - Avalid: Indicates whether VBUS is above the A-Device session valid threshold
  - Bvalid (currently not used)
  - Vbusvalid: Indicates whether VBUS is above the threshold for normal operation
  - Sessend: Indicates whether VBUS is below the B-Device session end threshold
  - Iddig: Indicates the value of the ID pin of the USB connector
- Outputs of the USB controller readable in the control module:
  - Idpullup: Enables sampling of the ID pin of the USB connector
  - Drv vbus: Controls the driving of 5-V power on VBUS
  - Chrg vbus: Controls the charging of VBUS for initiating SRP
  - Dischrg vbus: Controls the discharging of VBUS for completing SRP

See the CONTROL\_USBOTGHS\_CONTROL register in [Chapter 18, Control Module](#), and the TWL6030 documentation.

The following UTMI signals are not connected:

- Txbistuffenable (no bit-stuffing out from the USB controller)
- Txbistuffenableh (because only 8 bits are used)

The following USBPHY signals are routed internally to the GPIO6 module pins to generate interrupts when any of the following events occur:

- CHGDETECTED: This signal indicates the output of the charger detection protocol.
  - 0: Charger not detected
  - 1: Charger detected

The value is latched until the charger protocol is reset.

- DPDM5VSHORT: This signal is asserted high if a short-circuit-to-VBUS condition is detected on the USB DP or DM pins. This signal is valid only if all power supplies are present. The short is detected if any or even none of the supplies are present.
  - 0: No short

1: VBUS short on DP or DM detected

For information about how to enable these interrupts, see [Chapter 25, General-Purpose Interface](#).

The USBPHY internal registers are listed in [Section 23.12.6.3, USBPHY Registers](#), for debug purposes.

**CAUTION**

For a correct read out of the USBPHY registers, the value of the [OCP2SCP\\_TIMING\[3:0\]](#) SYNC2 bit field must be set to 0x6 or more, and the [OCP2SCP\\_TIMING\[9:7\]](#) DIVISIONRATIO bit field must be left untouched.

### 23.12.5 High-Speed USB OTG Controller Basic Programming Model

This section describes the low-level hardware programming sequences for configuration and use of the high-speed USB OTG controller.

#### 23.12.5.1 Global Initialization

##### 23.12.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the high-speed USB OTG controller is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the high-speed USB OTG controller.

**Table 23-1183. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	All required clocks must be enabled, see <a href="#">Table 23-1178</a> . Do not apply OTG_60M_FCLK clock before the interface is selected. Refer to <a href="#">Section 3.6.3.2, CM Clock Source</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Cortex-A9 MPU INTC or Cortex-M3 MPU INTC	Cortex-A9 MPU or Cortex-M3 MPU interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the High-Speed Multiport USB Host Subsystem. See the respective Functional Description in the Interrupt Controller chapter for the MPUs.
Interconnect (L3 and L4)	See <a href="#">Section 13.2, L3 Interconnect</a> , and <a href="#">Section 13.3, L4 Interconnect</a> , for more information.

##### 23.12.5.1.2 High-Speed USB OTG Controller Global Initialization

This procedure initializes the high-speed multiport USB host subsystem after a power-on or software reset. The module USBPHY is reset through boundary reset signal L3\_INIT\_RST coming from PRCM module.

**Table 23-1184. High-Speed USB OTG Software Reset**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset on the USB OTG controller	<a href="#">OTG_SYSCONFIG[1]</a> SOFTRESET	0x1
Wait until reset is finished	<a href="#">OTG_SYSSTATUS[0]</a> RESETDONE	=0x1

**Table 23-1185. Power Management Configuration**

Step	Register/Bit Field/Programming Model	Value
Select master interface standby mode	<a href="#">OTG_SYSCONFIG[13:12]</a> MIDDLEMODE	0x-
Select slave interface idle mode	<a href="#">OTG_SYSCONFIG[4:3]</a> SIDLEMODE	0x-

**Table 23-1185. Power Management Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Set clock autogating	OTG_SYSCONFIG[0] AUTOIDLE	0x-

### 23.12.5.2 High-Speed USB OTG Controller Interface Modes

This procedure describes TI high-speed USB controller interface selection:

**Table 23-1186. High-Speed USB Controller Interface Selection**

Step	Register/Bit Field/Programming Model	Value
Select between embedded and external PHY interface	OTG_INTERFSEL[2:0] PHYSEL	0x-
Enable functional PHY clock (OTG_60M_FCLK)	Refer to	-

### 23.12.5.3 High-Speed USB OTG Controller Power Management Configuration

This section describes the settings for optimal high-speed USB controller power management, depending on the use of this module in the application.

#### 23.12.5.3.1 No Application Mode

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

**Table 23-1187. Power Management Configuration - No Application Mode**

Step	Register/Bit Field/Programming Model	Value
Switch master interface to force standby mode	OTG_SYSCONFIG[13:12] MIDDLEMODE	0x0
Switch slave interface to force-idle mode	OTG_SYSCONFIG[4:3] SIDLEMODE	0x0
Set the clock to smart mode - clock is cut-off if no activity on the interface	OTG_SYSCONFIG[0] AUTOIDLE	0x1

#### 23.12.5.3.2 Host or Peripheral Mode

When used as a host or in peripheral mode, the high-speed USB controller must be programmed as follows:

**Table 23-1188. Power Management Configuration - Host or Peripheral Mode**

Step	Register/Bit Field/Programming Model	Value
Switch Master interface to smart standby mode	OTG_SYSCONFIG[13:12] MIDDLEMODE	0x2
Switch Slave interface to smart-idle mode	OTG_SYSCONFIG[4:3] SIDLEMODE	0x2
Set the clock to smart mode - clock is cut-off if no activity on the interface	OTG_SYSCONFIG[0] AUTOIDLE	0x1

#### 23.12.5.3.3 Switching Between Host and Peripheral Mode

When used as a host/peripheral, the high-speed USB OTG controller must be programmed as follows:

**Table 23-1189. Power Management Configuration - Switching Between Host and Peripheral Mode**

Step	Register/Bit Field/Programming Model	Value
Switch Master interface to force standby mode	OTG_SYSCONFIG[13:12] MIDDLEMODE	0x0
Switch Slave interface to smart-idle mode	OTG_SYSCONFIG[4:3] SIDLEMODE	0x2
Set the clock to smart mode - clock is cut-off if no activity on the interface	OTG_SYSCONFIG[0] AUTOIDLE	0x1

## 23.12.6 High-Speed USB OTG Controller Register Manual

This section presents only the TI-specific registers of the high-speed USB controller.

Table 23-1190 lists the base address and address space for the high-speed USB controller.

**Table 23-1190. High-Speed USB OTG Controller Instance Summary**

Module Name	Base Address	Size
HSUSBOTG	0x4A0A B000	4KB
OCP2SCP	0x4A0A D000	64 bytes
USBPHY	0x4A0A D080	3968 bytes

### 23.12.6.3 USBPHY Registers

#### 23.12.6.3.1 USBPHY Register Summary

**CAUTION**

The USBPHY registers are limited to 32-bit data accesses; 16- and 8-bit accesses are not allowed and can corrupt register content.

Reserved bit fields must not be modified.

**NOTE:** No USB2PHY register settings need to be done in order USB2PHY to operate in default USB2.0 (HS, FS, or LS mode) condition. Registers are provided only for debug purposes.

**Table 23-1215. USBPHY Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

## 23.13 Full-Speed USB Host Controller

This section describes the full-speed universal serial bus (FSUSB) host controller for the device.

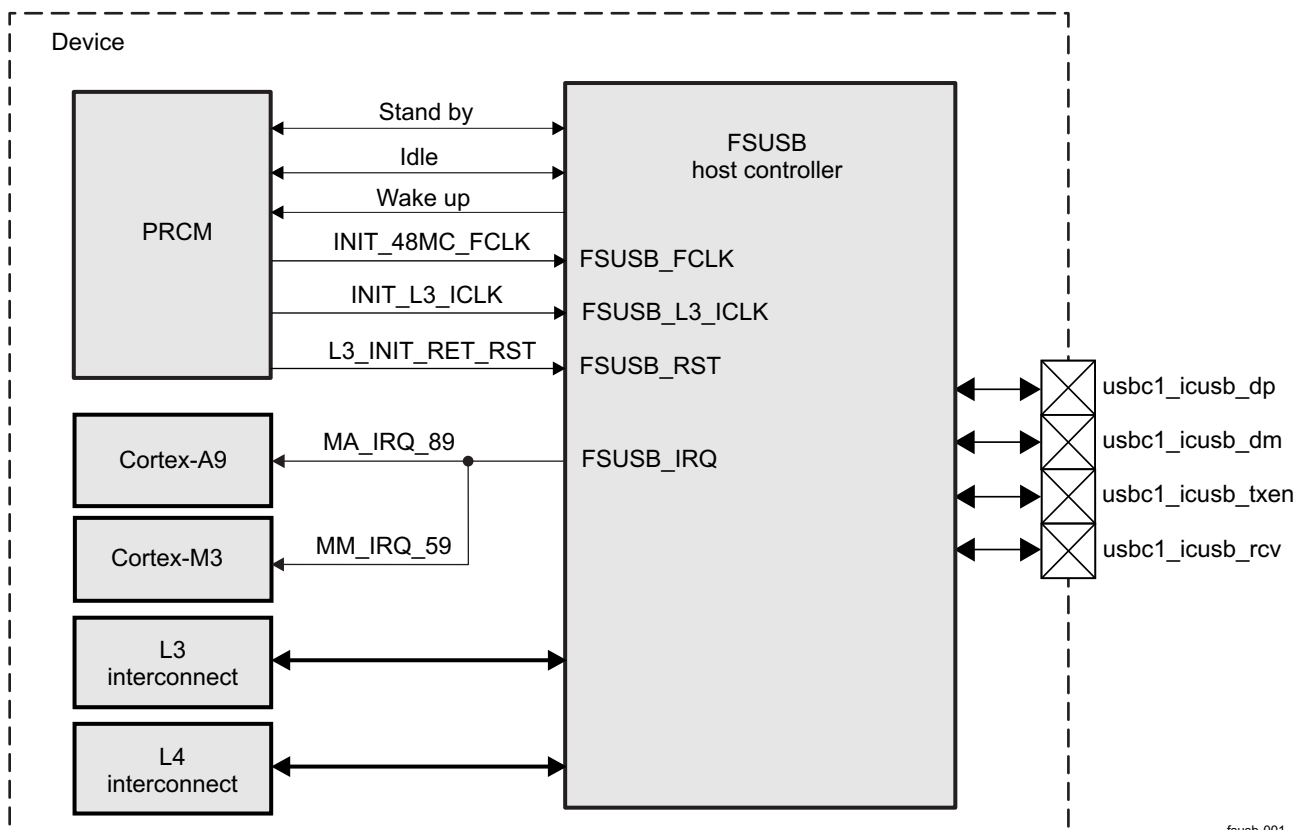

### 23.13.1 FSUSB Host Controller Overview

**NOTE:** Copyright ©2004, 2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

This module is a full-speed universal serial bus (FSUSB) host controller which complies with the USB 2.0 standard for full-speed functions. The FSUSB host controller supports a single universal serial bus (USB) host port with a USB interchip to interface with a multimedia subscriber-identity module (SIM) card, using 2-/4-pin bidirectional mode (host mode).

The FSUSB host controller has level 3 (L3) and level 4 (L4) interfaces with an independent functional clock.

**Figure 23-260. FSUSB Host Controller Overview**

fsusb-001

#### 23.13.1.1 Main Features

The main features of the FSUSB host controller include:

- USB host
  - Compatible with OHCI Rev 1.0
  - USB 2.0 low-speed (1.5 Mbps) and full-speed (12 Mbps) operations
  - Single port
- USB port signal pins interface:
  - Only supports the 2-/4-pin (bidirectional) mode
- Slave interface (L4) supporting:

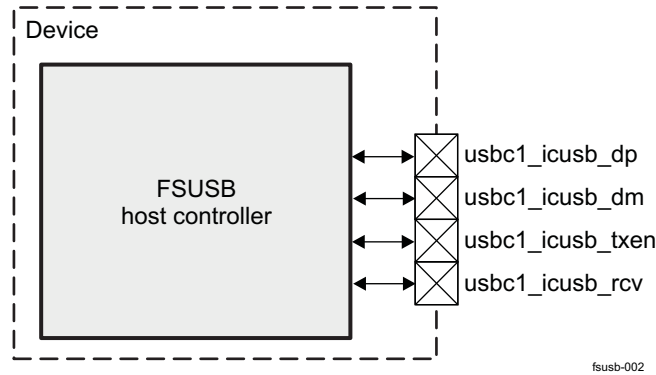

- 32-bit data bus width
- 32-bit access
- 32-bit address bus width
- Wireless network portability (WNP)
- Burst is not supported
- Master interface (L3) supporting:
  - 32-bit data bus width
  - 8-/32-bit access
  - 32-bit address bus width
  - Write nonposted (WRPN) interconnect transaction

### 23.13.2 FSUSB Host Controller Environment

This section describes the FSUSB host controller application fields from an environment point of view (external connections). It discusses FSUSB host controller connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

Figure 23-261 shows the output pins of the FSUSB host controller.

Figure 23-261. Overview of FSUSB Host Controller Environment

#### 23.13.2.1 FSUSB Host Controller Functional Interfaces Description

Table 23-1228 and Table 23-1229 list the input/output (I/O) signals.

Table 23-1228. Pin List for FS USB-Host (USB-Interchip Mode)

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
usbc1_icusb_dp	I/O	Interchip FSUSB host controller D plus	Unknown
usbc1_icusb_dm	I/O	Interchip FSUSB host controller D minus	Unknown

<sup>(1)</sup> I = Input, O = Output

Table 23-1229. 4-Pin Mode Delivered on Pin (for External Transceiver Connection)

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value
usbc1_icusb_dp	I/O	FSUSB host controller D plus	Unknown
usbc1_icusb_dm	I/O	FSUSB host controller D minus	Unknown
usbc1_icusb_txen	O	FSUSB host controller transmit enable	Unknown
usbc1_icusb_rcv	I	FSUSB host controller receive	Unknown

<sup>(1)</sup> I = Input, O = Output

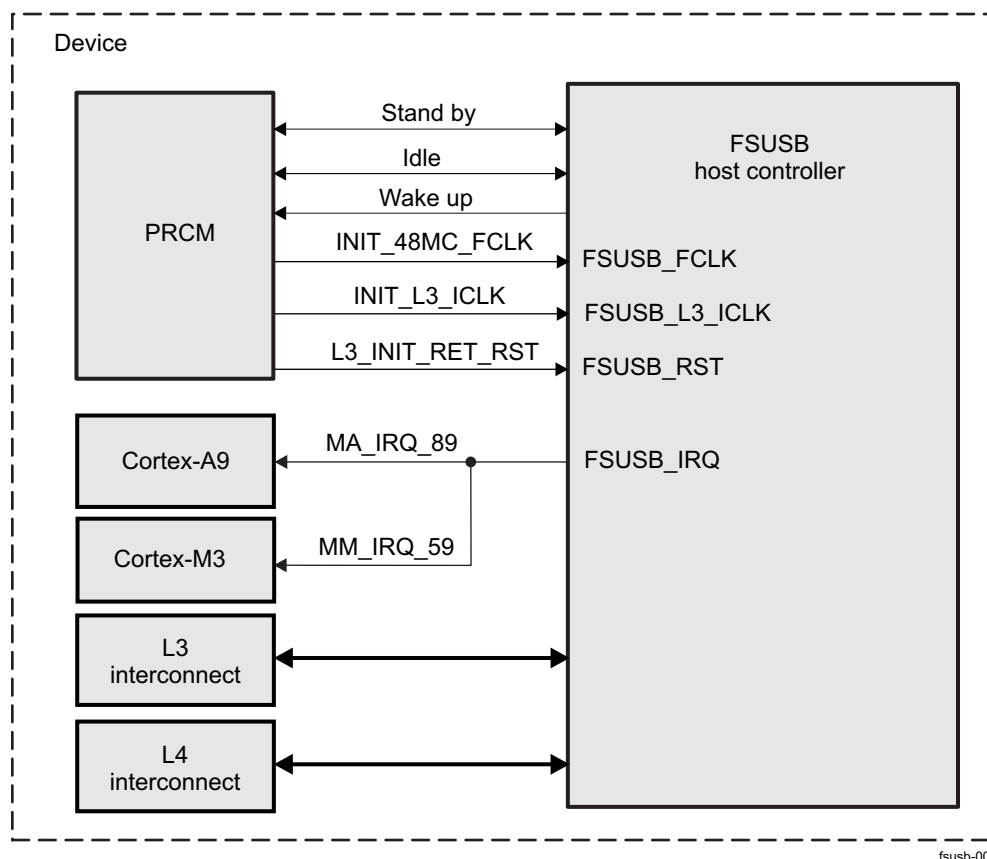

### 23.13.3 FSUSB Host Controller Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-262 shows the integration of the FSUSB host controller in the device.

**Figure 23-262. FSUSB Host Controller Integration**

fsusb-004

Table 23-1230 through Table 23-1232 summarize the integration of the module in the device.

**Table 23-1230. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
FSUSB host controller	PD_L3_INIT	L3 L4_CFG

**Table 23-1231. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
FSUSB host controller	FSUSB_FCLK	INIT_48MC_FCLK	PRCM	Functional clock (see Section 3.6.10, <i>CD_L3_INIT Clock Domain</i> in Chapter 3, <i>Power, Reset, and Clock Management</i> ).
	FSUSB_L3_ICLK	INIT_L3_ICLK	PRCM	L3 interconnect clock for the L3 master port interface (see , <i>CD_L3_INIT Clock Domain</i> in Section 3.6.10, <i>Power, Reset, and Clock Management</i> )

**Table 23-1231. Clocks and Resets (continued)**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
	FSUSB_L4_ICLK	INIT_L4_ICLK	PRCM	L4 interconnect-enable signal for the slave interface on L4 (see <a href="#">Section 3.6.3.2, CM Clock Source</a> in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> )
Resets				
FSUSB host controller	FSUSB_RST	L3_INIT_RET_RST	PRCM	This signal resets the FSUSB host controller module.

**Table 23-1232. Hardware Requests**

Interrupt Requests					
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description	
FSUSB controller	host FSUSB_IRQ	MA_IRQ_89	Cortex-A9 INTC	Destination is Cortex-A9 interrupt controller (INTC)	
	FSUSB_IRQ	MM_IRQ_59	Cortex-M3 INTC	Destination is Cortex-M3 INTC	

---

**NOTE:** For interrupt source information, see [Section 23.13.5.1.2, Interrupt Requests](#).

---

## 23.13.4 FSUSB Host Controller Functional Description

### 23.13.4.1 Resets

The different software reset functions of the FSUSB host controller are controlled by the following register bits:

- **HCOCPYSYS[1] SOFT\_RESET** bit: Writing 0x1 to this bit resets the entire module, except IDLE, STANDBY, and DISCONNECT logic. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFT\_RESET bit is automatically set to 0x0.
- **HCCOMMANDSTATUS[0] HCR** bit: Writing 0x1 resets most of the open host controller interface (OHCI) registers of the FSUSB host controller. It is useful for error handling only. OHCI register accesses must not be attempted until a read of this register returns 0x0.

### 23.13.4.2 Power Management

#### 23.13.4.2.1 Features

The power management module has the following features:

- The FSUSB host controller has one instance of IDLE and standby interface.
- There are separate disconnect interfaces for master and slave ports.
- The PRCM module uses IDLE protocol to put the FSUSB host controller asynchronous into idle mode.
- The FSUSB host controller uses standby protocol for USB suspend event.
- Clock gating is done externally for IDLE and standby protocol.
- The IDLE and STANDBY interfaces are synchronous to the PRCM clock.

#### 23.13.4.2.2 IDLE Protocol

The IDLE protocol has the following features:

- There is one IDLE protocol for the FSUSB host controller.
- The **HCOCPYSYS[3:2] IDLE\_MODE** bit field controls the way USBFHOST handles the IDLE protocol.
- The FSUSB host controller WakeupEnable mode is enabled by setting the **HCOCPYSYS[3:2] IDLE\_MODE** bit field to 0x11.
- Wakeup is generated asynchronously in the FSUSB host controller. To detect the USB remote wakeup, the FSUSB host controller should always be powered up (that is, the clocks can be off, but the power is needed for a wake-up detection to work).
- The FSUSB host controller interface asserts wakeup from suspend when the wake-up conditions occur (such as remote signaling on port, device connect/disconnect) and the FSUSB host controller is in idle mode. The FSUSB host controller interface deasserts the wake-up signal when the PRCM module has serviced the event (usually at completion of a resume sequence on the USB) and IDLE request is 0.
- The FSUSB host controller interface acknowledges and goes into IDLE only if the host controller is in suspend mode, or if force-idle mode is enabled.

Table 23-1233 lists the FSUSB host controller idle mode settings.

**Table 23-1233. FSUSB Host Controller Idle Mode Settings**

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The high-speed USB host controller unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations.
0x1	Not supported (no-idle)	
0x2	Smart-idle	The high-speed USB host controller acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledged signal is asserted only when all pending transactions, IRQs, or DMA requests are treated.
0x3	Smart-idle wakeup	The high-speed USB host controller enters smart mode with asynchronous wakeup enabled.

### 23.13.4.2.3 Standby Protocol

The Standby protocol is associated with FSUSB host controller suspend. Standby assertion is linked with Suspend, and Wakeup assertion is linked with remote wakeup. When the application wants to resume the USB, the power manager must initiate the wakeup using the Standby protocol.

- There is one Standby protocol for the FSUSB host controller.
- The `HCOCPSYS[5:4]` STANDBY\_MODE bit field controls the way USBFSHOST handles the Standby protocol.
- The FSUSB host controller wakes up with standby, and stays in standby until the host core becomes functional.

Table 23-1234 lists the STANDBY\_MODE settings for the FSUSB host controller.

**Table 23-1234. FSUSB Host Controller STANDBY\_MODE Settings**

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The high-speed USB host controller enters standby mode unconditionally (Mstandby is asserted unconditionally).
0x1	Not supported (no-standby)	
0x2	Smart-standby	The high-speed USB host controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect.
0x3	Smart-standby wakeup	The high-speed USB host controller enters smart mode with asynchronous wakeup enabled.

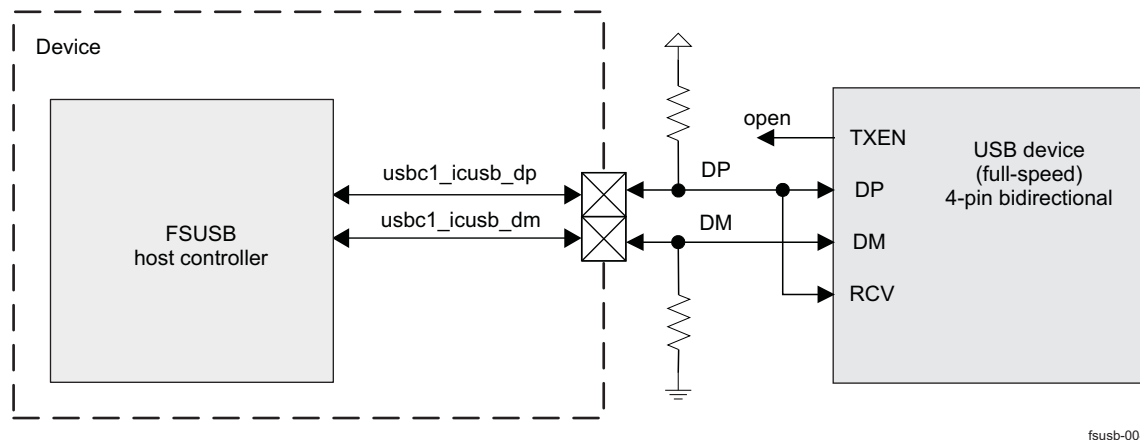

### 23.13.4.3 FSUSB Host Controller Bidirectional Interface Modes

Bidirectional SIM interface modes are implemented using existing bidirectional modes. Their goal is to reduce pin count with respect to 6-/5-pin modes.

Pullup/pulldown resistors on the bidirectional lines are compulsory, because the lines are not constantly driven from one side or the other of the interface. In this case, the pullup on one of the two lines triggers the connect signal from the device to the host. The pullup can be controlled (by the USB device side) or hardwired. In the first case, the USB host sees only the external device if the pullup is active; in the second case, the USB host sees the device as soon as software enables the port in question.

The device supports the 2-pin bidirectional SIM Interface mode with DP/DM encoding. Figure 23-263 shows a USB port using DP/DM encoding.

**Figure 23-263. 2-Pin Bidirectional Interface Using DP/DM Encoding With a Standard 4-Pin Bidirectional USB Device**

fsusb-004

A specific 2-pin USB device can also be implemented with just the two bidirectional pins. Figure 23-264 shows an example in DP/DM encoding with built-in pullup/pulldown resistors.

**Figure 23-264. 2-Pin Bidirectional Interface Using DP/DM Encoding With a Specific 2-Pin Bidirectional USB Device**

### 23.13.5 FSUSB Host Controller Basic Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the FSUSB host controller.

#### 23.13.5.1 Global Initialization

##### 23.13.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the FSUSB host controller is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the FSUSB host controller.

[Table 23-1235](#) describes the global initialization of the surrounding modules.

**Table 23-1235. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	All clocks must be enabled (see <a href="#">Table 23-1231</a> ). See <a href="#">Section 3.6.3.2, CM Clock Source</a> in <a href="#">Chapter 3, Power, Reset and Clock Management</a> .
Cortex-A9 MPU INTC or Cortex-M3 MPU INTC	The Cortex-A9 MPU or Cortex-M3 MPU INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the FSUSB host controller. See the respective functional description in <a href="#">Chapter 17, Interrupt Controllers</a> , for the MPUs.
Interconnect (L3 and L4)	For more information, see <a href="#">Section 13.2, L3 Interconnect</a> , and <a href="#">Section 13.3, L4 Interconnect</a> .

**NOTE:** This module requires an active functional clock for L4 access to function.

##### 23.13.5.1.2 FSUSB Host Controller Global Initialization

This procedure initializes the FSUSB host controller after a power-on or software reset (see [Table 23-1236](#)).

**Table 23-1236. High-Speed Multiport USB Host Subsystem Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Perform a software reset on the FSUSB host controller module, except for IDLE, STANDBY, and DISCONNECT logics.	HCOCPSYS[1] SOFT_RESET	0x1

**Table 23-1236. High-Speed Multiport USB Host Subsystem Global Initialization (continued)**

<b>Step</b>	<b>Register/Bit Field/Programming Model</b>	<b>Value</b>
Wait until reset is finished.	<a href="#">HCOCPSYS</a> [1] SOFT_RESET	0x0
Enable IRQ event for the FSUSB host controller.	<a href="#">HCINTERRUPTENABLE</a> [31] MIE	0x1
Enable IRQ event for each function of the FSUSB host controller.	<a href="#">HCINTERRUPTENABLE</a> [6:0] xxx	0x1

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	USBFSHOST
<b>Physical Address</b>	0x4A0A 9010		
<b>Description</b>	HC Interrupt Enable		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MIE	OC	RESERVED														RHSC	FNO	UE	RD	SF	WDH	SO									

Bits	Field Name	Description	Type	Reset
31	MIE	Master interrupt enable When 0x1: Allows other enabled OHCI interrupt sources to propagate to the device interrupt controller. When 0x0: OHCI interrupt sources are ignored. Write 0x0: No effect Write 0x1: Sets this bit	RW	0
30	OC	Ownership change	RW	0
29:7	RESERVED	Reserved	R	0x000000
6	RHSC	Root hub status change When 0x1 and MIE is 0x1: Allows root hub status change interrupts to propagate to the device interrupt controller. When 0x0 or MIE is 0x0: root hub status change interrupts do not propagate. Write 0x0: No effect Write 0x1: Sets this bit	RW	0
5	FNO	Frame number overflow. When 0x1 and MIE is 0x1: Allows FNO interrupts to propagate to the device interrupt controller. When 0x0 or MIE is 0x0: FNO interrupts do not propagate. Write 0x0: No effect Write 0x1: Sets this bit	RW	0
4	UE	Unrecoverable error. When 0x1 and MIE is 0x1: Allows UE interrupts to propagate to the device interrupt controller. When 0x0 or MIE is 0x0: UE interrupts do not propagate. Write 0x0: No effect Write 0x1: Sets this bit	RW	0
3	RD	Resume detected. When 0x1 and MIE is 0x1: Allows RD interrupts to propagate to the device interrupt controller. When 0x0 or MIE is 0x0: RD interrupts do not propagate. Write 0x0: No effect Write 0x1: Sets this bit	RW	0
2	SF	Start of frame When 0x1 and MIE is 0x1: Allows SF interrupts to propagate to the device interrupt controller. When 0x0 or MIE is 0x0: SF interrupts do not propagate. Write 0x0: No effect Write 0x1: Sets this bit	RW	0
1	WDH	Write done head When 0x1 and MIE is 0x1: Allows WDH interrupts to propagate to the device interrupt controller. When 0x0 or MIE is 0x0: WDH interrupts do not propagate. Write 0x0: No effect Write 0x1: Sets this bit	RW	0
0	SO	Scheduling overrun. When 0x1 and MIE is 0x1: Allows SO interrupts to propagate to the device interrupt controller. When 0x0 or MIE is 0x0: SO interrupts do not propagate. Write 0x0: No effect Write 0x1: Sets this bit	RW	0

## MMC/SD/SDIO

This chapter describes the features and functions of the multimedia card/SD card (MMC/SD/SDIO) interface of the device.

Topic	Page
24.1 MMC/SD/SDIO Overview .....	5502
24.2 MMC/SD/SDIO Environment .....	5509
24.3 MMC/SD/SDIO Integration .....	5517
24.4 MMC/SD/SDIO Functional Description .....	5520
24.5 MMC/SD/SDIO Programming Guide .....	5549
24.6 MMC/SD/SDIO Register Manual .....	5575

## 24.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SDIO (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the level 3 (L3) interconnect to have a direct access to system memory. It also supports two direct memory access (DMA) slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration. These controllers are embedded MMC/SD (eMMC/SD) controllers.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are five MMC/SD/SDIO host controllers inside the device:

[Figure 24-1](#) gives an overview of the MMC/SD/SDIO1 controller instance (eMMC/SD).

[Figure 24-2](#) gives an overview of the MMC/SD/SDIO2 controller instance (eMMC/SD).

[Figure 24-3](#) gives an overview of the MMC/SD/SDIO3 through MMC/SD/SDIO5 controller instances.

Figure 24-1. MMC/SD/SDIO1 Overview (where i = 1)

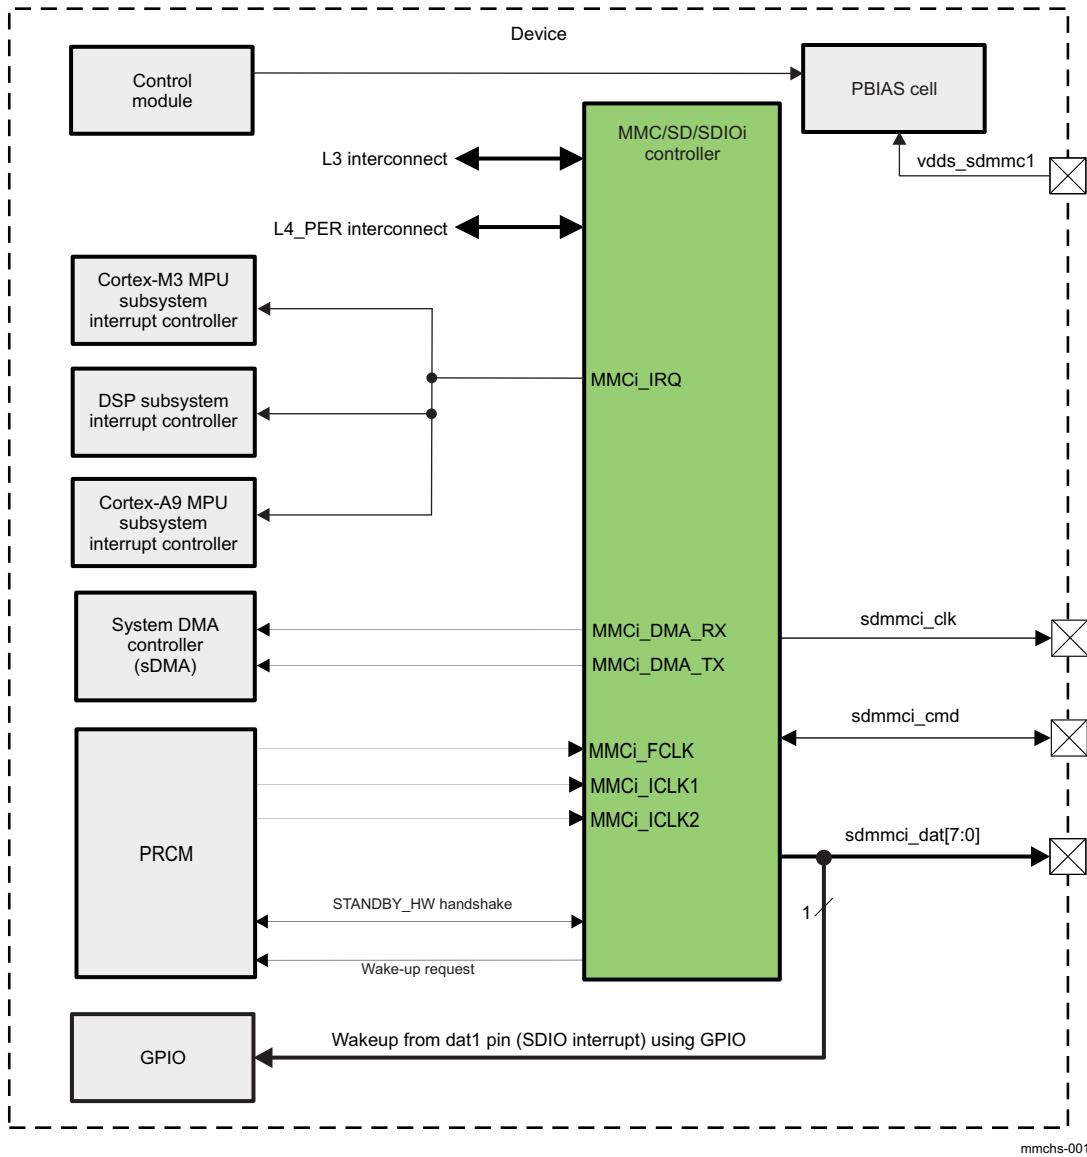

Figure 24-2. MMC/SD/SDIO2 Overview (where i = 2)

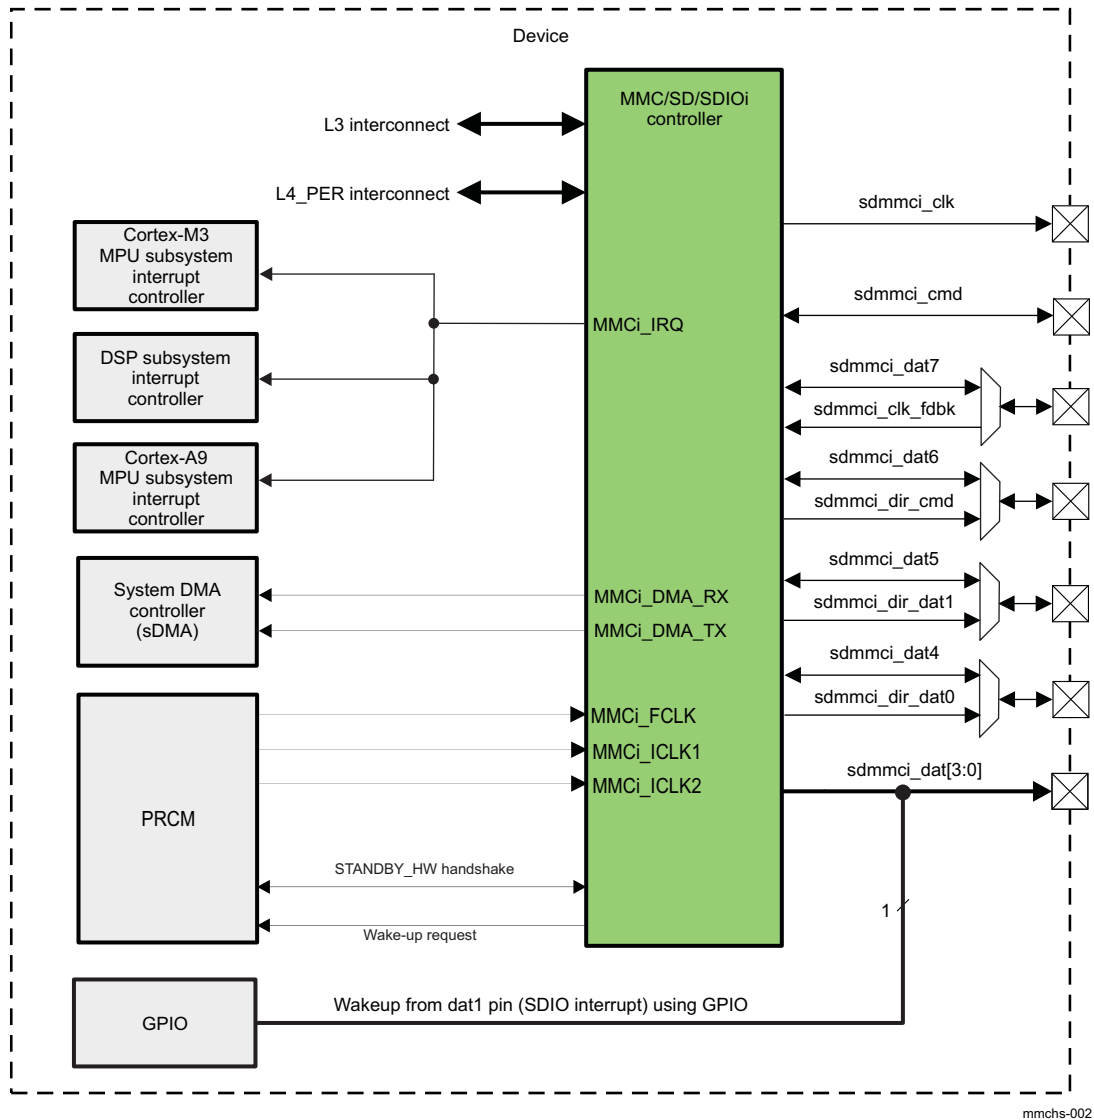

Figure 24-3. MMC/SD/SDIO3 Through MMC/SD/SDIO5 Overview (where i = 3, 4, or 5)

### 24.1.1 MMC/SD/SDIO Features

This section describes the features supplied by the MMC/SD/SDIO module.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the *JC64 MMC/eMMC Standard Specification v4.41*, including high-capacity (size > 2GB) cards HC MMC
- Full compliance with SD command/response sets as defined in the *SD Specifications Part 1 Physical Layer Simplified Specification*, v3.01, including high-capacity SDXC cards up to 2TB
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations, as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.41
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

Main features of the MMC/SD/SDIO host controller:

- Flexible architecture allowing support for new command structure
- Support:
  - 1- or 4-bit transfer mode specifications for SD and SDIO cards
  - 1-, 4-, or 8-bit transfer mode specifications for MMC cards
- Built-in buffer for read or write (up to 2048 bytes in single-buffering, 1024 bytes in double-buffering)
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for interrupt source events
- Two slave DMA channels (one for TX, one for RX)
- Designed for low power
- Programmable clock generation
- Support SDIO read wait and suspend/resume functions
- Support stop at block gap
- Support boot mode operations as specified in the *JEDEC JC 64 MMC/eMMC Standard Specification, v4.41*
- Support dual data rate transfers (DDR mode) as specified in *JEDEC JC64 MMC/eMMC Standard Specification, v4.41*
- Support SDA 2.0 Part A2 programming model

Optional features (depending on module integration):

- Master interface (L3 interconnect)
- One master DMA (32-bit ADMA2), replacing the two slave DMA channels
- Retention mode is supported
- Support SDA 2.0 Part A2 DMA feature (ADMA2)

Supported data rates:

- In MMC mode:
  - Up to 768 Mbps (96 MB/s), 8-bit DDR data transfer, with a clock running at 48 MHz
  - Up to 384 Mbps (48 MB/s), 8-bit SDR data transfer, with a clock running at 48 MHz
- In SD mode:
  - Up to 384 Mbps (48 MB/s), 4-bit DDR data transfer with a clock running at 48 MHz
  - Up to 256 Mbps (32 MB/s), 4-bit SDR data transfer with a clock running at 64 MHz
- In SDIO mode:
  - Up to 192 Mbps (24 MB/s) in high-speed mode, 4-bit data transfer with a clock running at 48 MHz
  - Up to 24 Mbps (3 MB/s) in default speed mode, 1-bit data transfer with a clock running at 24 MHz

Supported clock frequencies:

- MMC mode:
  - Up to 48 MHz in DDR and SDR modes
- SD mode:
  - Up to 48 MHz in DDR mode
  - Up to 64 MHz in SDR mode
- SDIO mode:
  - Up to 48 MHz in SDR mode

Known limitations:

- No built-in hardware support for error correction codes (ECCs). For information about ECC, see the *Multimedia Card System Specification, v4.4*, and the *SD Memory Card Specifications, v3.0*.
- The maximum block size defined in the *SD Memory Card Specifications, v3.0*, which the host driver can read and write to the buffer in the host controller, is 2048 bytes. The host controller supports a

maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in the host controller is considered as a double-buffering with ping-pong management; half of the buffer can be written while the other half is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

- SPI transfers are not supported.
- The module does not support card insertion and removal sensing with pullup resistor on the sdmmc\_i\_dat3 bus line, as specified in the *SD Memory Card Specifications – Part 1 Physical Layer Specification (SD Group, May 2006)*.

The differences between the MMC/SD/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification, v2.00* are:

- The MMC/SD/SDIO host controllers support MMC cards.
- The clock divider in the MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications, v2.0*. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy time-out.
- sDMA and ADMA2 64-bit modes are not supported.
- There is no external LED control.

---

**NOTE:** Only even ratios are supported in DDR mode.

---

[Table 24-1](#) lists the features supported in the 4.41 standard.

**Table 24-1. Standard 4.41 Supported Features**

Feature	Support	Limitation	Comment
Bus width	1-bit mode		x 1, 4, 8 bits
	4-bit mode		
	8-bit mode		
Support density	No hardware limitation for density support	Limitation can come from file system (32GB)	
Simple boot (CMD, alternate boot)	No		OMAP4 ROM code supports the following boot mode:
			In raw mode the booting image can be at one of the four consecutive locations in the main area:
			offset 0x0
			0x20000 (128KB)
			0x40000 (256KB)
			0x60000 (384KB)
	(That is, it supports four boot partitions.)		
Sleep mode	Yes		
Reliable write	Yes		
Secure write protection	Yes		
Hardware reset	No		Use the reset command instead of GPIO if hardware reset is needed.
Secure memory block (RPMB)	Yes		
Partition feature	Yes		
Secure erase	Yes		
1.2 V	Yes		
DDR Interface (bandwidth)	Up to 96MBps in DDR mode – 8-bit		

**Table 24-1. Standard 4.41 Supported Features (continued)**

Feature	Support	Limitation	Comment
High-priority interrupt (read while write)	Yes		
Background operation	Yes		
Enhanced reliable write	Yes		

## 24.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

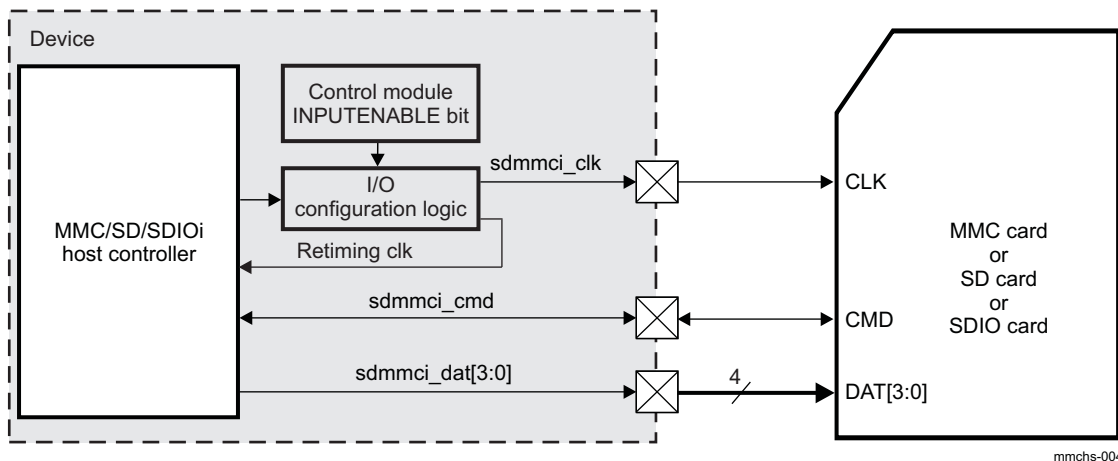

- The MMC/SD/SDIO1 controller integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 V and 3 V), without external transceiver. It is connected to the level 3 (L3) interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers.
- The MMC/SD/SDIO2 controller allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (JC64, for example). The module is connected to the L3 interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers. The second instance also supports an external transceiver and provides direction signals for data and command. Using an external transceiver device precludes 8-bit transfer mode.
- The MMC/SD/SDIO3, MMC/SD/SDIO4, and MMC/SD/SDIO5 controllers allow connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (wireless LAN, for example). The modules are connected to the L4 interconnect and support 1- and 4-bit data transfers.

### 24.2.1 MMC/SD/SDIO Functional Modes

#### 24.2.1.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 24-4 shows the MMC/SD/SDIO<sub>i</sub> host controller (where *i* = 1 through 5) connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 24-4. MMC/SD/SDIO<sub>i</sub> Controller Connected to an MMC, an SD, or an SDIO Card Without External Transceiver (where *i* = 1 through 5)

**NOTE:** MMC/SD/SDIO1 and MMC/SD/SDIO2 support data transfers on 8 bits (and thus handle data on signals sdmmc\_i\_dat[7:0]).

Table 24-2 describes the MMC/SD/SDIO<sub>i</sub> inputs and outputs.

Table 24-2. MMC/SD/SDIO<sub>i</sub> I/O Description Without External Transceiver (where *i* = 1 through 5)

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>
sdmmc_i_clk	O	External clock for MMC/SD/SDIO card <sup>(3)</sup>	0

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

<sup>(2)</sup> hi-Z = High impedance

<sup>(3)</sup> This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

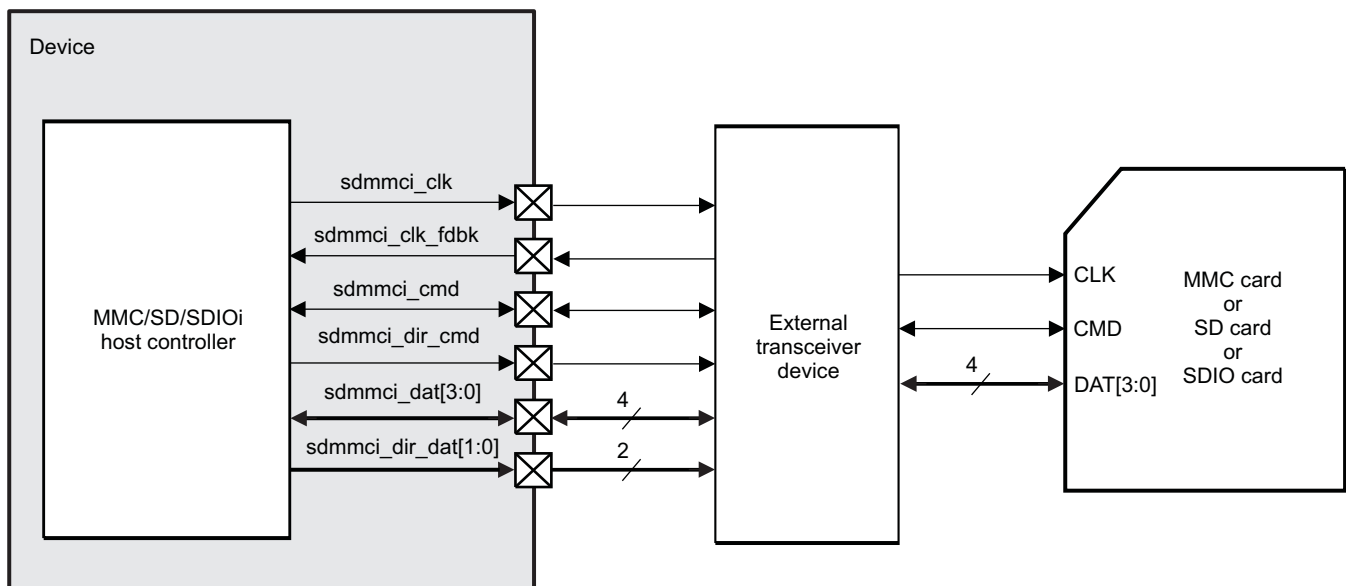

**Table 24-2. MMC/SD/SDIOi I/O Description Without External Transceiver (where i = 1 through 5) (continued)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>
sdmmc_i_cmd	I/O	Command signal	hi-Z <sup>(4)</sup>
sdmmc_i_dat[3:0]	I/O	Data signals	hi-Z <sup>(4)</sup>
sdmmc_i_dat[7:4]	I/O	Data signals (only for modules MMC/SD/SDIO1 and MMC/SD/SDIO2)	hi-Z <sup>(4)</sup>

<sup>(4)</sup> Initialized as input upon reset

### 24.2.1.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device

Figure 24-5 shows the MMC/SD/SDIOi host controller (where i = 2) connected to an MMC, an SD, or an SDIO card and its related external connections.

**Figure 24-5. MMC/SD/SDIOi Controller Connected to an MMC, an SD, or an SDIO Card With External Transceiver (where i = 2)**

mmchs-005

Table 24-3 describes the MMC/SD/SDIOi inputs and outputs.

**Table 24-3. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>
sdmmc_i_clk	O	External clock for MMC/SD/SDIO card	0
sdmmc_i_clk_fdbk	I	Input clock from MMC/SD/SDIO card	0
sdmmc_i_cmd	I/O	Command signal	hi-Z <sup>(3)</sup>
sdmmc_i_dir_cmd	O	Direction control for mmc2_cmd signal when an external transceiver is used (high when transmit, low when receive)	0
sdmmc_i_dat[3:0]	I/O	Data signals	hi-Z <sup>(3)</sup>
sdmmc_i_dir_dat0	O	Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive)	0

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

<sup>(2)</sup> hi-Z = High impedance

<sup>(3)</sup> Initialized as input upon reset

**Table 24-3. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2) (continued)**

Signal Name	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>
sdmmc_dir_dat1	O	Direction control for mmc2_dat1 signal when an external transceiver is used (high when transmit, low when receive)	0

**NOTE:** There is no signal for individually controlling the sdmmc\_dir\_dat2 and sdmmc\_dir\_dat3 direction (sdmmc\_dir\_dat2 and sdmmc\_dir\_dat3 are not delivered). This may limit the use of this interface with the SDIO card requesting the wait feature on the sdmmc\_dir\_dat2 line.

## 24.2.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

**Command:** A command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the sdmmc\_cmd line.

**Response:** A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the sdmmc\_cmd line.

**Data:** Data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the data lines.

**Busy:** The sdmmc\_dat0 signal is maintained low by the card as far as it is programming the data received.

**CRC status:** The CRC result is sent by the card through the sdmmc\_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on sdmmc\_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on sdmmc\_dat0 and starts the data programming procedure.

### 24.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

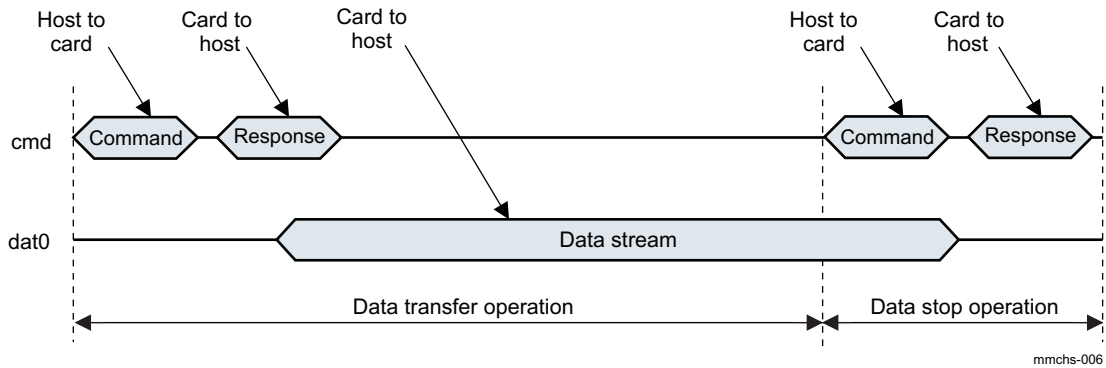

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

Figure 24-6 and Figure 24-7 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the sdmmc\_cmd line.

#### CAUTION

Stream commands are supported only by MMC cards.

**Figure 24-6. Sequential Read Operation (MMC Cards Only)**

**Figure 24-7. Sequential Write Operation (MMC Cards Only)**

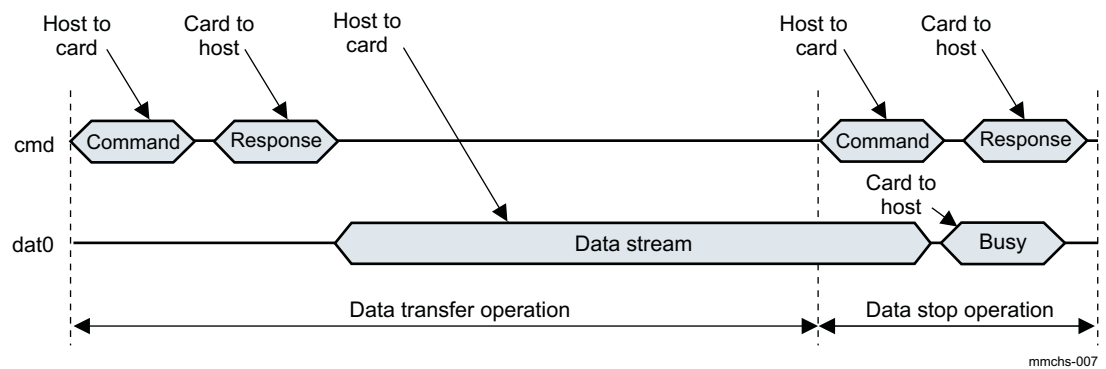

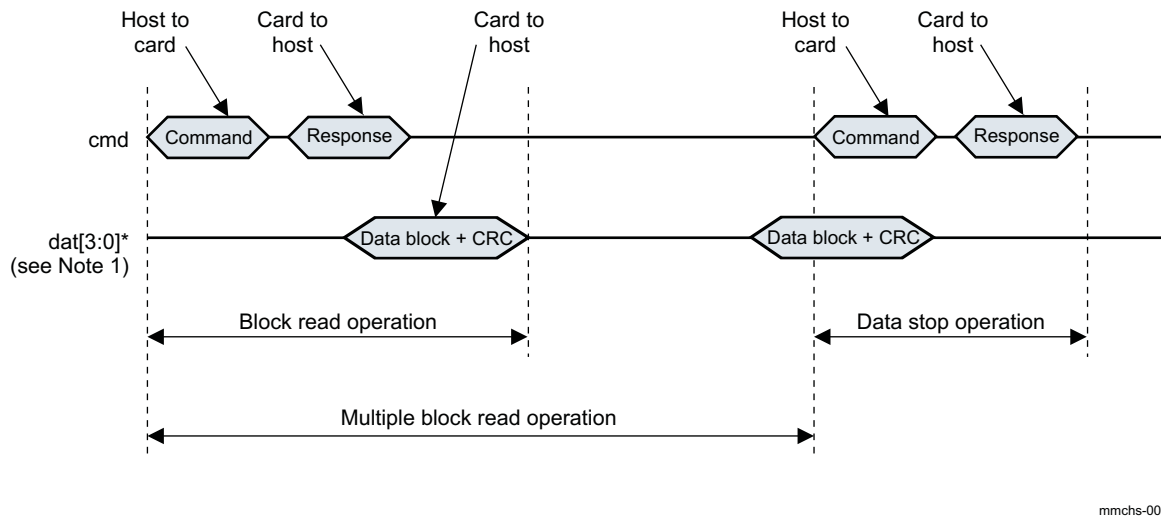

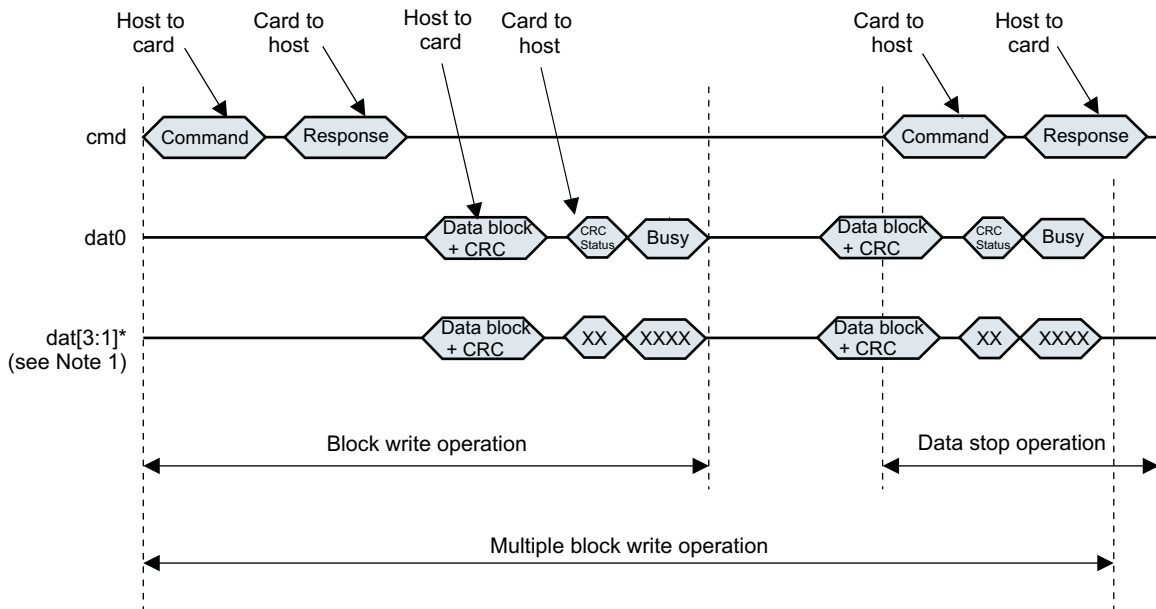

Figure 24-8 and Figure 24-9 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the `sdmmc_cmd` line. These operations are available for all kinds of cards.

**Figure 24-8. Multiple Block Read Operation**

**Figure 24-9. Multiple Block Write Operation With Card Busy Signal**

mmchs-009

**NOTE:**

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. Software must perform a software reset (set the MMCI.MMCHS\_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure sdmmc\_i\_clk is stopped.
3. For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

**24.2.2.2 Data Format**

**Coding Scheme for Command Token**

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 24-10).

**Figure 24-10. Command Token Format**

mmchs-010

**Coding Scheme for Response Token**

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SDIO]) and the content is protected by 7-bit CRC checksum (see [Figure 24-11](#) and [Figure 24-12](#)). Depending on the type of commands sent to the card, the `MMCHS_CMD` register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 24-4](#)). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

**Figure 24-11. Response Token Format (R1, R3, R4, R5, R6, R7)**

**Figure 24-12. Response Token Format (R2)**

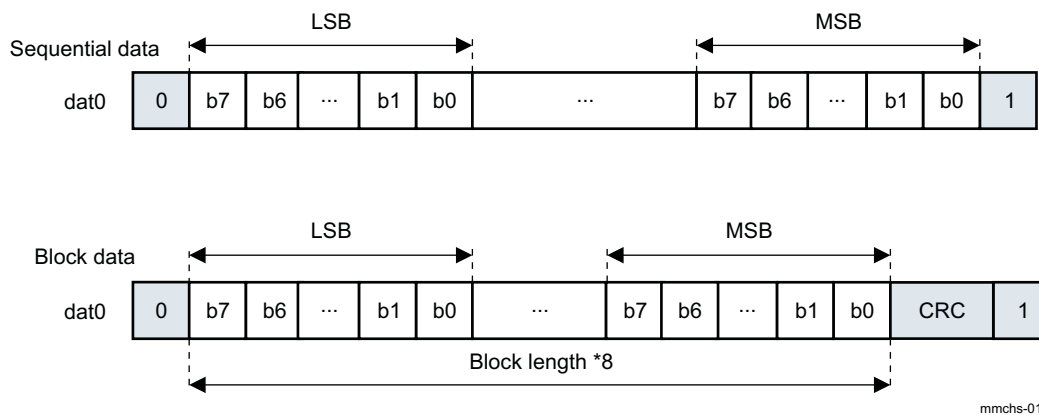

**Table 24-4. Relationship Between Configuration and Name of Response Type**

Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCi.MMCHS_CMD[20] CICE	CRC Check Enable MMCi.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5, R7
11	1	1	R1b, R5b

**Coding Scheme for Data Token**

Data tokens always start with 0 and end with 1 (see Figure 24-13 through Figure 24-15).

**Figure 24-13. Data Token Format for 1-Bit Transfers**

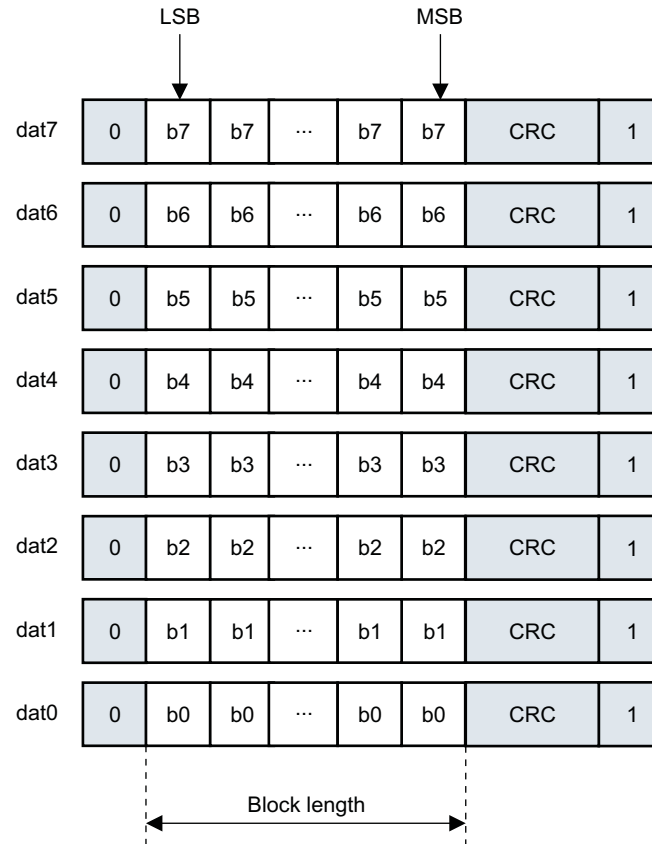

mmchs-013

**Figure 24-14. Data Token Format for 4-Bit Transfers**

### 24.3 MMC/SD/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-16 shows the MMC/SD/SDIO integration.

**Figure 24-16. MMC/SD/SDIO Controllers Integration**

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-5 through Table 24-7 summarize the integration of the module in the device.

**Table 24-5. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
HSMMC1	PD_L3_INIT	L3 L4_PER
HSMMC2	PD_L3_INIT	L3 L4_PER
HSMMC3	PD_L4_PER	L4_PER
HSMMC4	PD_L4_PER	L4_PER
HSMMC5	PD_L4_PER	L4_PER

**Table 24-6. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
HSMMC1	MMC1_FCLK	MMC1_FCLK	PRCM	MMC1 function clock
	MMC1_ICLK2	INIT_L4_ICLK	PRCM	MMC1 interface clock
	MMC1_ICLK1	INIT_L3_ICLK	PRCM	MMC1 interface clock

	MMC2_IRQ	D_IRQ_17	DSP INTC	MMC2 interrupt to DSP
	MMC2_IRQ	MA_IRQ_86	Cortex-A9 INTC	MMC2 interrupt to Cortex-A9
HSMMC3	MMC3_IRQ	MM_IRQ_52	Cortex-M3 INTC	MMC3 interrupt to Cortex-M3
	MMC3_IRQ	MA_IRQ_94	Cortex-A9 INTC	MMC3 interrupt to Cortex-A9
HSMMC4	MMC4_IRQ	MM_IRQ_53	Cortex-M3 INTC	MMC4 interrupt to Cortex-M3
	MMC4_IRQ	MA_IRQ_96	Cortex-A9 INTC	MMC4 interrupt to Cortex-A9
HSMMC5	MMC5_IRQ	MM_IRQ_54	Cortex-M3 INTC	MMC5 interrupt to Cortex-M3
	MMC5_IRQ	MA_IRQ_59	Cortex-A9 INTC	MMC5 interrupt to Cortex-A9
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
HSMMC1	MMC1_DMA_TX	S_DMA_60	sDMA	MMC1 DMA TX
	MMC1_DMA_RX	S_DMA_61	sDMA	MMC1 DMA RX
HSMMC2	MMC2_DMA_TX	S_DMA_46	sDMA	MMC2 DMA TX
	MMC2_DMA_RX	S_DMA_47	sDMA	MMC2 DMA RX
HSMMC3	MMC3_DMA_TX	S_DMA_76	sDMA	MMC3 DMA TX
	MMC3_DMA_RX	S_DMA_77	sDMA	MMC3 DMA RX
HSMMC4	MMC4_DMA_TX	S_DMA_56	sDMA	MMC4 DMA TX
	MMC4_DMA_RX	S_DMA_57	sDMA	MMC4 DMA RX
HSMMC5	MMC5_DMA_TX	S_DMA_58	sDMA	MMC5 DMA TX
	MMC5_DMA_RX	S_DMA_59	sDMA	MMC5 DMA RX

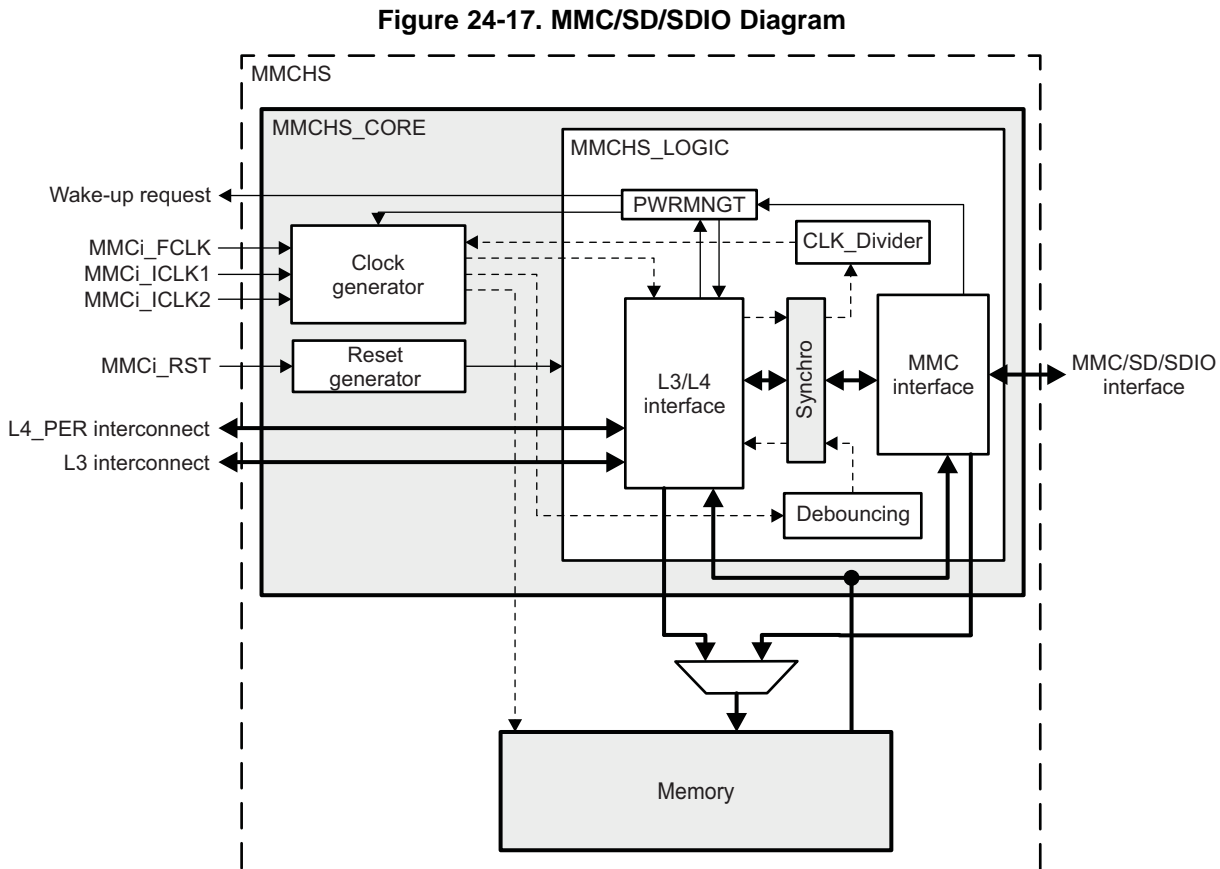

**NOTE:**

- For a description of the interrupt source, see [Section 24.4.4, Interrupt Requests](#).
- For a description of the DMA source, see [Section 24.4.5, DMA Modes](#).

## 24.4 MMC/SD/SDIO Functional Description

### 24.4.1 Block Diagram

Figure 24-17 is a block diagram of the MMC/SD/SDIOi host controller.

mmchs-017

### 24.4.2 Resets

#### 24.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see [Table 24-6](#) for more information about reset signals).

The MMCHS.MMCHS\_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

**NOTE:** The functional clock (MMCi\_FCLK) and interface clock (MMCi\_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCi\_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

#### 24.4.2.2 Software Reset

The module is reinitialized by software through the MMCHS.MMCHS\_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal (MMCi\_RST), with the following exceptions:

- Debounce logic

- MMCi.MMCHS\_PSTATE, MMCi.MMCHS\_CAPA, and MMCi.MMCHS\_CUR\_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCi.MMCHS\_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCi.MMCHS\_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS\_SYSCTL[26] SRD
- MMCi.MMCHS\_SYSCTL[25] SRC

These two reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS\_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCi.MMCHS\_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

### 24.4.3 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the handshake protocol of the PRCM module.

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor the state of the sdmmc\_i\_dat1 input pin through a different GPIO line for each MMC/SD/SDIO interface (for more information, see [Section 25.1](#), *GPIO Overview*, in [Chapter 25](#), *GPIO*).

#### Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS\_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from an SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters into LOW-POWER state (MMCi\_ICLK clock autogated) even if the MMCi.MMCHS\_SYSCONFIG[0] AUTOIDLE bit is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

#### Idle Mode

The MMCi\_ICLK and MMCi\_FCLK clocks provided to the MMC/SD/SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCi.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager

request unconditionally.

- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCi\_ICLK and MMCi\_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS\_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

### Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the sdmmc\_i\_dat1 signal.

As long as the MMC/SD/SDIOi controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM module.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

### Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- The MMCi.MMCHS\_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1.
- The MMCi.MMCHS\_HCTL[24] IWE bit is set to 0x1.
- The MMCi.MMCHS\_IE[8] CIRQ\_ENABLE bit is set to 0x1.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 24-8 lists the supported cases in smart-idle mode.

**Table 24-8. Smart-Idle Mode and Wake-Up Capabilities**

Mode	MMCi_ICLK Clock	MMCi_FCLK Clock	Wake-Up Event
Card interrupt	May be switched off <sup>(1)</sup>	May be switched off <sup>(1)</sup>	The module sends an asynchronous wake-up request when a card interrupt on sdmmc_i_dat1 signal is detected.

<sup>(1)</sup> The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS\_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

### Transition From Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM module deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCI.MMCHS\_STAT register. The MMC/SD/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCI.MMCHS\_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCI.MMCHS\_HCTL and MMCI.MMCHS\_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCI.MMCHS\_STAT is updated in the CIRQ bit with the event that caused the wake-up when the MMCI.MMCHS\_IE[8] CIRQ\_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCI.MMCHS\_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

### Force-Idle Mode

Force-idle mode is enabled when the MMCI.MMCHS\_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM module. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCI.MMCHS\_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCI\_ICLK and MMCI\_FCLK can be switched off.

#### CAUTION

In force-idle mode, an idle request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCI\_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

### Local Power Management

Table 24-9 describes the power-management features available for the MMC/SD/SDIOi modules.

**NOTE:** For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

**Table 24-9. Local Power-Management Features**

Feature	Registers	Description
Clock auto gating	MMCHS_SYSCONFIG[0] AUTOIDLE	This bit allows a local power optimization inside the module by gating the MMCI_ICLK clock upon the interface activity, or gating the MMCI_FCLK clock upon the internal activity.

**Table 24-9. Local Power-Management Features (continued)**

Feature	Registers	Description
Slave idle modes	MMCHS_SYSCONFIG[3:4] SIDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	MMCHS_SYSCONFIG[8:9] CLOCKACTIVITY	For configuration details, see <a href="#">Table 24-10</a> .
Master standby modes	MMCHS_SYSCONFIG[12:13] STANDBYMODE	Force-idle, no-idle, and smart-idle modes are available.
Global wake-up enable	MMCHS_SYSCONFIG[2] ENAWAKEUP	This bit enables the wake-up feature at the module level.
Wake-up sources enable	MMCHS_HCTL register	This register holds one active-high enable bit per event source that is able to generate a wake-up signal.

**Table 24-10. Clock Activity Settings**

CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	MMCi_ICLK	MMCi_FCLK		
00	OFF	OFF	None	Card interrupt
10	OFF	ON	None	
01	ON	OFF	None	
11	ON	ON	All	

**CAUTION**

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**24.4.4 Interrupt Requests**

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS\_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS\_IE register enable or disable the automatic update of the MMCi.MMCHS\_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS\_ISE register enable or disable the transmission of an interrupt request on the interrupt line MMCi\_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem INTC) on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS\_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS\_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS\_STAT register. If a mask is later applied on the interrupt in the MMCi.MMCHS\_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS\_STAT register and the corresponding mask is removed from the MMCi.MMCHS\_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS\_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

### CAUTION

If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS\_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS\_STAT register or transmitting an interrupt request.

Table 24-11 lists the event flags, and their mask, that can cause module interrupts.

**Table 24-11. Events**

Event Flag	Event Mask	Map to	Description
MMCHS_STAT[29] BADA	MMCHS_IE[29] BADA_ENABLE	MMCi_IRQ	<p>Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed:</p> <p>This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0).</p> <p>This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[10] BWE = 0).</p>
MMCHS_STAT[28] CERR	MMCHS_IE[28] CERR_ENABLE	MMCi_IRQ	<p>Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.</p>
MMCHS_STAT[25] ADMAE	MMCHS_IE[25] ADMAE_ENABLE	MMCi_IRQ	<p>ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.</p>
MMCHS_STAT[24] ACE	MMCHS_IE[24] ACE_ENABLE	MMCi_IRQ	<p>Auto CMD12 error. This bit is set automatically when one bit in the auto CMD12 error status register changes from 0 to 1.</p>
MMCHS_STAT[22] DEB	MMCHS_IE[22] DEB_ENABLE	MMCi_IRQ	<p>Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.</p>
MMCHS_STAT[21] DCRC	MMCHS_IE[21] DCRC_ENABLE	MMCi_IRQ	<p>Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.</p>
MMCHS_STAT[20] DTO	MMCHS_IE[20] DTO_ENABLE	MMCi_IRQ	<p>Data time-out error. This bit is set automatically according to the following conditions:</p> <ul style="list-style-type: none"> <li>– Busy time-out for R1b, R5b response type</li> <li>– Busy time-out after write CRC status</li> <li>– Write CRC status time-out</li> <li>– Read data time-out</li> </ul>
MMCHS_STAT[19] CIE	MMCHS_IE[19] CIE_ENABLE	MMCi_IRQ	<p>Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.</p>

**Table 24-11. Events (continued)**

Event Flag	Event Mask	Map to	Description
<a href="#">MMCHS_STAT[18]</a> CEB	<a href="#">MMCHS_IE[18]</a> CEB_ENABLE	MMCi_IRQ	Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.
<a href="#">MMCHS_STAT[17]</a> CCRC	<a href="#">MMCHS_IE[17]</a> CCRC_ENABLE	MMCi_IRQ	Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the <a href="#">MMCHS_CMD[19]</a> CCCE bit.
<a href="#">MMCHS_STAT[16]</a> CTO	<a href="#">MMCHS_IE[16]</a> CTO_ENABLE	MMCi_IRQ	Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles.
<a href="#">MMCHS_STAT[15]</a> ERR1	<a href="#">MMCHS_IE[15]</a> ERR1_ENABLE	MMCi_IRQ	Error interrupt. If any of the bits in the error interrupt status register ( <a href="#">MMCHS_STAT[24:15]</a> ) are set, this bit is set to 1.
<a href="#">MMCHS_STAT[10]</a> BSR	<a href="#">MMCHS_IE[10]</a> BSR_ENABLE	MMCi_IRQ	Boot status received interrupt. This bit is set automatically when the <a href="#">MMCHS_CON[18]</a> BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card.
<a href="#">MMCHS_STAT[8]</a> CIRQ	<a href="#">MMCHS_IE[8]</a> CIRQ_ENABLE	MMCi_IRQ	Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end.
<a href="#">MMCHS_STAT[5]</a> BRR	<a href="#">MMCHS_IE[5]</a> BRR_ENABLE	MMCi_IRQ	Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the <a href="#">MMCHS_BLK[10:0]</a> BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH needs to empty the buffer by reading it.
<a href="#">MMCHS_STAT[4]</a> BWR	<a href="#">MMCHS_IE[4]</a> BWR_ENABLE	MMCi_IRQ	Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the <a href="#">MMCHS_BLK[10:0]</a> BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer.
<a href="#">MMCHS_STAT[3]</a> DMA	<a href="#">MMCHS_IE[3]</a> DMA_ENABLE	MMCi_IRQ	DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes.
<a href="#">MMCHS_STAT[2]</a> BGE	<a href="#">MMCHS_IE[2]</a> BGE_ENABLE	MMCi_IRQ	Block gap event. When a stop at the block gap is requested ( <a href="#">MMCHS_HCTL[16]</a> SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.
<a href="#">MMCHS_STAT[1]</a> TC	<a href="#">MMCHS_IE[1]</a> TC_ENABLE	MMCi_IRQ	Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request ( <a href="#">MMCHS_HCTL[16]</a> SBGR).  – In read mode: This bit is automatically set on completion of a read transfer ( <a href="#">MMCHS_PSTATE[9]</a> RTA).

**Table 24-11. Events (continued)**

Event Flag	Event Mask	Map to	Description
<a href="#">MMCHS_STAT[0] CC</a>	<a href="#">MMCHS_IE[0] CC_ENABLE</a>	MMCi_IRQ	<p>– In write mode: This bit is automatically set on completion of the DAT line use (<a href="#">MMCHS_PSTATE[2] DLA</a>).</p> <p>Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (<a href="#">MMCHS_PSTATE[0] CMDI</a>). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (<a href="#">MMCHS_STAT[16] CTO</a>) has higher priority than command complete (<a href="#">MMCHS_STAT[0] CC</a>). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.</p>

---

**NOTE:** To send an interrupt request to the MMCi\_IRQ line, the mask/unmask bit must be set in the MMCi.[MMCHS\\_IE](#) and MMCi.[MMCHS\\_ISE](#) registers.

---

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

#### 24.4.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.[MMCHS\\_IE](#) register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.[MMCHS\\_STAT](#) register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.[MMCHS\\_STAT](#) register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

---

**NOTE:** In the MMCi.[MMCHS\\_STAT](#) register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.[MMCHS\\_STAT\[8\]](#) CIRQ status bit must be masked by disabling the MMCi.[MMCHS\\_IE\[8\]](#) CIRQ\_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.[MMCHS\\_STAT\[15\]](#) ERRI bit is automatically cleared when all status bits in the MMCi.[MMCHS\\_STAT\[31:16\]](#) bit field are cleared.

---

#### 24.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.[MMCHS\\_ISE](#) register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.[MMCHS\\_STAT](#) register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.[MMCHS\\_STAT](#) register clears the interrupt status and does not affect the interrupt line state.

---

**NOTE:** Refer to the previous note concerning clearing of the CIRQ and ERRI bits.

---

### 24.4.5 DMA Modes

Two DMA managements can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode

DMA master mode is selected by setting the [MMCHS\\_CON\[20\] DMA\\_MNS](#) bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3 master interface, which supports burst accesses to maximize throughput.

---

**NOTE:** This mode is supported only by modules connected to the L3 interconnect. See [Section 24.1, MMC/SD/SDIO Overview](#), for more information and/or check the value of the [MMCHS\\_HL\\_HWINFO\[0\] MADMA\\_EN](#) bit.

This mode is available for modules MMC1 and MMC2.

---

- DMA slave mode

DMA slave mode is selected by setting the [MMCHS\\_CON\[20\] DMA\\_MNS](#) bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi\_DMA\_TX and MMcI\_DMA\_RX).

---

**NOTE:** This mode is the only mode supported by modules that are not connected to the L3 interconnect (regardless of the value of the [MMCHS\\_CON\[20\] DMA\\_MNS](#) bit). See [Section 24.1, MMC/SD/SDIO Overview](#), for more information and/or to check the value of the [MMCHS\\_HL\\_HWINFO\[0\] MADMA\\_EN](#) bit.

This mode is available for all MMC modules.

---

#### 24.4.5.1 Master DMA Operations

The MMC/SD/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the [MMCHS\\_ADMASAL](#) register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

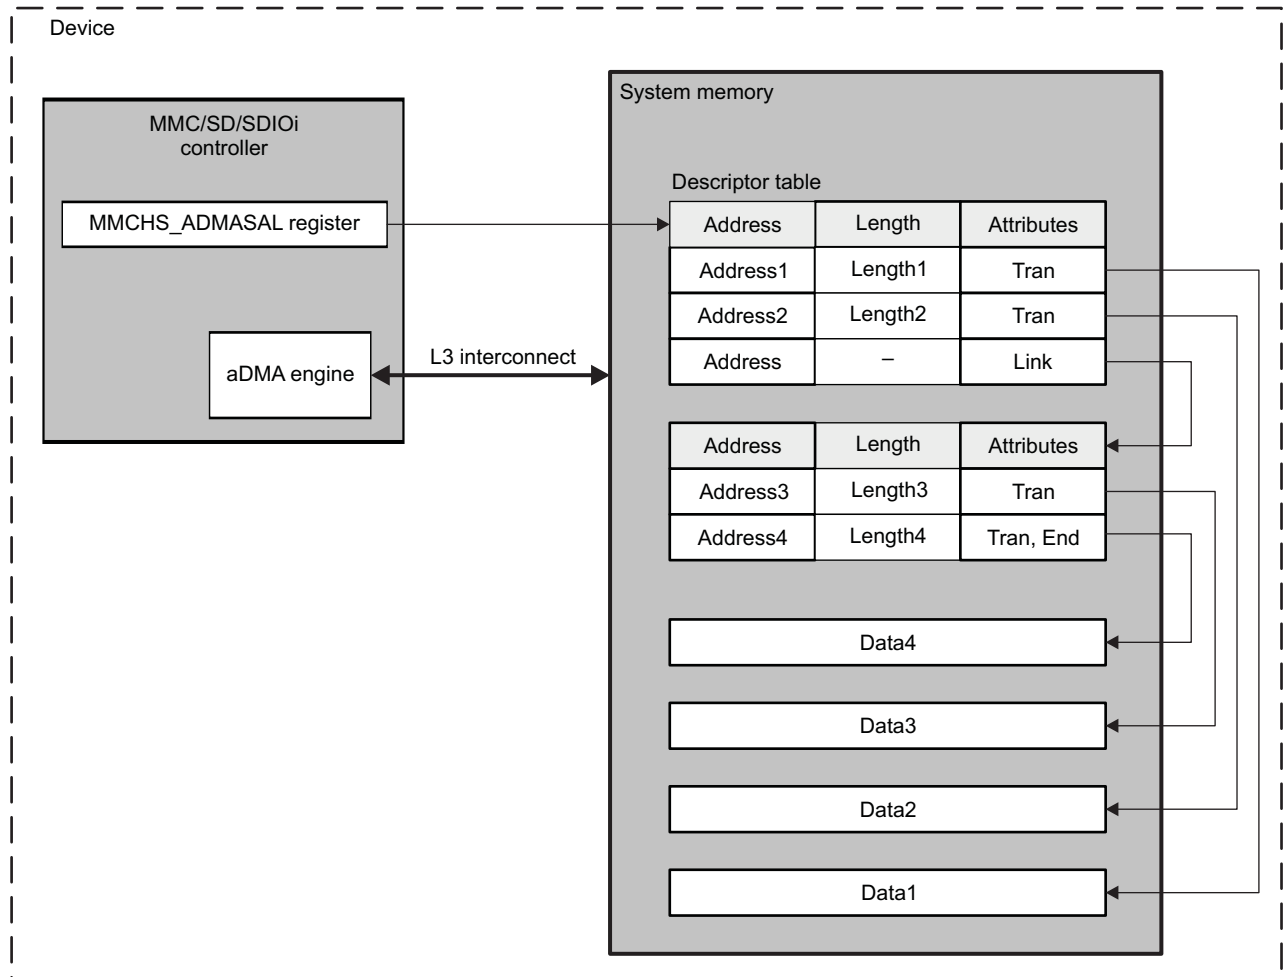

---

**NOTE:** This mode is supported only by modules connected to the L3 interconnect. See [Section 24.1, MMC/SD/SDIO Overview](#), for more information and/or to check the value of the [MMCHS\\_HL\\_HWINFO\[0\] MADMA\\_EN](#) bit.

---

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in [Figure 24-18](#). In this case the [MMCHS\\_ADMASAL](#) register is used as the program address pointer

Figure 24-18. ADMA Block Diagram Overview

mmchs-018

24.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the L3 master interface, and requires two 32-bit accesses to memory.

Table 24-12 shows the structure of a descriptor line.

Table 24-12. Descriptor Line Overview

Address Field		Length		Reserved		Attributes					
63	32	31	16	15	6	5	4	3	2	1	0
32-bit Address		16-bit Length		0x0		Act2	Act1	0	Int	Ent	Valid

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 24-13 describes the available actions of a descriptor line.

**Table 24-13. Available Actions of a Descriptor Line**

Act2	Act1	Symbol	Comment	Operation
0	0	Nop	No operation	Do not execute the current line and go to the next line.
0	1	Rsv	Reserved	Reserved action. Behaves the same as the Nop command.
1	0	Tran	Transfer data	Transfer data of one descriptor line.
1	1	Link	Link descriptor	Link to another descriptor.

Table 24-14 describes the additional parameters of a descriptor line.

**Table 24-14. Additional Parameters of a Descriptor Line**

Bit	Description
Valid	Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways.
End	End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete.
Int	Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete.

#### 24.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

##### 24.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64KB.
- Total length = Length<sub>1</sub> + Length<sub>2</sub> + Length<sub>3</sub> + ... + Length<sub>n</sub> must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the `MMCHS_BLK[31:16]` NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (the `MMCHS_CMD[1]` BCE bit) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

---

**NOTE:** The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active (`MMCHS_PSTATE[9]` RTA), write transfer active (`MMCHS_PSTATE[8]` WTA), and DAT line active (`MMCHS_PSTATE[2]` DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

---

##### 24.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap-request (the `MMCHS_HCTL[16]` SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the `MMCHS_STAT[2]` BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

24.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the MMCHS\_ADMAES[1:0] AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If ADMA stopped at ST\_FDS state, the ADMA system address register (MMCHS\_ADMASAL) points to the erroneous descriptor line.
- If ADMA stopped at ST\_TFR or ST\_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

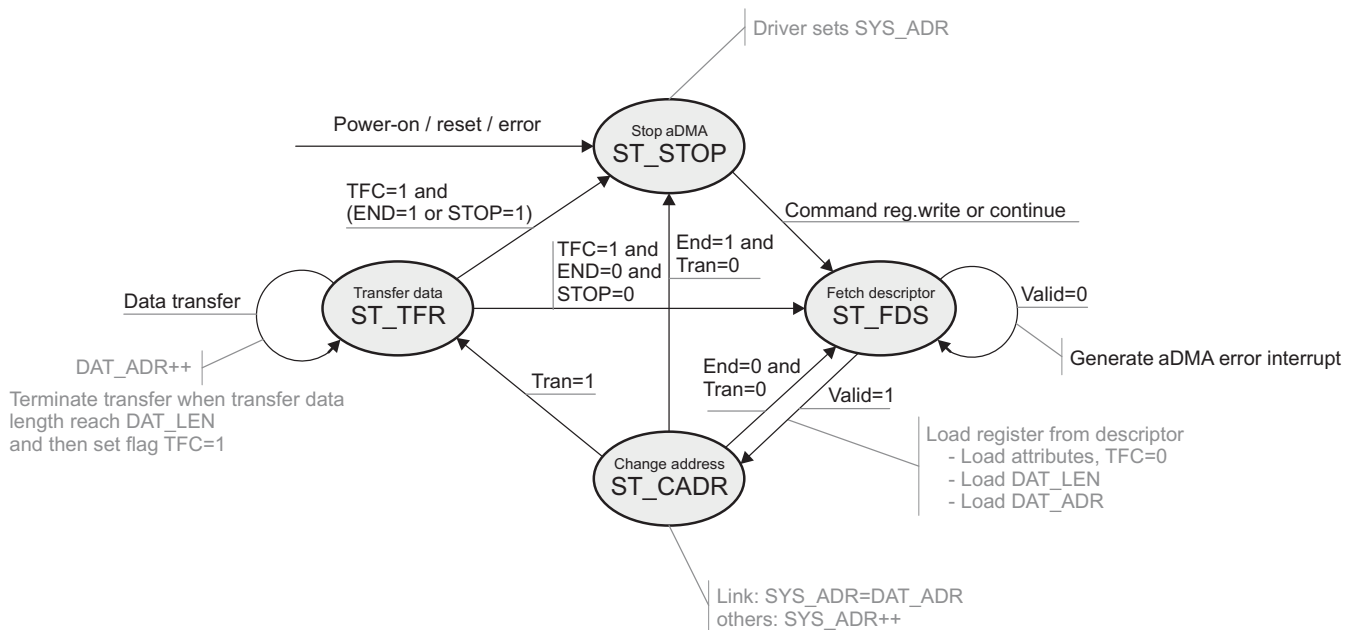

24.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the MMCHS\_ADMASAL register.

**NOTE:** Software must write the base address of the descriptor table in the MMCHS\_ADMASAL register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see Section 24.4.5.1.1, Descriptor Table Description) and an FSM, as shown in Figure 24-19.

Figure 24-19. ADMA Finite State-Machine

mmchs-019

Table 24-15 describes each state of the ADMA FSM.

Table 24-15. ADMA2 States Description

State Name	Operation
ST_FDS (fetch descriptor)	ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to the ST_CADR state.
ST_CADR (change address)	Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. <b>NOTE:</b> ADMA2 does not stop at this state if some errors occur.

**Table 24-15. ADMA2 States Description (continued)**

State Name	Operation
ST_TFR (transfer data)	Data transfer of one descriptor line is executed between system memory and the SD card: <ul style="list-style-type: none"> <li>• If data transfer continues (End = 0) go to ST_FDS state.</li> <li>• If data transfer completes, go to ST_STOP state.</li> </ul>
ST_STOP (stop DMA)	ADMA2 stays in this state in the following cases: <ul style="list-style-type: none"> <li>• After power on reset (POR) or software reset</li> <li>• All descriptor data transfers are complete.</li> </ul> If a new ADMA operation is stated by writing the command register, go to ST_FDS state.

Table 24-16 gives the description of each symbol used in the ADMA FSM state-machine (see Figure 24-19).

**Table 24-16. ADMA FSM Symbol Definition**

Symbol	Definition
SYS_ADR	ADMA system address register
SYS_ADR++	Point to next descriptor line
DAT_ADR	Data address register (internal)
DAT_LEN	Data length register (internal)
TFC	Transfer complete flag (internal)
STOP	Stop-at-block-gap request

#### 24.4.5.2 Slave DMA Operations

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

**NOTE:** This mode is implied by modules that are not connected to the L3 interconnect (regardless of the value of the `MMCHS_CON[20]` DMA\_MNS bit). See Section 24.4.5.1, *Master DMA Operations*, for more information and/or to check the value of the `MMCHS_HL_HWINFO[0]` MADMA\_EN bit.

The DMA request is issued if the following conditions are met:

- The `MMCi.MMCHS_CMD[0]` DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the `sdmmc_i_cmd` line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

##### 24.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal `MMCi_DMA_RX` is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` BLEN bit field.

`MMCi_DMA_RX` is deasserted to its inactive level when the sDMA reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN field block size.

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of sDMA read is  $\text{Integer}(\text{BLEN}/4) + 1$ .

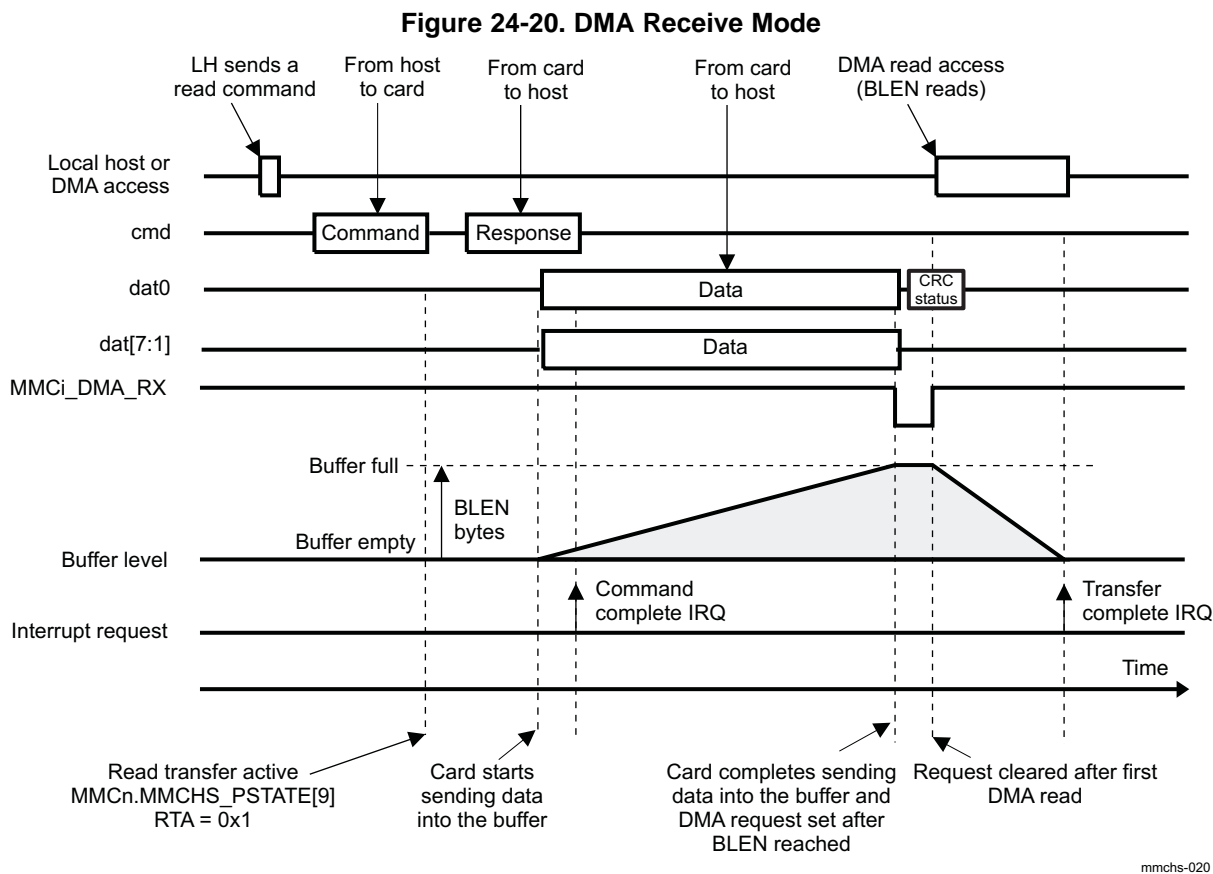

The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the `sdmmc_i_clk` clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-20 shows DMA receive mode.

#### 24.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal `MMCi_DMA_TX` is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` BLEN bit field.

`MMCi_DMA_TX` is deasserted to its inactive level when the sDMA writes one word to the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN field block size.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of sDMA reads is  $\text{Integer}(\text{BLEN}/4) + 1$ ) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-21 shows DMA transmit mode.

**Figure 24-21. DMA Transmit Mode**

### 24.4.6 Mode Selection

The MMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

### 24.4.7 Buffer Management

#### 24.4.7.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, prefetch buffer, and post-write buffer is the 32-bit register `MMCi.MMCHS_DATA` register. A write access to the `MMCi.MMCHS_DATA` register followed by a read access from the `MMCi.MMCHS_DATA` register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the `MMCi.MMCHS_DATA` register and the data of the read access to the `MMCi.MMCHS_DATA` register are different.

The number of 32-bit accesses to the `MMCi.MMCHS_DATA` register that are needed to read (or write) a data block with a size of the `MMCi.MMCHS_BLK[10:0]` `BLEN` bit field equals the rounded up result of `BLEN` divided by 4.

The maximum block size supported by the host controller is hard-coded in the `MMCi.MMCHS_CAPA[17:16]` `MBL` bit field and cannot be changed.

A read access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer read-enable status is set to 1 (the `MMCi.MMCHS_PSTATE[11]` `BRE` bit); otherwise, a bad access (the `MMCi.MMCHS_STAT[29]` `BADA` bit) is signaled.

A write access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer write-enable status is set to 1 (the `MMCi.MMCHS_PSTATE[10]` `BWE` bit); otherwise, a bad access (the `MMCi.MMCHS_STAT[29]` `BADA` bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to `MEM_SIZE/2` (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The MMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When `BLEN` is less than or equal to `0x200` (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of `BLEN` (that is, 32 bits × `BLEN` divided by 4). No more than this total size of  $2 \times 32 \text{ bits} \times \text{BLEN} \text{ divided by } 4$  can be used.

#### CAUTION

The `MMCi.MMCHS_CMD[4]` `DDIR` bit must be configured before a transfer to indicate the direction of the transfer.

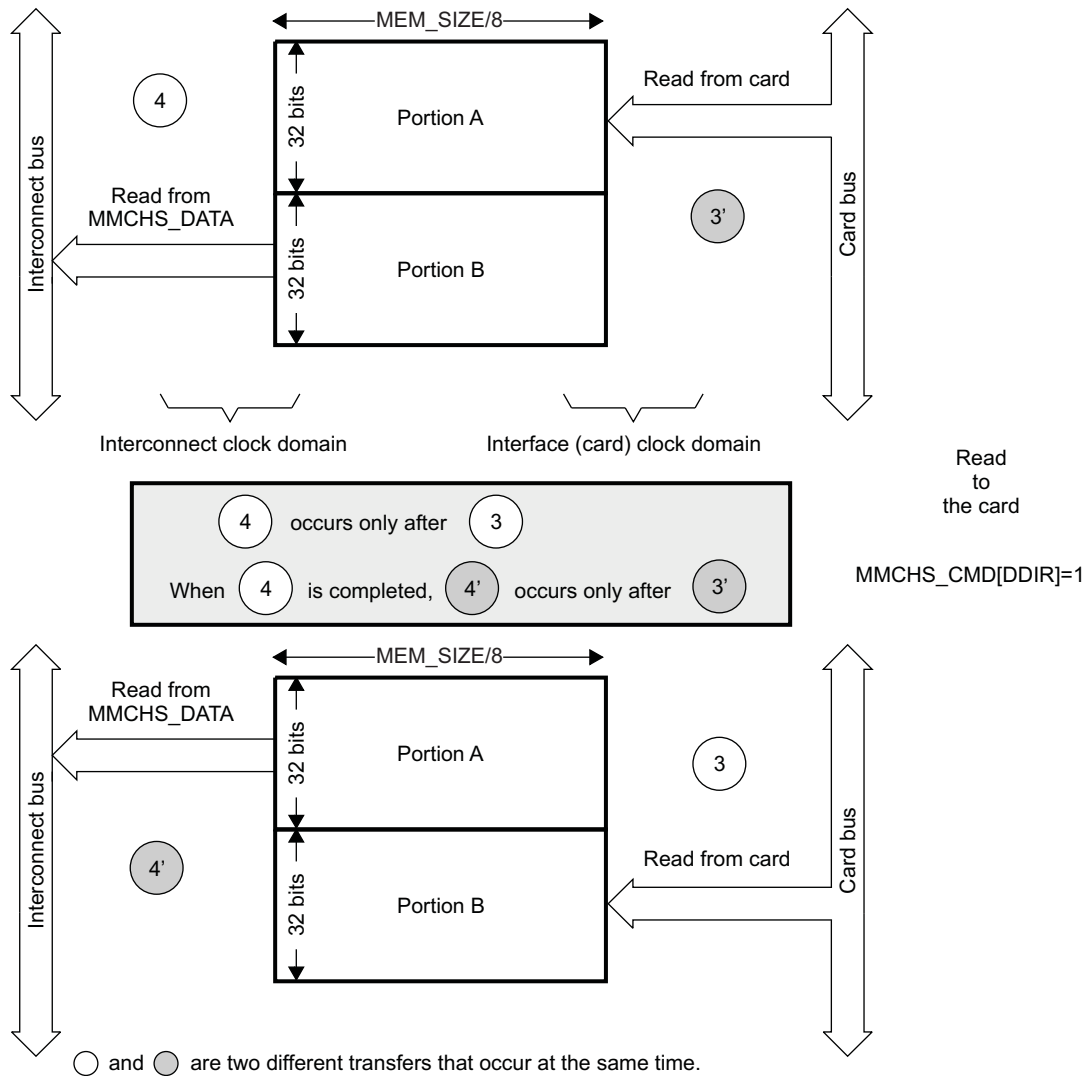

[Figure 24-22](#) and [Figure 24-23](#) show the buffer management for a write and for a read, respectively.

**Figure 24-22. Buffer Management for a Write**

mmchs-022

Figure 24-23. Buffer Management for a Read

- When the size of the data block to transfer is larger than  $MEM\_SIZE/2$ , only one data transfer can occur at a time from one data bus to the other data bus. The MMC/SD/SDIOi host controller uses the entire data buffer as a single portion. In this mode, a bad access (the MMCi.MMCHS\_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

24.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 24-17).

**NOTE:** Double-buffering is always the buffer management for larger memory depth.

Table 24-17. Memory Size, BLEN, and Buffer Relationship

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Maximum block length supported	512	1024

**Table 24-17. Memory Size, BLEN, and Buffer Relationship (continued)**

Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes)	512	1024
Double-buffering for maximum block length	N/A	BLEN<=512
Single-buffering for block length	BLEN<=512	512<BLEN<=1024

**NOTE:** For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS\_CMD[3] DDIR bit is 0) and halted on read MMC transfers (the MMCHS\_CMD[3] DDIR bit is 1).

#### 24.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
  - MMCi.MMCHS\_STAT[29] BADA: Bad access to data space
  - MMCi.MMCHS\_STAT[5] BRR: Buffer read ready
  - MMCi.MMCHS\_STAT[4] BWR: Buffer write ready
- Status registers:
  - MMCi.MMCHS\_PSTATE[11] BRE: Buffer read enable
  - MMCi.MMCHS\_PSTATE[10] BWE: Buffer write enable

#### 24.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

##### 24.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

##### 24.4.8.2 Different Types of Responses

Different types of responses are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

Table 24-18 describes how the MMC, SD, and SDIO responses are stored in the MMCHS\_RSPxx registers.

**Table 24-18. MMC, SD, SDIO Responses in the MMCHS\_RSPxx Registers**

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6, R7	RESP[39:8] <sup>(1)</sup>	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] <sup>(1)</sup>	MMCHS_RSP76[31:0]
R2	RESP[127:0] <sup>(1)</sup>	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

<sup>(1)</sup> RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS\_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS\_RSP76[31:0] register because the host controller may have a multiple block data DAT line transfer executing concurrently with a command. This lets the host controller avoid overwriting the Auto CMD12 response with the command response stored in the MMCHS\_RSP10 register, and vice versa.

#### 24.4.9 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see [Table 24-19](#) and the register description.

**Table 24-19. CC and TC Values Upon Error Detected**

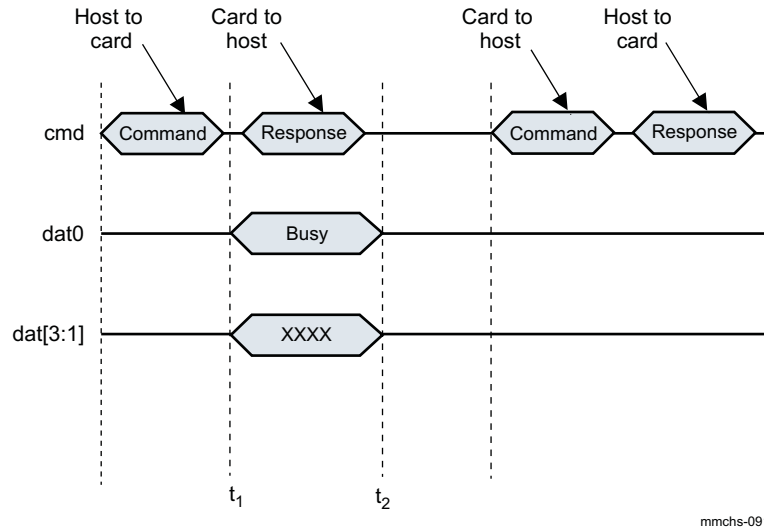

Error Hold in MMCi.MMCHS_STAT	CC	TC	Comments
29 BADA			No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.
21 DCRC		1	TC is set upon DCRC.
20 DTO			DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO.
19 CIE	1		CC is set upon CIE.
18 CEB	1		CC is set upon CEB.
17 CCRC	1		CC can be set upon CCRC. See CTO comment.
16 CTO			CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears.

A MMCHS\_STAT[21] DCRC event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

##### 24.4.9.1 Busy Time-Out for R1b, R5b Response Type

[Figure 24-24](#) shows the DCRC event condition asserted when there is busy time-out for Rb1, R5b response.

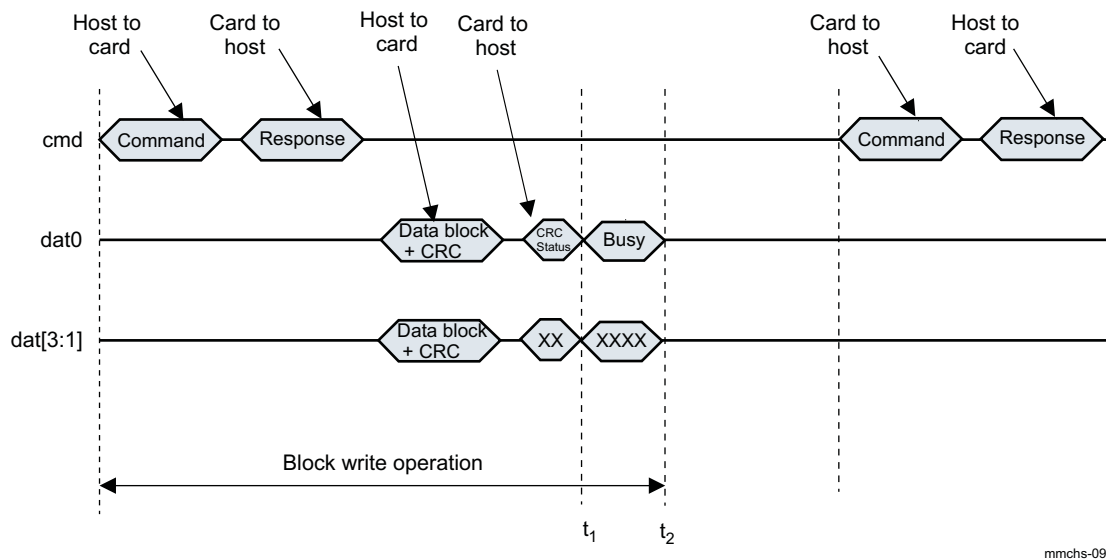

**Figure 24-24. Busy Time-Out for R1b, R5b Response Type**

$t_1$  – Data time-out counter is loaded and starts after R1b, R5b response type.

$t_2$  – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

#### 24.4.9.2 Busy Time-Out After Write CRC Status

Figure 24-25 shows the DCRC event condition asserted when there is busy time-out after write CRC status.

**Figure 24-25. Busy Time-Out After Write CRC Status**

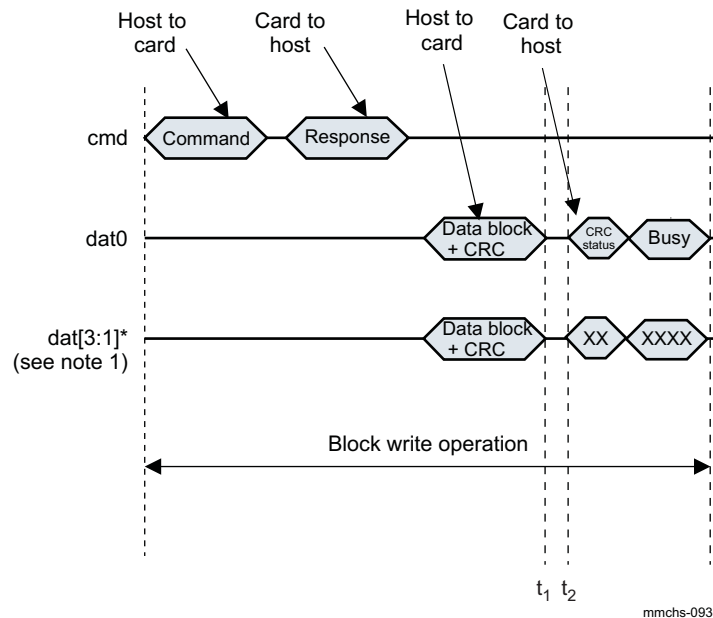

$t_1$  – Data time-out counter is loaded and starts after CRC status.

$t_2$  – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

#### 24.4.9.3 Write CRC Status Time-Out

Figure 24-26 shows the DCRC event condition asserted when there is write CRC status time-out.

Figure 24-26. Write CRC Status Time-Out

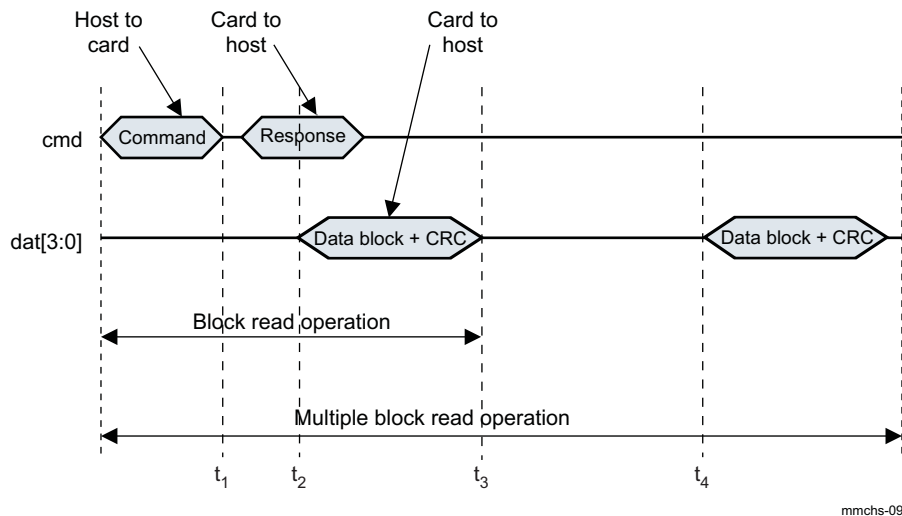

$t_1$  – Data time-out counter is loaded and starts after data block + CRC.

$t_2$  – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

#### 24.4.9.4 Read Data Time-Out

Figure 24-27 shows the DCRC event condition asserted when there is read data time-out.

Figure 24-27. Read Data Time-Out

$t_1$  – Data time-out counter is loaded and starts after command transmission.

$t_2$  – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

$t_3$  – Data time-out counter is loaded and starts after data block + CRC transmission.

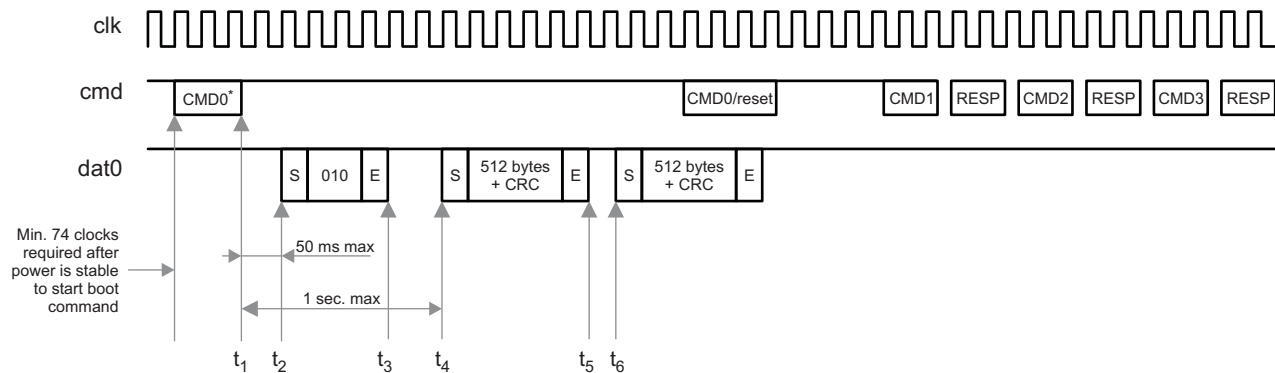

$t_4$  – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

### 24.4.9.5 Boot Acknowledge Time-Out

Figure 24-28 shows the DCRC event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

**Figure 24-28. Boot Acknowledge Time-Out When Using CMD0**

\* Refer to MMC specification for correct Argument

mmchs-095

- $t_1$  – Data time-out counter is loaded and starts after CMD0.
- $t_2$  – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- $t_3$  – Data time-out counter is loaded and starts.
- $t_4$  – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- $t_5$  – Data time-out counter is loaded and starts after data + CRC transmission.
- $t_6$  – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

Figure 24-29 shows the DCRC event condition asserted when there is boot acknowledge time-out when the CMD line is tied to 0.

**Figure 24-29. Boot Acknowledge Time-Out When CMD Line Tied to 0**

mmchs-096

- $t_1$  – Data time-out counter is loaded and starts after the CMD line is tied to 0.
- $t_2$  – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- $t_3$  – Data time-out counter is loaded and starts.
- $t_4$  – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.
- $t_5$  – Data time-out counter is loaded and starts after data + CRC transmission.
- $t_6$  – Data time-out counter stops and if it is 0, the [MMCHS\\_STAT\[21\]](#) DCRC bit is generated.

### 24.4.10 Auto Command 12 Timings

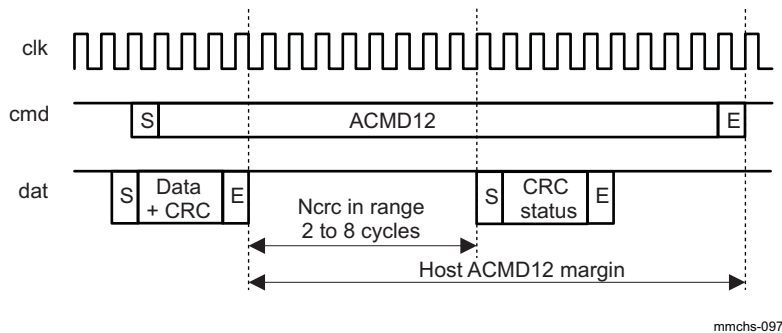

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (ACMD12) end bit.

#### 24.4.10.1 ACMD12 Timings During Write Transfer

A margin named *Ncrc* in the range of two to eight cycles has been defined for SDR50 card components for write data transfers, because the ACMD12 end bit must arrive after the CRC status end bit.

Figure 24-30 shows the ACMD12 timings during write transfer.

Figure 24-30. ACMD12 Timings During Write Transfer

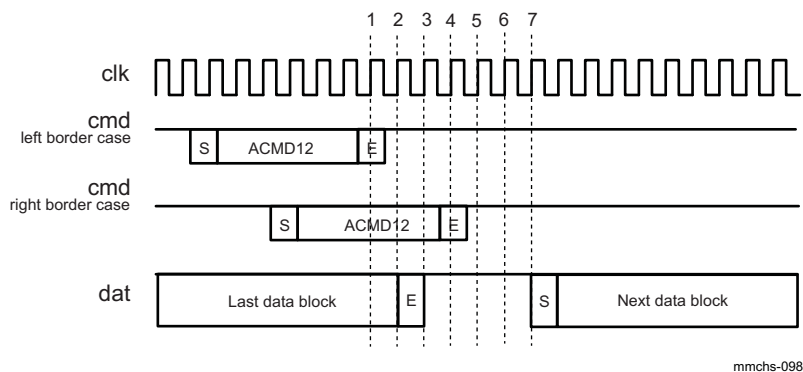

The host controller has a margin of 18 clock cycles to ensure that the ACMD12 end bit arrives after the CRC status. This margin does not depend on the MMC bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

#### 24.4.10.2 ACMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards has been extended from two cycles to four cycles. It provides more flexibility for the host ACMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the left border case defined by the SD UHS specification.

Figure 24-31 shows ACMD12 timings during read transfer.

Figure 24-31. ACMD12 Timings During Read Transfer

The ACMD12 arrival sent by the host controller is not sensitive to the MMC bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

### 24.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop while it is still not finished. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)
- Continuous stream transfers (transfer has an infinite length)

---

**NOTE:** Because the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

---

The MMC/SD/SDIOi controller includes two features that make a transfer stop more convenient and easier to manage:

- ACMD12 (for MMC and SD only):

This feature is enabled by setting the MMCI.MMCHS\_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the ACMD12 feature is enabled, the MMC/SD/SDIOi controller automatically issues a CMD12 command when the expected number of blocks is exchanged.

- Stop at block gap:

This feature is enabled by setting the MMCI.MMCHS\_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

- ADMA mode:

For ADMA-capable modules (MMC1 and MMC2) (for more information, see [Section 24.4.5, DMA Modes](#)), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

---

**NOTE:** For MMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has a read-wait capability.

---

[Table 24-20](#) shows the common way to stop a transfer, indicating the command to send and the features to enable.

**Table 24-20. MMC/SD/SDIOi Controller Transfer Stop Command Summary**

		Write Transfer		Read Transfer	
		SD/MMC	SDIO	SD/MMC	SDIO
Single block		Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.	Transfer ends automatically. Wait TC.
Multiblocks (finite or infinite)	Before the programmed block boundary	Send CMD12. Wait TC.	Send CMD52. Wait TC.	Send CMD12. Wait TC.	Send CMD52. Wait TC.
	Stop at the end of the transfer (finite transfer only)	ACMD12 active Transfer ends automatically. Wait TC.	Set MMCI.MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52. Wait TC.	ACMD12 active Transfer ends automatically. Wait TC.	<b>If READ_WAIT supported</b> Stop at block gap. Wait TC. <hr/> <b>If READ_WAIT not supported</b> Send CMD52. Wait TC.

**NOTE:** The MMC/SD/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

### 24.4.12 Retention Mode

This mode is enabled if the generic parameter bit `MMCHS_HL_HWINFO[6] RETMODE` is set to 1 during module integration. The controller can enter into retention mode when the module was previously set in idle mode. When the module goes into retention mode all clocks are left inactive at low level except for registers that are driven by a falling-edge clock, which are kept as free during retention mode. This also means that all divided functional clock subdomains are forced low when the module enters smart-idle mode. In force-idle mode, the system must ensure that all divided functional clocks are set inactive or are in bypass mode by configuring the `MMCHS_SYSCTL` register correctly before entering idle mode (under software responsibility).

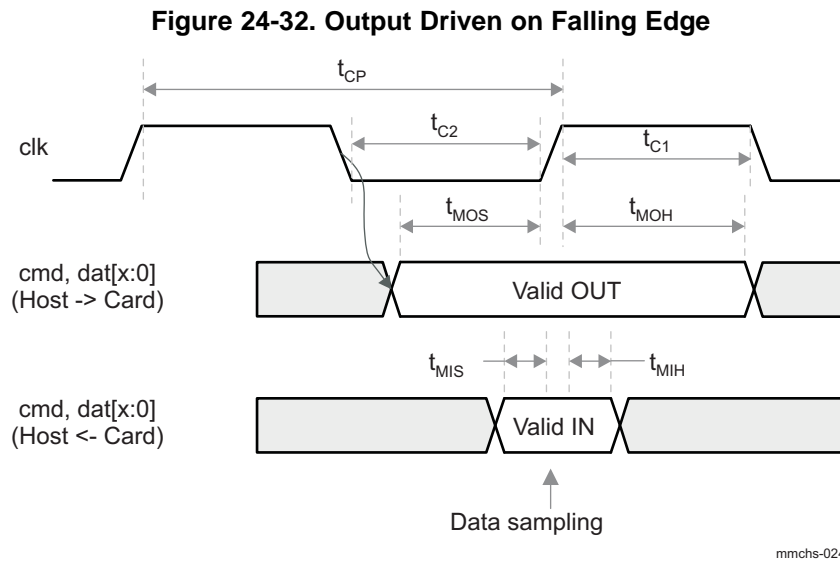

### 24.4.13 Output Signals Generation

The MMC/SD/SDIO output signals can be driven on the falling edge or rising edge, depending on the `MMCHS_HCTL[2] HSPE` bit. This feature allows reaching better timing performance, and thus increasing data transfer frequency.

#### 24.4.13.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, the `MMCHS_HCTL[2] HSPE` bit is set to 0.

Figure 24-32 shows the output signals of the module when generating from the falling edge of the MMC clock.

#### 24.4.13.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting the `MMCHS_HCTL[2] HSPE` bit to 1. The controller must be set in this mode to support SDR transfers.

**NOTE:** Do not use this feature in DDR mode (when the `MMCHS_CON[19] DDR` bit is set to 1).

Figure 24-33 shows the output signals of the module when generating from the rising edge of the MMC clock.

**Figure 24-33. Output Driven on Rising Edge**

mmchs-025

### 24.4.14 Card Boot Mode Management

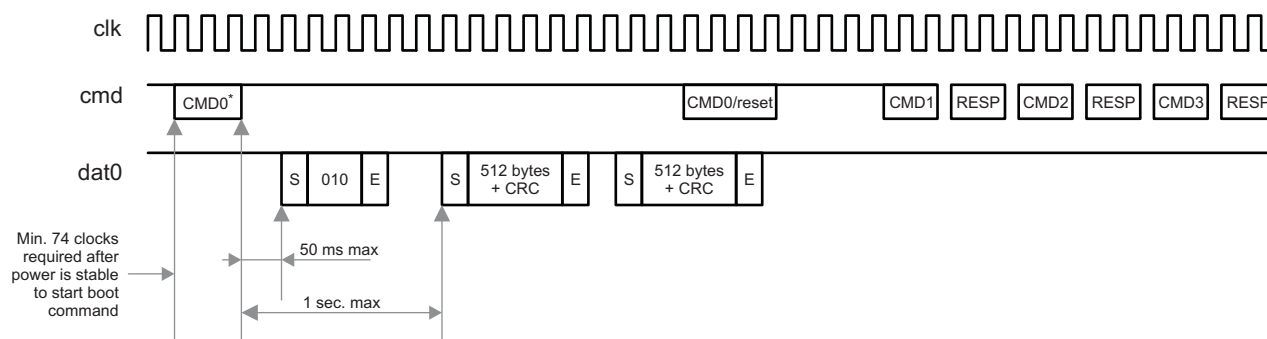

Boot operation mode allows the MMC/SD/SDIOi host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

Power-on boot defines a way for the boot code to be accessed by the MMC/SD/SDIOi host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

#### 24.4.14.1 Boot Mode Using CMD0

Figure 24-34 shows the timing diagram of a boot sequence using CMD0.

**Figure 24-34. Boot Mode Using the CMD0 Timing Diagram**

\* Refer to MMC specification for correct Argument

mmchs-026

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 24.5.1.2.3.1, Boot Using the CMD0](#).

#### 24.4.14.2 Boot Mode With CMD Line Tied to 0

Figure 24-35 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 24-35. Boot Mode With CMD Line Tied to 0 Timing Diagram

mmchs-027

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 24.5.1.2.3.2, Boot With CMD Line Tied to 0](#).

#### 24.4.15 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (the [MMCHS\\_CON\[12\]](#) CEATA and [MMCHS\\_CMD\[2\]](#) ACEN bits set to 1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- The [MMCHS\\_CON\[12\]](#) CEATA bit is set to 1.
- The [MMCHS\\_CON\[2\]](#) bit HR set to 1.
- Clear the [MMCHS\\_ARG](#) register.
- Write into the [MMCHS\\_CMD](#) register with the value 0x00000000.

When a command completion disable token was emitted (that is, the [MMCHS\\_STAT\[0\]](#) CC bit received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when command completion signal disable (CCSD) is emitted during the last data block transfer, and the sequence on the command line is sent close to the command completion signal (CCS) token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:  
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:  
The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:  
Only the interrupt CIRQ is generated when CCS is detected.

#### 24.4.16 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register ([MMCHS\\_FE](#)) is used to control the error interrupt status and ACMD12 error status.

The system test register ([MMCHS\\_SYSTEST](#)) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the [MMCHS\\_CON\[4\]](#) MODE bit = 1) for boundary connectivity verification.

#### 24.4.17 MMC/SD/SDIO Hardware Status Features

[Table 24-21](#) describes the MMC/SD/SDIO hardware status features.

**Table 24-21. MMC/SD/SDIO Hardware Status Features**

Feature	Type	Register/Bit Field/Observability Control	Description
Interrupt flags		See <a href="#">Section 24.4.4</a> , <i>Interrupt Requests</i> .	
CMD line signal level	Status	<a href="#">MMCHS_PSTATE[24]</a> CLEV	Indicates the level of the command line
DAT lines signal level	Status	<a href="#">MMCHS_PSTATE[23:20]</a> DLEV	Indicates the level of the data lines
Buffer read enable	Status	<a href="#">MMCHS_PSTATE[11]</a> BRE	Readable data exists in the buffer.
Buffer write enable	Status	<a href="#">MMCHS_PSTATE[10]</a> BWE	Indicates whether there is enough space in the buffer to write BLEN bytes of data
Read transfer active	Status	<a href="#">MMCHS_PSTATE[9]</a> RTA	Used to detect completion of a read transfer.
Write transfer active	Status	<a href="#">MMCHS_PSTATE[8]</a> WTA	Indicates a write transfer active
Data line active	Status	<a href="#">MMCHS_PSTATE[2]</a> DLA	Indicates whether the data lines are active
Command Inhibit (DAT lines)	Status	<a href="#">MMCHS_PSTATE[1]</a> DATI	Indicates whether issuing of command using data lines is allowed
Command inhibit (CMD line)	Status	<a href="#">MMCHS_PSTATE[0]</a> CMDI	Indicates whether issuing of command using command line is allowed

## 24.5 MMC/SD/SDIO Programming Guide

### 24.5.1 Low-Level Programming Models

#### 24.5.1.1 Global Initialization

##### 24.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules. For more information, see [Section 24.3, MMC/SD/SDIO Integration](#), and [Section 24.2, MMC/SD/SDIO Environment](#).

**Table 24-22. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. See <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing and configuration must be set in the control module. See <a href="#">Chapter 18, Control Module</a> .
(optional) MPU INTC (or DSP INTC)	MPU INTC configuration must be done to enable the interrupts from the MMCHS module. See <a href="#">Chapter 17, Interrupt Controllers</a> .
(optional) sDMA (or dDMA)	DMA configuration must be done to enable the module DMA channel requests. See <a href="#">Chapter 16, sDMA</a> .
(optional) Interconnect	For more information about the interconnect configuration, see <a href="#">Chapter 13, Interconnect</a> .

**NOTE:** The MPU/DSP INTC and the sDMA/dDMA configurations are necessary if the interrupt and DMA-based communication modes are used.

##### 24.5.1.1.2 MMC/SD/SDIO Host Controller Initialization Flow

[Table 24-23](#) shows the general boot process.

**Table 24-23. MMC/SD/SDIO Controller Meta Initialization Steps**

Step	Access Type	Register/Bit Field/Programming Model	Value
Initialize clocks.		See <a href="#">Section 24.5.1.1.2.1</a> .	
Software reset of the controller.		See <a href="#">Section 24.5.1.1.2.2</a> .	
Set module hardware capabilities.		See <a href="#">Section 24.5.1.1.2.3</a> .	
Set module idle and wake-up modes.		See <a href="#">Section 24.5.1.1.2.4</a> .	

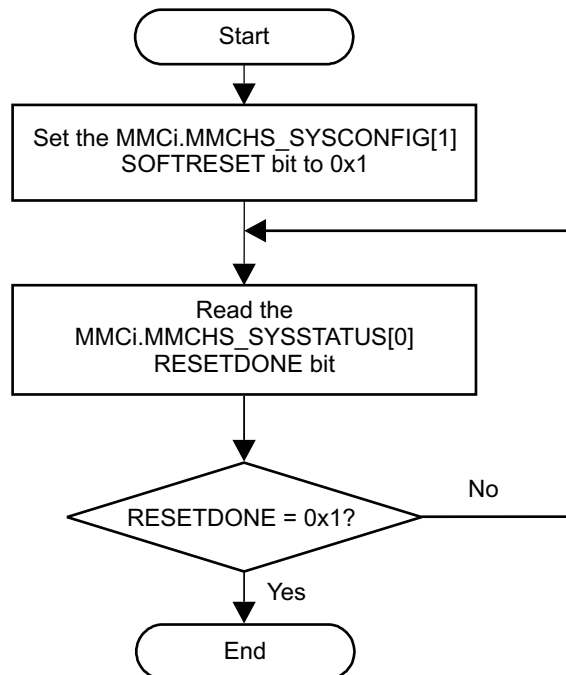

##### 24.5.1.1.2.1 Enable Interface and Functional clock for MMC Controller

Before any MMCHS register access, the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See [Section 3.6.10.4, Clock Domain Module Attributes](#), in [Chapter 3, Power, Reset, and Clock Management](#).

##### 24.5.1.1.2.2 MMCHS Soft Reset Flow

[Figure 24-36](#) shows the soft reset process of the MMCHS controller.

**Figure 24-36. MMC/SD/SDIO Controller Software Reset Flow**

mmchs-028

**Table 24-24. Register Call Summary for Main Sequence – Software Reset Flow**

Register Name	Register Name
MMCHS_SYSCONFIG	MMCHS_SYSSTATUS

#### 24.5.1.1.2.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.MMCHS\_CAPA[26:24] and MMCi.MMCHS\_CUR\_CAPA[23:0] bit fields before the MMC/SD/SDIO host driver is started.

#### 24.5.1.1.2.4 Wake-Up Configuration

Table 24-25 describes the MMCHS controller wake-up configuration.

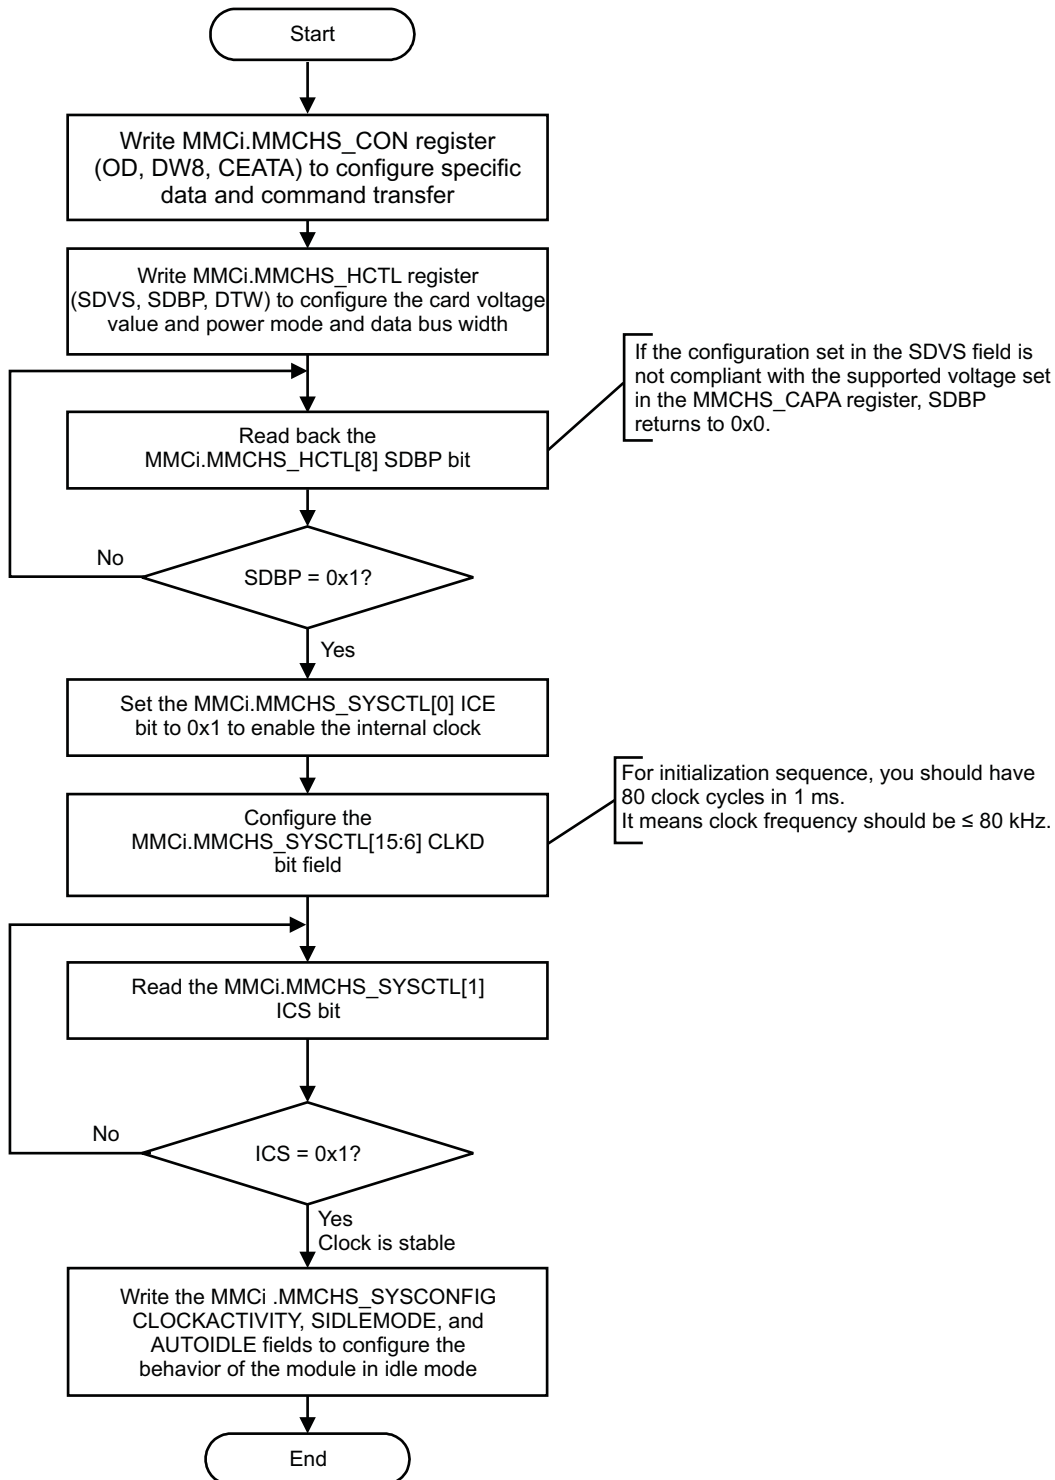

**Table 24-25. MMC/SD/SDIO Controller Wake-Up Configuration**

Step	Access Type	Register/Bit Field/Programming Model	Value
Configure wake-up bit (if necessary).	W	MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP	0x1
Enable wake-up events on SD card interrupt (if necessary).	W	MMCi.MMCHS_HCTL[24] IWE	0x1
<b>SDIO card only:</b> Enable card interrupt (if necessary).	W	MMCi.MMCHS_IE[8] CIRQ_ENABLE	0x1

24.5.1.1.2.5 MMC Host and Bus Configuration

Figure 24-37 shows the MMC bus configuration process.

Figure 24-37. MMC/SD/SDIO Controller Bus Configuration

mmchs-029

**Table 24-26. Register Call Summary for Main Sequence – Bus Configuration**

Register Name	Register Name
<a href="#">MMCHS_CON</a>	<a href="#">MMCHS_HCTL</a>
<a href="#">MMCHS_SYSCONFIG</a>	<a href="#">MMCHS_SYCTL</a>

## 24.5.1.2 Operational Modes Configuration

### 24.5.1.2.1 Basic Operations for MMC/SD/SDIO Host Controller

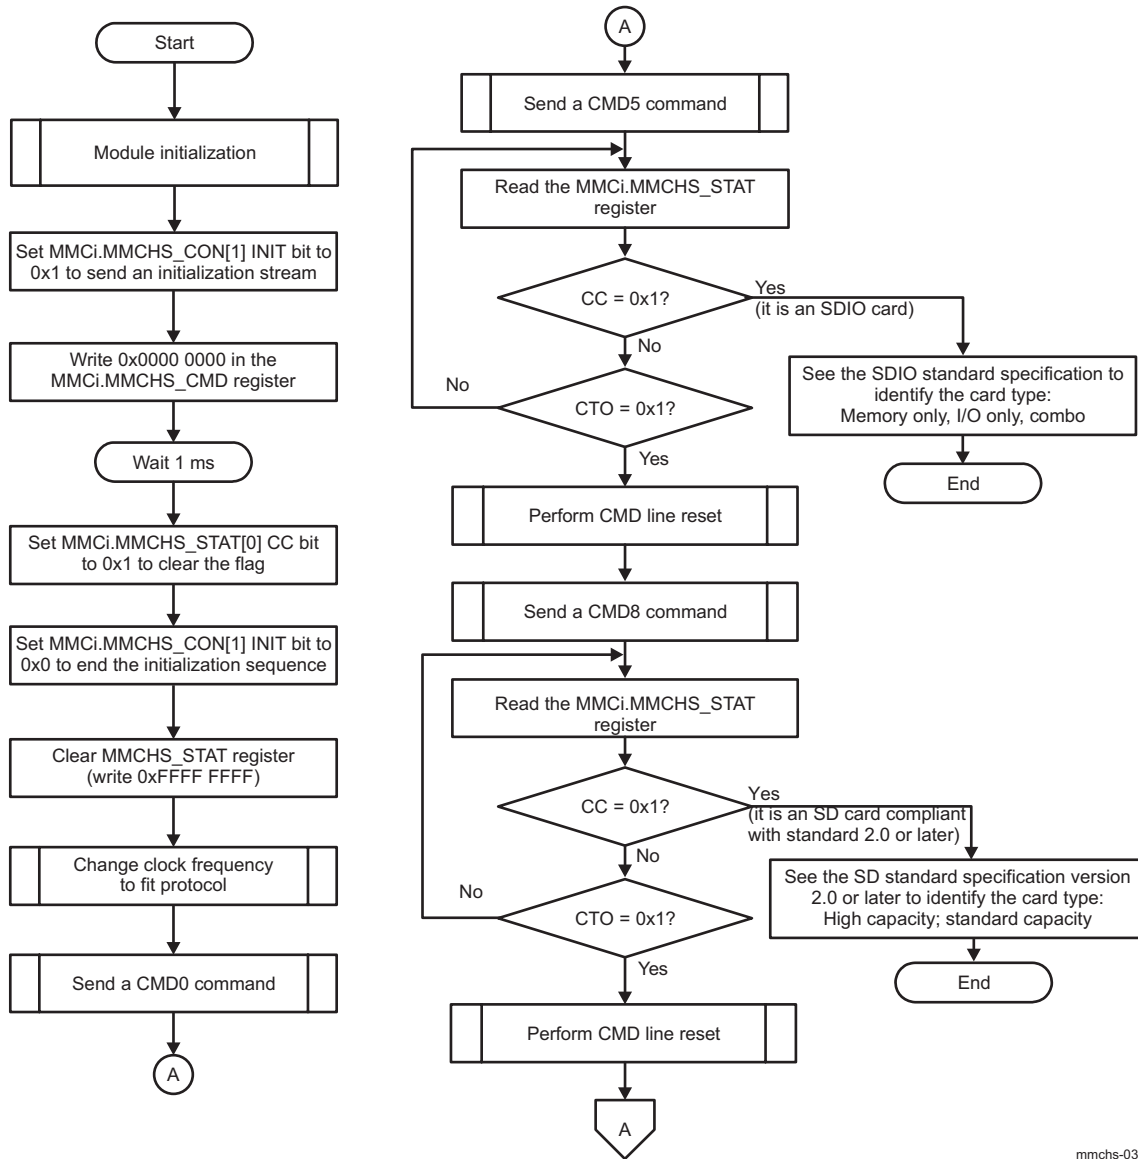

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

#### 24.5.1.2.1.1 Card Detection, Identification, and Selection

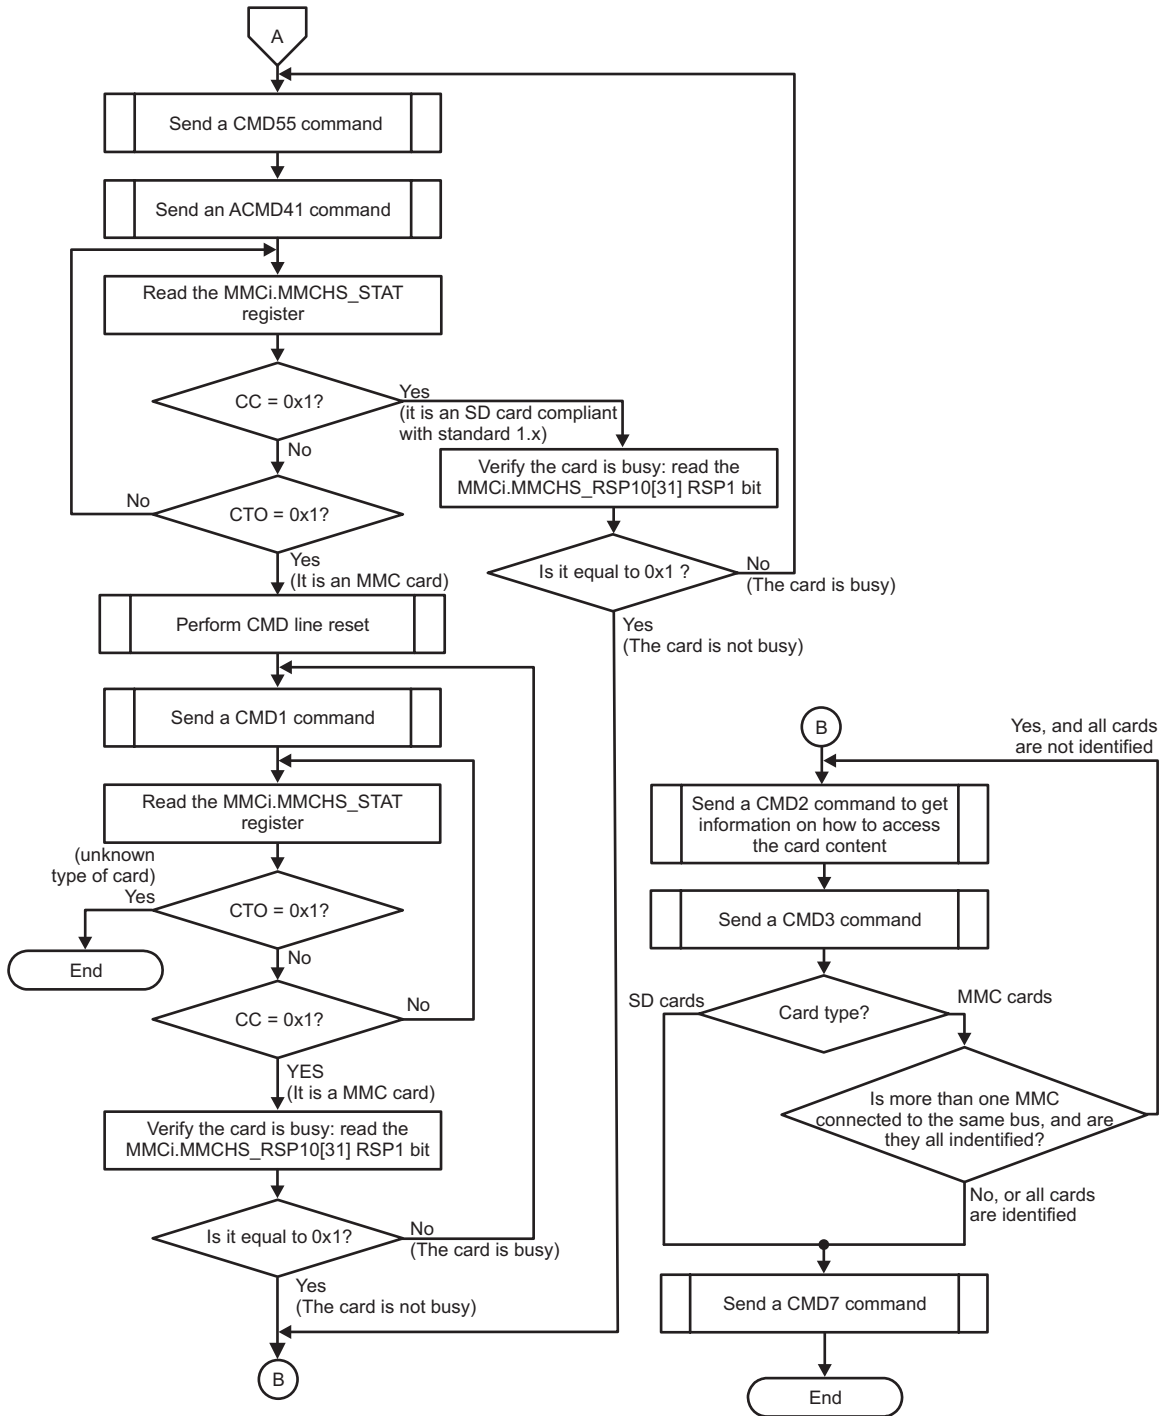

[Figure 24-38](#) and [Figure 24-39](#) show the card identification and selection process.

Figure 24-38. MMC/SD/SDIO Controller Card Identification and Selection – Part 1

mmchs-030

Initialize module and card.	<a href="#">Section 24.5.1.1.2</a> <a href="#">Section 24.5.1.2.1.1</a>
Send a SEND_CSD command (CMD9).	<a href="#">Section 24.5.1.2.1.7.1</a>
Send SWITCH command (CMD6).	<a href="#">Section 24.5.1.2.1.7.1</a>

### 24.5.1.2.2 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the settings of the CONTROL.CONTROL\_PBIASLITE register.

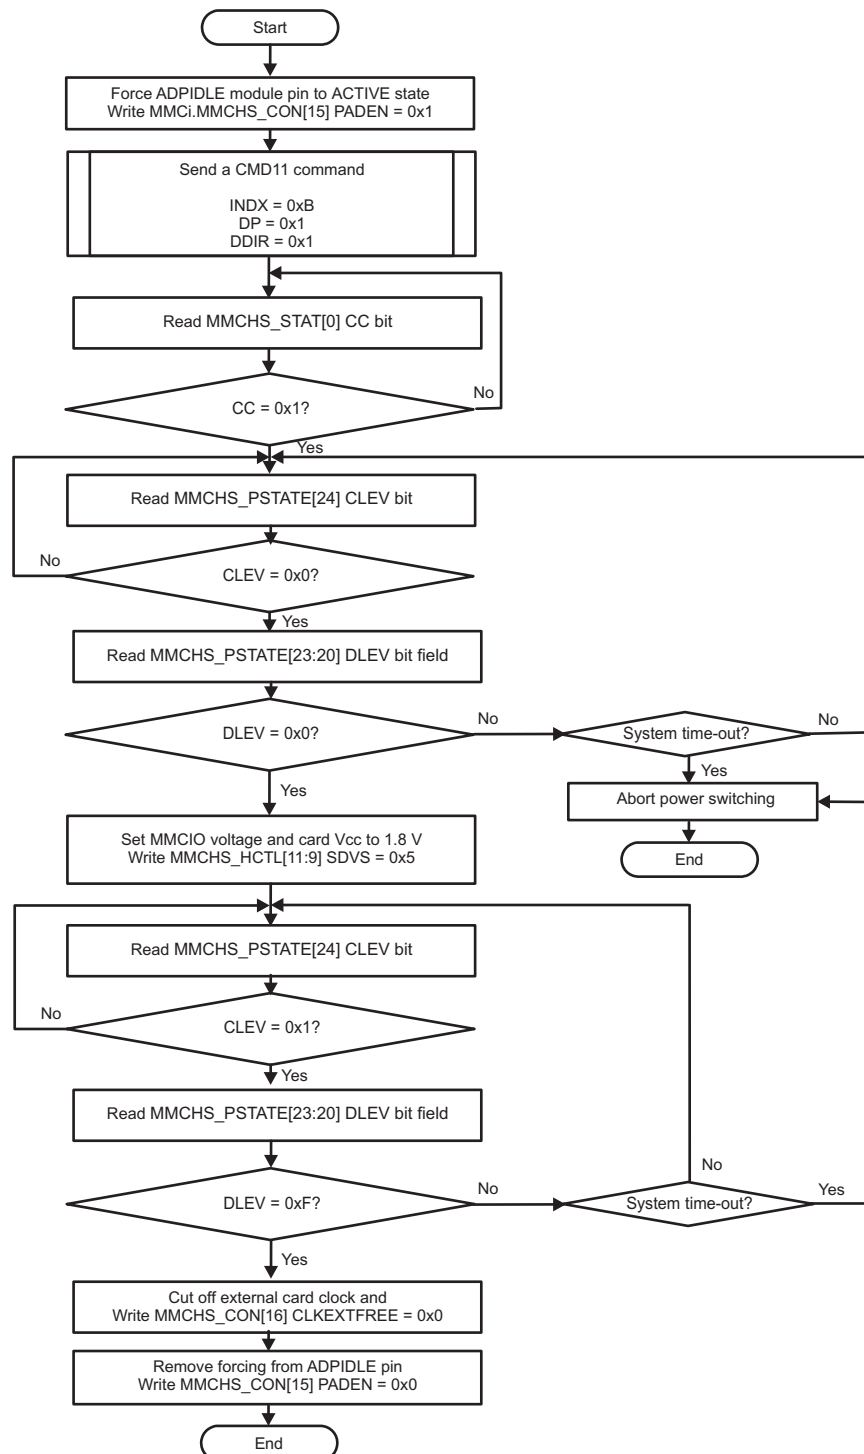

For more information about the MMC1\_PBIAS cell, see [Section 18.4.9](#), *Extended-Drain I/O and PBIAS Cell*, in [Chapter 18](#), *Control Module*.

For the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller, see [Section 18.5.1.2.2](#), *Extended-Drain I/Os and PBIAS Cell Programming Guide*, in [Chapter 18](#), *Control Module*.

#### **CAUTION**

The BIAS voltage must be set using the procedure described in [Section 18.5.1.2.2](#), *Extended-Drain I/Os and PBIAS Cell Programming Guide*, in [Chapter 18](#), *Control Module*. Failure to follow this procedure can damage the MMCHS interface.

[Figure 24-50](#) shows how to configure the MMCHS controller to fit with power switching sequence.

**Figure 24-50. MMC/SD/SDIO Power Switching Procedure**

mmchs-042

**Table 24-50. Register Call Summary for Main Sequence – Power Switching Procedure**

Register Name	Register Name
MMCHS_STAT	MMCHS_PSTATE
MMCHS_CMD	MMCHS_CON

Subprocess Name	Cross-Reference
Send a READ_DAT_UNTIL_STOP command (CMD11).	<a href="#">Section 24.5.1.2.1.7.1</a>

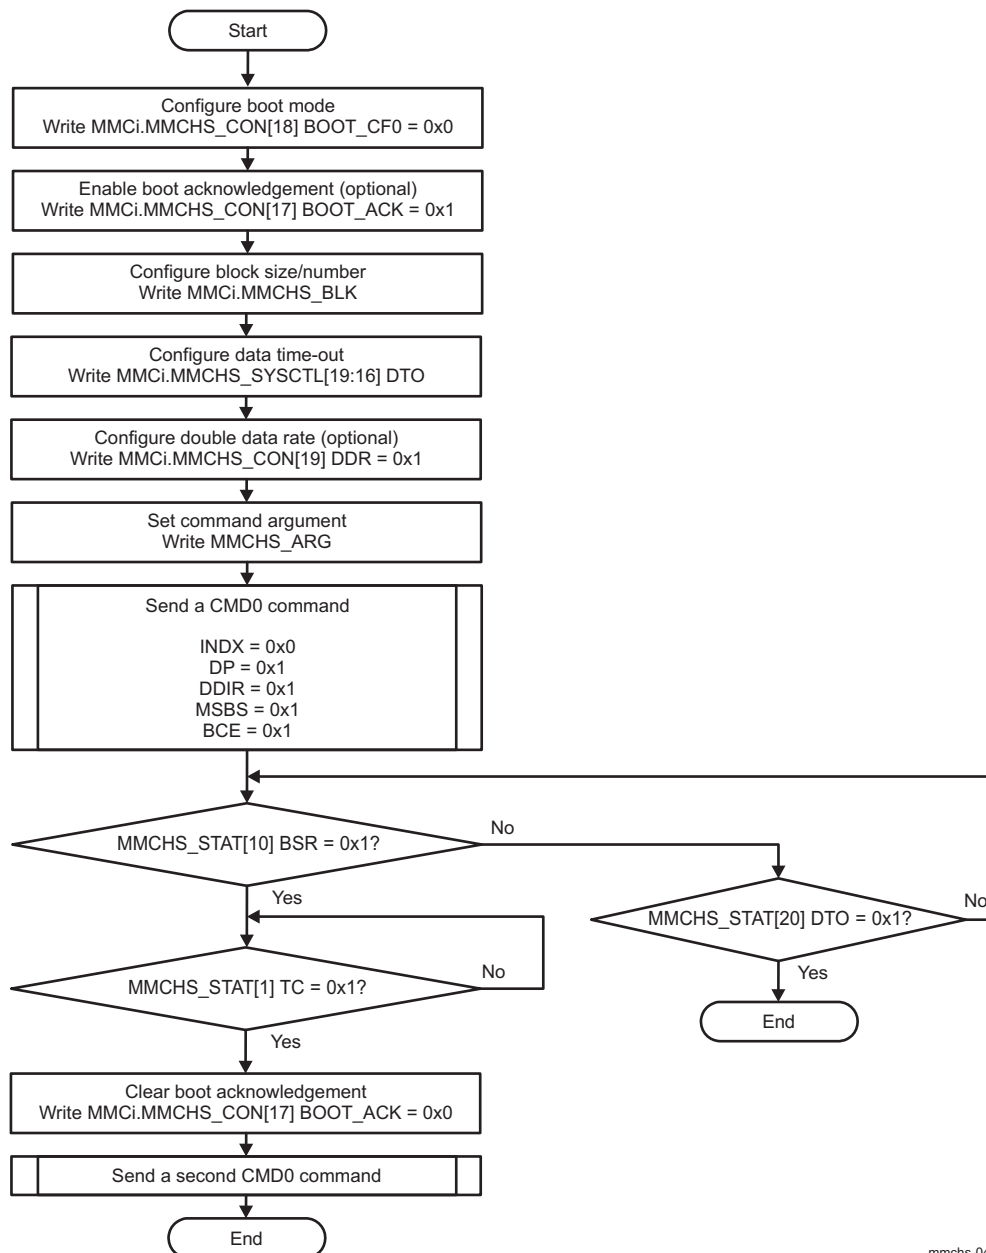

**24.5.1.2.3 Boot Mode Configuration**

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

**24.5.1.2.3.1 Boot Using CMD0**

Figure 24-51 shows the necessary steps to configure the controller boot mode using CMD0.

**Figure 24-51. MMC/SD/SDIO Controller Boot Using CMD0**

mmchs-043

To abort a boot sequence, the system must issue a CMD0 with the [MMCHS\\_CMD](#)[23:22] CMD\_TYPE bit field set to 0x3 (the [MMCHS\\_CON](#)[17] BOOT\_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

**Table 24-52. Register Call Summary for Main Sequence – Boot Using CMD0**

Register Name	Register Name	Register Name
<a href="#">MMCHS_CON</a>	<a href="#">MMCHS_BLK</a>	<a href="#">MMCHS_SYSCTL</a>

**Table 24-53. Subprocess Call Summary for Main Sequence – Boot Using CMD0**

Subprocess Name	Cross-Reference
Send a CMD0 command.	<a href="#">Section 24.5.1.2.1.7.1</a>

24.5.1.2.3.2 Boot With CMD Line Tied to 0

Figure 24-52 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

Figure 24-52. MMC/SD/SDIO Controller Boot With CMD Line Tied to 0

mmchs-044

To abort the boot sequence, the system must clear the **MMCHS\_CON[18] BOOT\_CF0** bit to 0x0 during the transfer to abort the transfer and enable the card to exit from boot state.

<b>Physical Address</b>	0x4809 C124 0x480B 4124 0x480A D124 0x480D 1124 0x480D 5124	<b>Instance</b>  MMCHS1 MMCHS2 MMCHS3 MMCHS4 MMCHS5																																																																
<b>Description</b>	Card status response error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit <a href="#">MMCHS_CSRE[i]</a> is set to 1, if the corresponding bit at the same position in the response <a href="#">MMCHS_RSP10[i]</a> is set to 1, the host controller indicates a card error ( <a href="#">MMCHS_STAT[CERR]</a> ) interrupt status to avoid the host driver reading the response register ( <a href="#">MMCHS_RSP10</a> ). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register ( <a href="#">MMCHS_RSP76</a> ) for possible card errors.

<b>Address Offset</b>	0x0000 0128		
<b>Physical Address</b>	0x4809 C128 0x480B 4128 0x480A D128 0x480D 1128 0x480D 5128	<b>Instance</b>	MMCHS1 MMCHS2 MMCHS3 MMCHS4 MMCHS5
<b>Description</b>	<p>System Test register</p> <p>This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.</p> <p>Note: In SYSTEST mode, a write into <b>MMCHS_CMD</b> register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (<b>MMCHS_BLK</b>[11:0] BLEN) and the Blocks count for current transfer (<b>MMCHS_BLK</b>[31:16] NBLK) are needed to generate a Buffer write ready interrupt (<b>MMCHS_STAT</b>[4] BWR) or a Buffer read ready interrupt (<b>MMCHS_STAT</b>[5] BRR) and DMA requests if enabled.</p>

Bits	Field Name	Description	Type	Reset
31:22	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored. Reads return 0.	R	0x000

Bits	Field Name	Description	Type	Reset
21	SDMA_LNE	<p>Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to <a href="#">MMCHS_DATA</a> register or late de-assertion, request remains active until last allowed data written into <a href="#">MMCHS_DATA</a>.</p> <p>0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion</p>	RW	0
20	DMA_MNS	<p>DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter <a href="#">MMCHS_HL_HWINFO[0]</a> MADMA_EN is asserted to 1.</p> <p>0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.</p>	RW	0
19	DDR	<p>Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of <a href="#">MMCHS_SYSCTL[15:6]</a> CLKD, it is insensitive to <a href="#">MMCHS_HCTL[2]</a> HSPE setting.</p> <p>0x0: Standard mode : data are transmitted on a single edge depending on <a href="#">MMCHS_HCTL[2]</a> HSPE. 0x1: Data Bytes and CRC are transmitted on both edge.</p>	RW	0
18	BOOT_CFO	<p>Boot status supported: This register is set when the CMD line need to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in <a href="#">MMCHS_CMD</a>. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction.</p> <p>Write 0x0: CMD line is released when it was previously forced to 0 by a boot sequence. Read 0x0: CMD line not forced Read 0x1: CMD line forced to 0 is enabled Write 0x1: CMD line forced to 0 is enabled and will be active after writing into <a href="#">MMCHS_CMD</a></p>	RW	0
17	BOOT_ACK	<p>Book acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated.</p> <p>0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.</p>	RW	0
16	CLKEXTFREE	<p>External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if <a href="#">MMCHS_SYSCTL[2]</a> CEN is set.</p> <p>0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if <a href="#">MMCHS_SYSCTL[2]</a> CEN is set.</p>	RW	0

Bits	Field Name	Description	Type	Reset
15	PADEN	<p>Control Power for MMC Lines: This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control <a href="#">MMCHS_CON[11]</a> CTPL bit.</p> <p>0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms. 0x1: ADPIDLE module pin is forced to active state.</p>	RW	0
14	OBIE	<p>Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: Out-of-Band interrupt detection disabled 0x1: Out-of-Band interrupt detection enabled</p>	RW	0
13	OBIP	<p>Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration. 0x0: active high level 0x1: active low level</p>	RW	0
12	CEATA	<p>CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features. 0x0: Standard MMC/SD/SDIO mode. 0x1: CE-ATA mode next commands are considered as CE-ATA commands.</p>	RW	0
11	CTPL	<p>Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current. SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers. 0x0: Disable all the input buffers outside of a transaction. 0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.</p>	RW	0
10:9	DVAL	<p>Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: 33 us debounce period 0x1: 231 us debounce period 0x2: 1 ms debounce period 0x3: 8,4 ms debounce period</p>	RW	0x3

Bits	Field Name	Description	Type	Reset
8	WPP	<p>Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p>	RW	0
7	CDP	<p>Card detect polarity All cards This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p>	RW	0
6	MIT	<p>MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (<a href="#">MMCHS_CMD</a>) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response.</p> <p>0x0: Command timeout enabled 0x1: Command timeout disabled</p>	RW	0
5	DW8	<p>8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6).</p> <p>0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)</p>	RW	0
4	MODE	<p>Mode select All cards These bits select between Functional mode and SYSTEST mode.</p> <p>0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register.</p> <p>0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.</p>	RW	0

Bits	Field Name	Description	Type	Reset
3	STR	<p>Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer 0x1: Stream oriented data transfer</p>	RW	0
2	HR	<p>Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC [1] specification). In order to have the host response to be generated in open drain mode, the register <a href="#">MMCHS_CON[0]</a> OD must be set to 1. When <a href="#">MMCHS_CON[12]</a> CEATA is set to 1 and <a href="#">MMCHS_ARG</a> set to 0x00000000 when writing 0x00000000 into <a href="#">MMCHS_CMD</a> register, the host controller performs a 'command completion signal disable' token that is, CMD line held to 0 during 47 cycles followed by a 1. 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p>	RW	0
1	INIT	<p>Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (<a href="#">MMCHS_SYSCTL[15:6]</a> CLKD) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification [1], or section 6.4 in the SD card specification [2]). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.</p>	RW	0
0	OD	<p>Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register <a href="#">MMCHS_CON[2]</a> HR) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response</p>	RW	0

		0x2C: CMD44 or ACMD44 0x2D: CMD45 or ACMD45 0x2E: CMD46 or ACMD46 0x2F: CMD47 or ACMD47 0x30: CMD48 or ACMD48 0x31: CMD49 or ACMD49 0x32: CMD50 or ACMD50 0x33: CMD51 or ACMD51 0x34: CMD52 or ACMD52 0x35: CMD53 or ACMD53 0x36: CMD54 or ACMD54 0x37: CMD55 or ACMD55 0x38: CMD56 or ACMD56 0x39: CMD57 or ACMD57 0x3A: CMD58 or ACMD58 0x3B: CMD59 or ACMD59 0x3C: CMD60 or ACMD60 0x3D: CMD61 or ACMD61 0x3E: CMD62 or ACMD62 0x3F: CMD63 or ACMD63		
23:22	CMD_TYPE	Command type This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. 0x0: Others Commands 0x1: CMD52 for writing "Bus Suspend" in CCCR 0x2: CMD52 for writing "Function Select" in CCCR 0x3: Abort command CMD12, CMD52 for writing " I/O Abort" in CCCR	RW	0x0
21	DP	Data present select This register indicates that data is present and DAT line shall be used. It must be set to 0 in the following conditions: - command using only CMD line - command with no data transfer but using busy signal on DAT[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error ( <a href="#">MMCHS_STAT[19]</a> CIE set to 1) Note: The register CICE cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0

Bits	Field Name	Description	Type	Reset
19	CCCE	<p>Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (<a href="#">MMCHS_STAT[17]</a> CCRC set to 1). Note: The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued.</p> <p>0x0: CRC7 check disable 0x1: CRC7 check enable</p>	RW	0
18	RESERVED	<p>Reserved. This bit is initialized to zero, and writes to it are ignored.</p>	R	0
17:16	RSP_TYPE	<p>Response type This bits defines the response type of the command</p> <p>0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response</p>	RW	0x0
15:6	RESERVED	<p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p>	R	0x000
5	MSBS	<p>Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0.</p> <p>0x0: Single block. If this bit is 0, it is not necessary to set the register <a href="#">MMCHS_BLK[31:16]</a> NBLK. 0x1: Multi block. When Block Count is disabled (<a href="#">MMCHS_CMD[1]</a> BCE is set to 0) in Multiple block transfers (<a href="#">MMCHS_CMD[5]</a> MSBS is set to 1), the module can perform infinite transfer.</p>	RW	0
4	DDIR	<p>Data transfer Direction Select This bit defines either data transfer will be a read or a write.</p> <p>0x0: Data Write (host to card) 0x1: Data Read (card to host)</p>	RW	0
3	RESERVED	<p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p>	R	0
2	ACEN	<p>Auto CMD12 Enable SDIO does not support this feature. When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, safe commands do not require CMD12.</p> <p>0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.</p>	RW	0

Bits	Field Name	Description	Type	Reset
1	BCE	Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK). When Block Count is disabled (MMCHS_CMD[1] BCE is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS is set to 1), the module can perform infinite transfer.  0x0: Block count disabled for infinite transfer.  0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable This bit is used to enable DMA mode for host data access.  0x0: DMA mode disable 0x1: DMA mode enable	RW	0

<b>Address Offset</b>	0x0000 0220		
<b>Physical Address</b>	<a href="#">0x4809 C220</a> <a href="#">0x480B 4220</a> <a href="#">0x480A D220</a> <a href="#">0x480D 1220</a> <a href="#">0x480D 5220</a>	<b>Instance</b>	MMCHS1 MMCHS2 MMCHS3 MMCHS4 MMCHS5
<b>Description</b>	Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=>0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=>0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=>0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad

RESERVED								RESERVED				RESERVED				SDVS		SDBP		CDSS	CDTL	RESERVED	DMAS		HSPE	DTW	LED				

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x0
27	OBWE	Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled ( <a href="#">MMCHS_SYSCONFIG[2]</a> ENAWAKEUP). The write to this register is ignored when <a href="#">MMCHS_CON[14]</a> OBIE is not set.  0x0: Disable wakeup on 'Out-of-Band' Interrupt 0x1: Enable wakeup on 'Out-of-Band' Interrupt	RW	0
26	REM	Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled ( <a href="#">MMCHS_SYSCONFIG[2]</a> ENAWAKEUP).  0x0: Disable wakeup on card removal 0x1: Enable wakeup on card removal	RW	0

Bits	Field Name	Description	Type	Reset
25	INS	<p>Wakeup event enable on SD card insertion This bit enables wakeup events for card insertion assertion. Wakeup is generated if the wakeup feature is enabled (<a href="#">MMCHS_SYSCONFIG[2] ENAWAKEUP</a>).</p> <p>0x0: Disable wakeup on card insertion 0x1: Enable wakeup on card insertion</p>	RW	0
24	IWE	<p>Wakeup event enable on SD card interrupt This bit enables wakeup events for card interrupt assertion. Wakeup is generated if the wakeup feature is enabled (<a href="#">MMCHS_SYSCONFIG[2] ENAWAKEUP</a>).</p> <p>0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt</p>	RW	0
23:20	RESERVED	<p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p>	R	0x0
19	IBG	<p>Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0.</p> <p>0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode</p>	RW	0
18	RWC	<p>Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (<a href="#">MMCHS_HCTL[16] SBGR</a>) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line.</p> <p>0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control</p>	RW	0
17	CR	<p>Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (<a href="#">MMCHS_HCTL[16] SBGR</a>). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (<a href="#">MMCHS_PSTATE[2] DLA</a>) or transferring data (<a href="#">MMCHS_PSTATE[8] WTA</a>). The Stop at block gap request must be disabled (<a href="#">MMCHS_HCTL[16] SBGR = 0</a>) before setting this bit.</p> <p>0x0: No affect 0x1: transfer restart</p>	RW	0
16	SBGR	<p>Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (<a href="#">MMCHS_HCTL[17] CR</a>) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (<a href="#">MMCHS_STAT[1] TC</a> set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (<a href="#">MMCHS_DATA</a>).</p> <p>0x0: Transfer mode 0x1: Stop at block gap</p>	RW	0
15:12	RESERVED	<p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p>	R	0x0

Bits	Field Name	Description	Type	Reset
11:9	SDVS	SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system ( <a href="#">MMCHS_CAPA[26:24]</a> ) before starting a transfer.  0x5: 1.8V (Typical) 0x6: 3.0V (Typical) 0x7: 3.3V (Typical)	RW	0x0
8	SDBP	SD bus power Before setting this bit, the host driver shall select the SD bus voltage ( <a href="#">MMCHS_HCTL[11:9]</a> SDVS). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register ( <a href="#">MMCHS_CMD</a> ) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register ( <a href="#">MMCHS_CAPA[26:24]</a> ).  0x0: Power off 0x1: Power on	RW	0
7	CDSS	Card Detect Signal Selection This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing.  0x0: SDCD# is selected (for normal use) 0x1: The Card Detect Test Level is selected (for test purpose)	RW	0
6	CDTL	Card Detect Test Level: This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not.  0x0: No Card 0x1: Card Inserted	RW	0
5	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0
4:3	DMAS	DMA Select Mode: One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when <a href="#">MMCHS_HL_HWINFO[0]</a> MADMA_EN is set to 1. When <a href="#">MMCHS_HL_HWINFO[0]</a> MADMA_EN is set to 0 the bit field is read only and returned value is 0.  0x0: Reserved 0x1: Reserved 0x2: 32-bit Address ADMA2 is selected 0x3: Reserved	RW	0x0

Bits	Field Name	Description	Type	Reset
2	HSPE	<p>High Speed Enable: Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is set to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in <a href="#">MMCHS_CON</a>[19] DDR.</p> <p>0x0: Normal speed mode 0x1: High speed mode</p>	RW	0
1	DTW	<p>Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This register has no effect when the MMC 8-bit mode is selected (register <a href="#">MMCHS_CON</a>[5] DW8 set to 1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.</p> <p>0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)</p>	RW	0
0	LED	<p>Reserved bit. LED control feature is not supported This bit is initialized to zero, and writes to it are ignored.</p>	R	0

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x00
26	SRD	Software reset for DAT line. This bit is set to 1 for reset and released to 0 when completed. For more information about SRD bit manipulation, see <a href="#">Section 24.5.1.2.1.2.1, DATA Lines Reset Procedure</a> . DAT finite state machine in both clock domain are also reset. The following registers are cleared by MMCHS_SYSCTL[26] SRD: - MMCHS_DATA - MMCHS_PSTATE[11] BRE, MMCHS_PSTATE[10] BWE, MMCHS_PSTATE[9] RTA, MMCHS_PSTATE[8] WTA, MMCHS_PSTATE[2] DLA, MMCHS_PSTATE[1] DATI - MMCHS_HCTL: SBGR and CR - MMCHS_STAT: MMCHS_STAT[5] BRR, MMCHS_STAT[4] BWR, MMCHS_STAT[2] BGE and MMCHS_STAT[1] TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for DAT line	RW	0
25	SRC	Software reset for CMD line For more information about SRC bit manipulation, see <a href="#">Section 24.5.1.2.1.1, CMD Line Reset Procedure</a> . This bit is set to 1 for reset and released to 0 when completed. CMD finite state-machine in both clock domain are also reset. The following registers are cleared by MMCHS_SYSCTL[25] SRC: - MMCHS_PSTATE[0] CMDI - MMCHS_STAT[0] CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for CMD line	RW	0

Bits	Field Name	Description	Type	Reset
24	SRA	Software reset for all This bit is set to 1 for reset, and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers.  0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	RESERVED	Reserved. These bits are initialized to 0, and writes to them are ignored.	R	0x0
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bit field based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency ( <a href="#">MMCHS_CAPA[5:0]</a> TCF). If the card does not respond within the specified number of cycles, a data timeout error occurs ( <a href="#">MMCHS_STAT[20]</a> DTO). The <a href="#">MMCHS_SYSCTL[19:16]</a> DTO register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0x0: TCF x 2 <sup>13</sup> 0x1: TCF x 2 <sup>14</sup> 0xE: TCF x 2 <sup>27</sup> 0xF: Reserved	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between <a href="#">MMCi_FCLK</a> and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO).  0x0: <a href="#">MMCi_FCLK</a> bypass 0x1: <a href="#">MMCi_FCLK</a> bypass 0x2: <a href="#">MMCi_FCLK</a> / 2 0x3: <a href="#">MMCi_FCLK</a> / 3 0x3FF: <a href="#">MMCi_FCLK</a> / 1023	RW	0x000
5:3	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x0
2	CEN	Clock enable This bit controls if the clock is provided to the card or not.  0x0: The clock is not provided to the card . Clock frequency can be changed .  0x1: The clock is provided to the card and can be automatically gated when <a href="#">MMCHS_SYSCONFIG[0]</a> AUTOIDLE is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable ( <a href="#">MMCHS_SYSCTL[1]</a> ICS).	RW	0
1	ICS	Internal clock stable (status) This bit indicates either the internal clock is stable or not. Read 0x0: The internal clock is not stable.  Read 0x1: The internal clock is stable after enabling the clock ( <a href="#">MMCHS_SYSCTL[1]</a> ICE) or after changing the clock ratio ( <a href="#">MMCHS_SYSCTL[15:6]</a> CLKD).	R	0

Bits	Field Name	Description	Type	Reset
0	ICE	Internal clock enable This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.  0x0: The internal clock is stopped (very low power state).  0x1: The internal clock oscillates and can be automatically gated when <a href="#">MMCHS_SYSCONFIG[0]</a> AUTOIDLE is set to 1 (default value) .	RW	0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x0
29	BADA	Bad access to data space This bit is set automatically to indicate a bad access to buffer when not allowed: -This bit is set during a read access to the data register ( <a href="#">MMCHS_DATA</a> ) while buffer reads are not allowed ( <a href="#">MMCHS_PSTATE</a> [11] BRE = 0) -This bit is set during a write access to the data register ( <a href="#">MMCHS_DATA</a> ) while buffer writes are not allowed ( <a href="#">MMCHS_PSTATE</a> [10] BWE = 0)  Write 0x0: Status bit unchanged Read 0x0: No Interrupt. Read 0x1: Bad Access Write 0x1: Status is cleared	RW	0
28	CERR	Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error <a href="#">MMCHS_CSRE</a> is set. There is no card error detection for autoCMD12 command. The host driver shall read <a href="#">MMCHS_RSP76</a> register to detect error bits in the command response.  Write 0x0: Status bit unchanged Read 0x0: No Error Write 0x1: Status is cleared Read 0x1: Card error	RW	0
27:26	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x0
25	ADMAE	ADMA Error: This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor.  Write 0x0: Status bit unchanged Read 0x0: No Interrupt. Write 0x1: Status is cleared Read 0x1: ADMA error	RW	0
24	ACE	Auto CMD12 error This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1.  Write 0x0: Status bit unchanged Read 0x0: No Error. Read 0x1: AutoCMD12 error Write 0x1: Status is cleared	RW	0
23	CLE	Reserved. Current limit error is not supported. These bits are initialized to zero, and writes to them are ignored.	R	0

Bits	Field Name	Description	Type	Reset
22	DEB	<p>Data End Bit error</p> <p>This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Data end bit error</p>	RW	0
21	DCRC	<p>Data CRC Error</p> <p>This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.</p> <p>Read 0x0: No Error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data CRC error</p> <p>Write 0x1: Status is cleared</p>	RW	0
20	DTO	<p>Data timeout error</p> <p>This bit is set automatically according to the following conditions:</p> <ul style="list-style-type: none"> <li>- busy timeout for R1b, R5b response type</li> <li>- busy timeout after write CRC status</li> <li>- write CRC status timeout</li> <li>- read data timeout</li> </ul> <p>Read 0x0: No error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Time out</p>	RW	0
19	CIE	<p>Command index error</p> <p>This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable in <a href="#">MMCHS_CMD[20]</a> CICE register.</p> <p>Read 0x0: No error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Command index error</p> <p>Write 0x1: Status is cleared</p>	RW	0
18	CEB	<p>Command end bit error</p> <p>This bit is set automatically when detecting a 0 at the end bit position of a command response.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No error.</p> <p>Read 0x1: Command end bit error</p> <p>Write 0x1: Status is cleared</p>	RW	0
17	CCRC	<p>Command CRC Error</p> <p>This bit is set automatically when there is a CRC7 error in the command response depending on the enable in <a href="#">MMCHS_CMD[19]</a> CCCE register.</p> <p>Read 0x0: No Error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Command CRC error</p>	RW	0

Bits	Field Name	Description	Type	Reset
16	CTO	<p>Command Timeout Error</p> <p>This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No error</p> <p>Read 0x1: Time Out</p> <p>Write 0x1: Status is cleared</p>	RW	0
15	ERRI	<p>Error Interrupt</p> <p>If any of the bits in the Error Interrupt Status register (<a href="#">MMCHS_STAT</a>[24:15]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.</p> <p>Read 0x0: No Interrupt.</p> <p>Read 0x1: Error interrupt event(s) occurred</p>	R	0
14:11	RESERVED	<p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p>	R	0x0
10	BSR	<p>Boot status received interrupt</p> <p>This bit is set automatically when <a href="#">MMCHS_CON</a>[18] <a href="#">BOOT_CF0</a> is set 0x0 or 0x1 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No Interrupt.</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Boot status received interrupt.</p>	RW	0
9	OBI	<p>Out-Of-Band interrupt</p> <p>This bit is set automatically when <a href="#">MMCHS_CON</a>[14] <a href="#">OBIE</a> is set and an Out-of-Band interrupt occurs on OBI pin.</p> <p>The interrupt detection depends on polarity controlled by <a href="#">MMCHS_CON</a>[13] <a href="#">OBIP</a>.</p> <p>This interrupt is only useful for MMC card.</p> <p>The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.</p> <p>Read 0x0: No Out-Of-Band interrupt.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Interrupt Out-Of-Band occurs</p> <p>Write 0x1: Status is cleared</p>	RW	0
8	CIRQ	<p>Card interrupt</p> <p>This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle.</p> <p>In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end. All modes above are fully exclusive.</p> <p>The controller interrupt must be clear by setting <a href="#">MMCHS_IE</a>[8] <a href="#">CIRQ_ENABLE</a> to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as <a href="#">MMCHS_IE</a>[8] <a href="#">CIRQ_ENABLE</a> is set to 1. Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt</p> <p>Read 0x1: Generate card interrupt</p>	R	0

Bits	Field Name	Description	Type	Reset
7	CREM	<p>Card removal</p> <p>This bit is set automatically when <a href="#">MMCHS_PSTATE[16]</a> CINS changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (<a href="#">MMCHS_PSTATE[16]</a> CINS).</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: Card state stable or Debouncing</p> <p>Read 0x1: Card removed</p> <p>Write 0x1: Status is cleared</p>	RW	0
6	CINS	<p>Card insertion</p> <p>This bit is set automatically when <a href="#">MMCHS_PSTATE[16]</a> changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (<a href="#">MMCHS_PSTATE[16]</a> CINS).</p> <p>Read 0x0: Card state stable or debouncing</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Card inserted</p>	RW	0
5	BRR	<p>Buffer read ready</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by <a href="#">MMCHS_BLK[11:0]</a> BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
4	BWR	<p>Buffer write ready</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by <a href="#">MMCHS_BLK[11:0]</a> BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
3	DMA	<p>DMA interrupt :</p> <p>This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.</p> <p>Read 0x0: Dma interrupt detected</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: No dma interrupt</p>	RW	0

Bits	Field Name	Description	Type	Reset
2	BGE	<p>Block gap event</p> <p>When a stop at block gap is requested (<a href="#">MMCHS_HCTL[16] SBGR</a>), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the DAT Line active status (<a href="#">MMCHS_PSTATE[2] DLA</a>) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Transaction stopped at block gap</p>	RW	0
1	TC	<p>Transfer completed</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (<a href="#">MMCHS_HCTL[16] SBGR</a>).</p> <p>In Read mode:</p> <p>This bit is automatically set on completion of a read transfer (<a href="#">MMCHS_PSTATE[9] RTA</a>).</p> <p>In write mode:</p> <p>This bit is set automatically on completion of the DAT line use (<a href="#">MMCHS_PSTATE[2] DLA</a>).</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No transfer complete</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Data transfer complete</p>	RW	0
0	CC	<p>Command complete</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (<a href="#">MMCHS_PSTATE[0] CMDI</a>)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command.</p> <p>A command timeout error (<a href="#">MMCHS_STAT[16] CTO</a>) has higher priority than command complete (<a href="#">MMCHS_STAT[0] CC</a>).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No Command complete</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Command complete</p>	RW	0

<b>Address Offset</b>	0x0000 023C		
<b>Physical Address</b>	0x4809 C23C 0x480B 423C 0x480A D23C 0x480D 123C 0x480D 523C	<b>Instance</b>	MMCHS1 MMCHS2 MMCHS3 MMCHS4 MMCHS5
<b>Description</b>	Auto CMD12 Error Status Register The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this <b>MMCHS_AC12</b> register when an Auto CMD12 Error interrupt occurs. This register is valid only when Auto CMD12 is enabled ( <b>MMCHS_CMD</b> [2] ACEN) and Auto CMD12Error ( <b>MMCHS_STAT</b> [24] ACE) is set to 1. Note: These bits are automatically reset when starting a new adtc command with data.		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																CNI	RESERVED	ACIE	ACEB	ACCE	ACTO	ACNE									

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored.	R	0x000000
7	CNI	Command not issue by Auto CMD12 error If this bit is set to 1, it means that pending command is not executed due to Auto CMD12 error : ACEB, ACCE, ACTO or ACNE.  Read 0x0: Not error Read 0x1: Command not issued	R	0
6:5	RESERVED	Reserved These bits are initialized to zero, and writes to them are ignored.	R	0x0

Bits	Field Name	Description	Type	Reset
4	ACIE	Auto CMD12 index error This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted. This bit depends on the command index check enable ( <a href="#">MMCHS_CMD[20] CICE</a> ). Read 0x0: No error Read 0x1: Auto CMD12 Index Error	R	0
3	ACEB	Auto CMD12 end bit error This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response. Read 0x0: No error Read 0x1: AutoCMD12 End bit Error	R	0
2	ACCE	Auto CMD12 CRC error This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in <a href="#">MMCHS_CMD[19] CCCE</a> register. Read 0x0: No error Read 0x1: Auto CMD12 CRC Error	R	0
1	ACTO	Auto CMD12 timeout error This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command. Read 0x0: No error Read 0x1: Auto CMD12 Time Out	R	0
0	ACNE	Auto CMD12 not executed This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before Auto CMD12 starts. Read 0x0: Auto CMD12 Executed Read 0x1: Auto CMD12 Not Executed	R	0

<b>Address Offset</b>	0x0000 0240		
<b>Physical Address</b>	0x4809 C240 0x480B 4240 0x480A D240 0x480D 1240 0x480D 5240	<b>Instance</b>	MMCHS1 MMCHS2 MMCHS3 MMCHS4 MMCHS5
<b>Description</b>	Capabilities register This register lists the capabilities of the MMC/SD/SDIO host controller.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED	RESERVED	RESERVED	BIT64	RESERVED	VS18	VS30	VS33	SRS	DS	HSS	RESERVED	AD2S	RESERVED	MBL	RESERVED										TCU	RESERVED						TCF

Bits	Field Name	Description	Type	Reset
31:29	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x0
28	BIT64	64-bit system bus support: Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus.  Read 0x0: 32-bit system bus address Read 0x1: 64-bit system bus address	R	0
27	RESERVED		R	0
26	VS18	Voltage support 1.8 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal)  Write 0x0: 1.8 V not supported Read 0x0: 1.8 V not supported Read 0x1: 1.8 V supported Write 0x1: 1.8 V supported	RW	0
25	VS30	Voltage support 3.0 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal)  Read 0x0: 3.0 V not supported Write 0x0: 3.0 V not supported Write 0x1: 3.0 V supported Read 0x1: 3.0 V supported	RW	0
24	VS33	Voltage support 3.3 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal)  Read 0x0: 3.3 V not supported Write 0x0: 3.3 V not supported Write 0x1: 3.3 V supported Read 0x1: 3.3 V supported	RW	0
23	SRS	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports suspend/resume functionality.  Read 0x0: The host controller does not suspend/resume functionality. Read 0x1: The host controller supports suspend/resume functionality.	R	1
22	DS	DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly.  Read 0x0: DMA not supported Read 0x1: DMA supported	R	1
21	HSS	High-speed support This bit indicates that the host controller supports high-speed operations and can supply an up-to maximum card frequency.  Read 0x0: High speed not supported Read 0x1: High speed supported	R	1

Bits	Field Name	Description	Type	Reset
20	RESERVED	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
19	AD2S	ADMA2 support: This bit indicates whether the host controller is capable of using ADMA2. It depends on setting of generic parameter <a href="#">MMCHS_HL_HWINFO[0] MADMA_EN</a> Read 0x0: ADMA2 not supported Read 0x1: ADMA2 supported	R	1
18	RESERVED	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
17:16	MBL	Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512- byte and 1024-byte block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes	R	0x1
15:14	RESERVED	Reserved. These bits are initialized to zero, and writes to them are ignored.	R	0x0
13:8	BCF	Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method.	R	0x00
7	TCU	Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error ( <a href="#">MMCHS_STAT[20] DTO</a> ). Read 0x0: kHz Read 0x1: MHz	R	1
6	RESERVED	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
5:0	TCF	Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error ( <a href="#">MMCHS_STAT[20] DTO</a> ). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register.	R	0x00

## **General-Purpose Interface**

---

---

---

This chapter describes the general-purpose interface on the device.

<b>Topic</b>	<b>Page</b>
<b>25.1 General-Purpose Interface Overview .....</b>	<b>5635</b>
<b>25.2 General-Purpose Interface Environment .....</b>	<b>5638</b>
<b>25.3 General-Purpose Interface Integration .....</b>	<b>5643</b>
<b>25.4 General-Purpose Interface Functional Description .....</b>	<b>5647</b>
<b>25.5 General-Purpose Interface Programming Guide .....</b>	<b>5663</b>
<b>25.6 General-Purpose Interface Register Manual .....</b>	<b>5665</b>

## 25.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 × 32) pins.

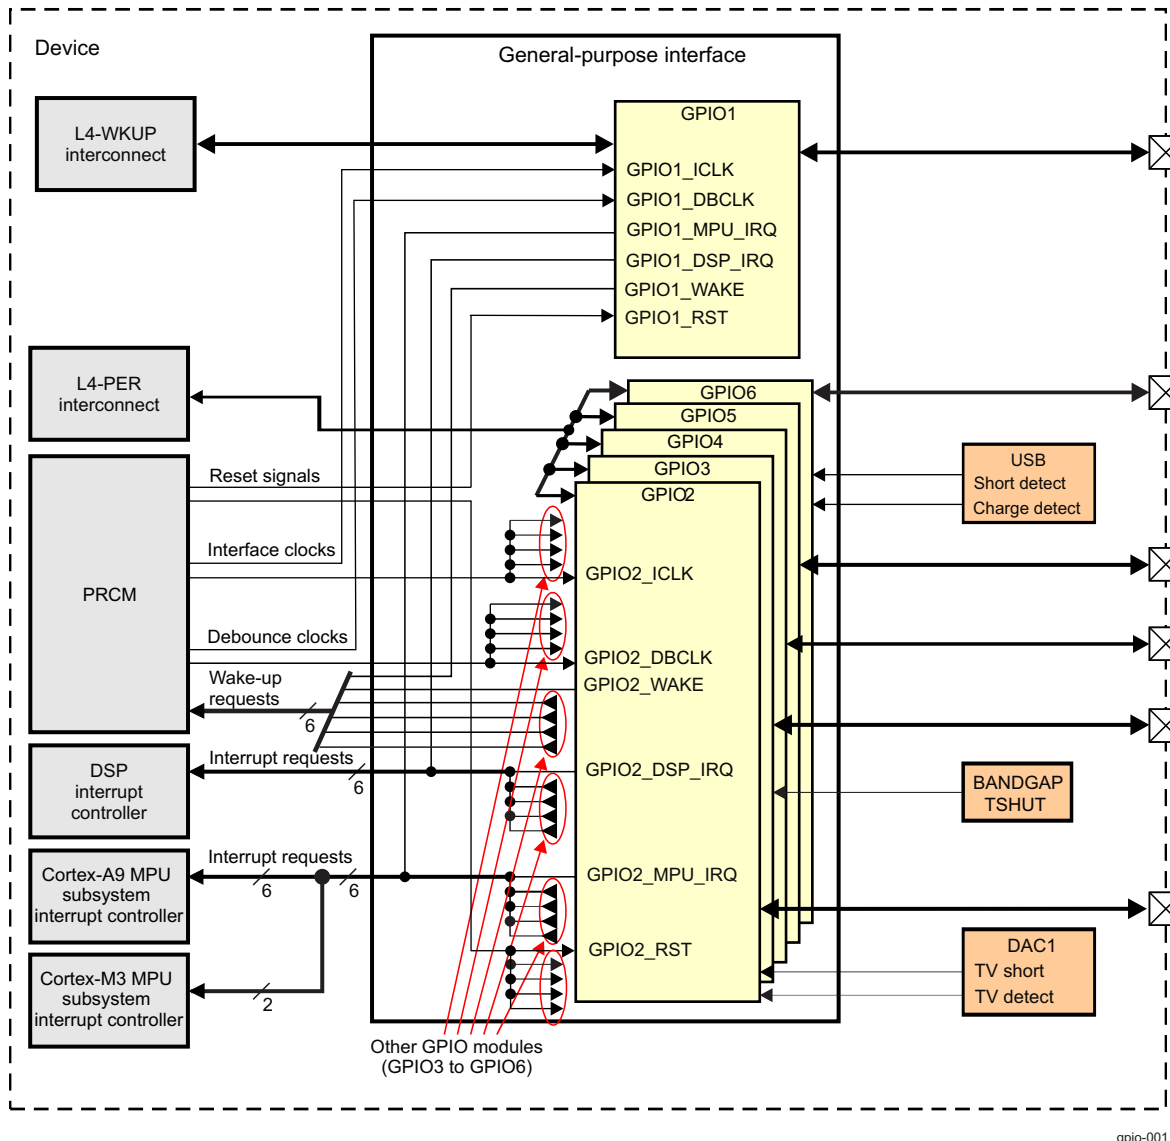

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/pulldown control, open-drain feature). For more information, see [Section 18.4.8](#), *Pad Functional Multiplexing and Configuration*, in [Chapter 18](#), *Control Module*.

[Figure 25-1](#) is an overview of the general-purpose interface.

Figure 25-1. General-Purpose Interface Overview

The GPIOs include the following global features:

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the digital signal processor (DSP) and microprocessor unit (MPU) Cortex™-A9 and Cortex™-M3 subsystems. One of these interrupts is mapped on the DSP subsystem interrupt controller (INTC) and the other on the MPU Cortex-A9 and Cortex-M3 subsystem INTCs.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per each GPIO instance).

Each GPIO produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIOs has the following features:

- The GPIOi.GPIO\_OE register controls the output capability for each pin.

- The output line level reflects the value written in the GPIOi.GPIO\_DATAOUT register through the L4 interconnect.
- The input line can be fed to the GPIO through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO, up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO\_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO\_DATAOUT
- GPIOi.GPIO\_IRQSTATUS\_SET\_0
- GPIOi.GPIO\_IRQSTATUS\_SET\_1
- GPIOi.GPIO\_IRQSTATUS\_CLR\_0
- GPIOi.GPIO\_IRQSTATUS\_CLR\_1

For these registers, the modules implement the set-and-clear protocol register update (see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

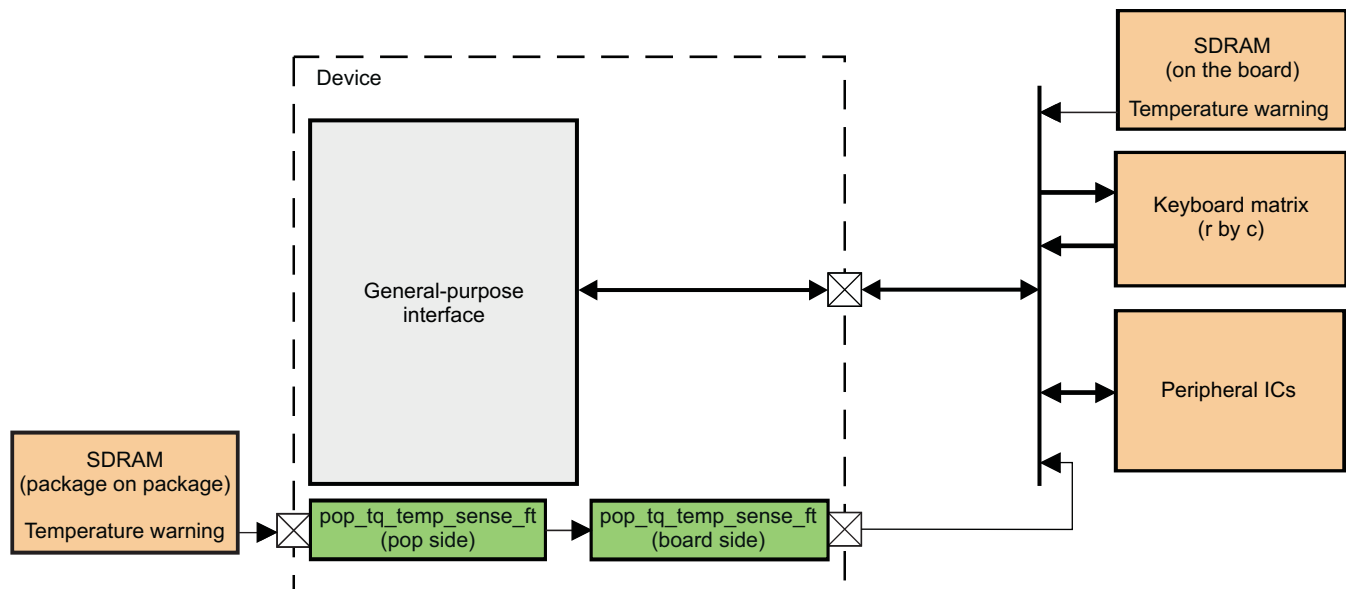

## 25.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, GPIO controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 25-2 shows a typical application using the general-purpose interface.

**Figure 25-2. General-Purpose Interface Typical Application**

gpio-002

**NOTE:** Most memories provide a temperature sensor to control the autorefresh duty cycle. The device monitors the temperature of the external memory using the `pop_tq_temp_sense_ft` ball and a GPIO input. To do this, `pop_tq_temp_sense_ft` is connected to a GPIO through the customer board. This feature is application-dependent.

### CAUTION

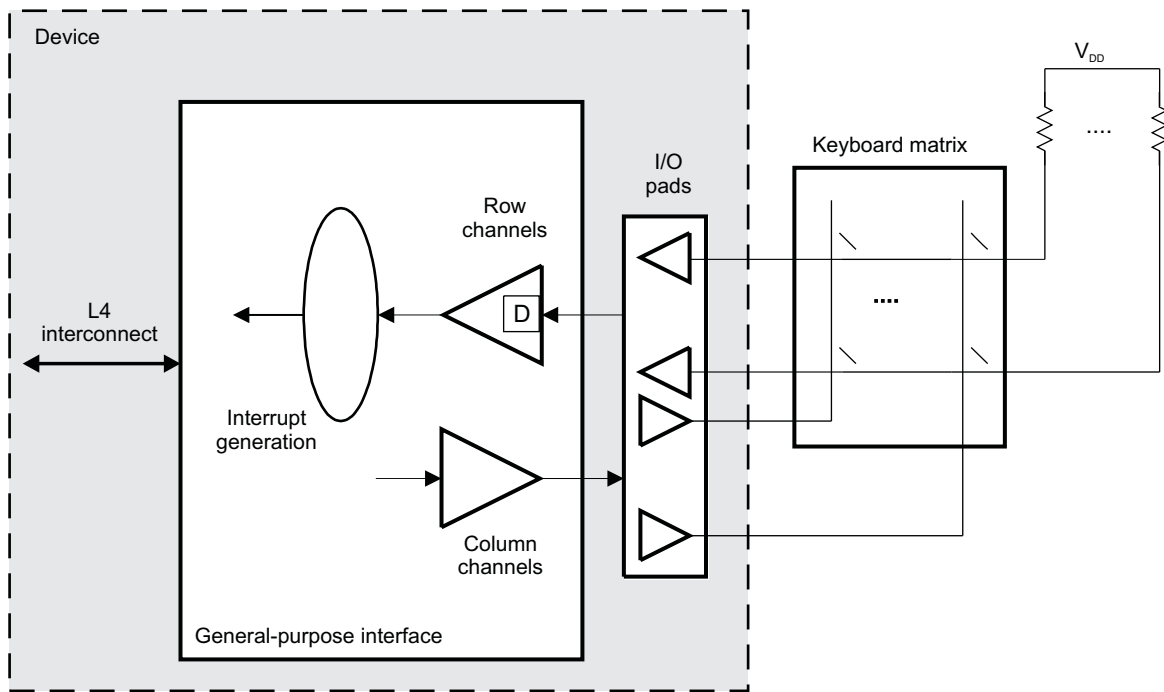

Because of buffer strength, an external serial resistor must be connected to the balls where `gpio_120` through `gpio_129` are muxed with MMC signals.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

### 25.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix ( $r \times c$ ). Figure 25-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 25-3. General-Purpose Interface Used as a Keyboard Interface

gpio-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 25.4.6, *Interrupt and Wake-Up Requests*).

When the keyboard interrupt is received, the processor (MPU and/or DSP subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

### 25.2.2 General-Purpose Interface Signals

Table 25-1 describes the module signals.

Table 25-1. I/O Description

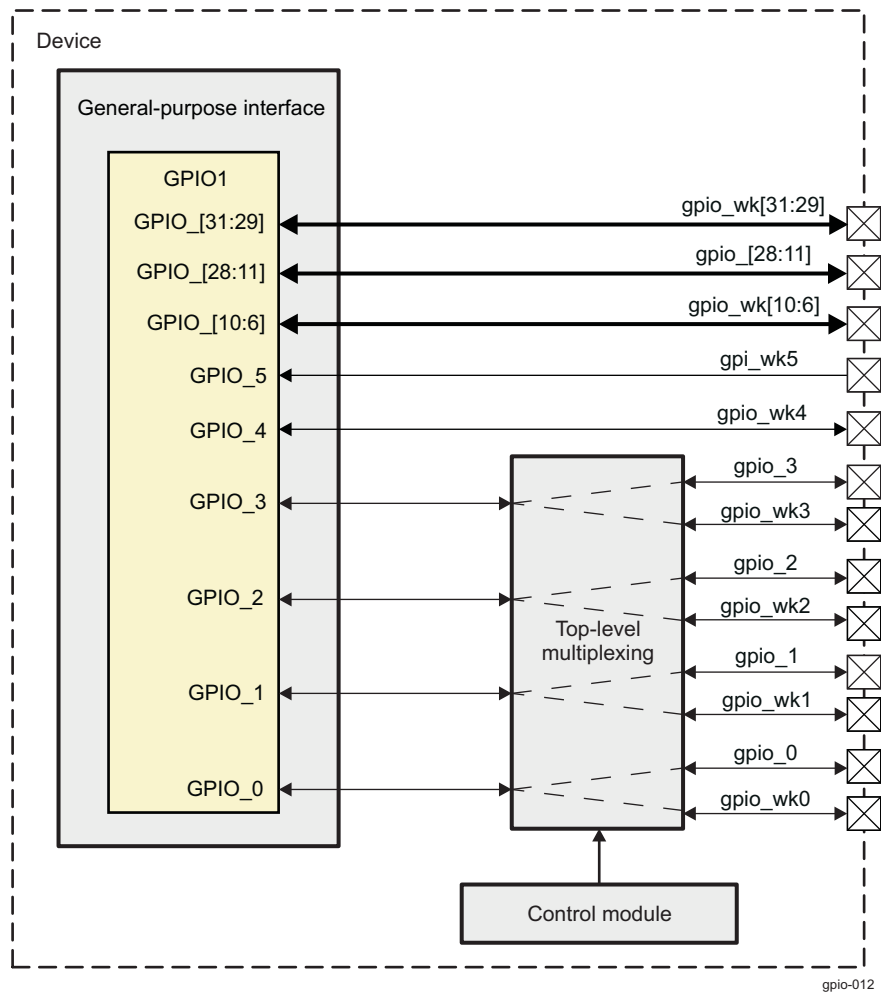

Signal	I/O <sup>(1)</sup>	Description	Reset Value
gpio_[1:0]	I/O	GPIO	HiZ
gpio_wk[1:0]	I/O	GPIO (direct wake-up path). Shares the same GPIO channels with gpio_[1:0].	HiZ
gpio_[3:2]	I/O	GPIO	HiZ
gpio_wk[3:2]	I/O	GPIO (direct wake-up path). Shares the same GPIO channels with gpio_[3:2].	HiZ
gpio_wk4	I/O	GPIO (direct wake-up path)	HiZ
gpi_wk5	I	GPIO input only (direct wake-up path)	HiZ
gpio_wk[10:6]	I/O	GPIO (direct wake-up path)	HiZ
gpio_[28:11]	I/O	GPIO	HiZ

<sup>(1)</sup> I = Input; O = Output

**Table 25-1. I/O Description (continued)**

Signal	I/O <sup>(1)</sup>	Description	Reset Value
gpio_wk[31:29]	I/O	GPIO (direct wake-up path)	HiZ
gpio_[56:32]	I/O	GPIO	HiZ
gpio_[66:59]	I/O	GPIO	HiZ
gpi_[80:67]	I	GPIO inputs only	HiZ
gpio_[178:81]	I/O	GPIO	HiZ
gpio_[191:181]	I/O	GPIO	HiZ

Figure 25-4 shows the signal connections of GPIO1.

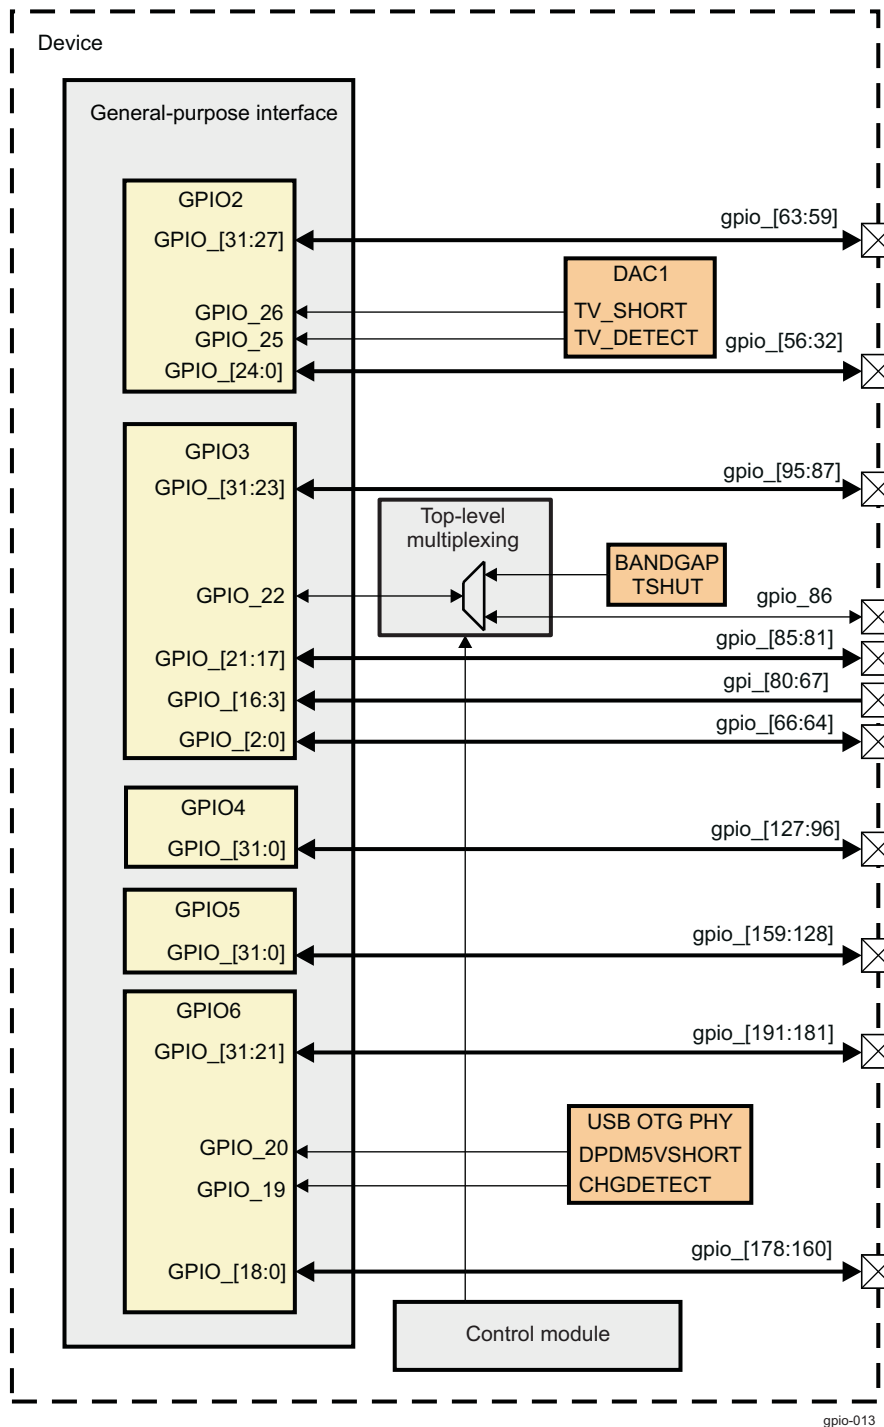

**Figure 25-4. GPIO1 Signal Connections**

- NOTE:** Users must not use a GPIO channel through two device pads simultaneously. Channels that can be mapped on two different device pads are:
- GPIO[3:0] of the GPIO1 module (signals gpio\_[3:0] or gpio\_wk[3:0]; each can be routed to a different device pad). See [Figure 25-4](#).
  - GPIO[8:4] of the GPIO4 module (signals gpio\_[104:100]; each can be routed to two different device pads)

Therefore, appropriate configuration must be done through the pad configuration registers. See [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

---

[Figure 25-5](#) shows the signal connections of GPIO2 through GPIO6.

**Figure 25-5. GPIO2 Through GPIO6 Signal Connections**

**NOTE:** The GPIO<sub>22</sub> channel of the GPIO3 module receives a thermal shutdown (TSHUT) signal from the BANDGAP module whenever pad mux mode is not set to 3 (gpio<sub>86</sub> signal selected). See [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

**NOTE:** For more information about the signals and channel descriptions of GPIO1 through GPIO6, see [Section 25.4.7, General-Purpose Interface Channels Description](#).

---

**NOTE:** For more information about GPIO signal multiplexing, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

### 25.3 General-Purpose Interface Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

[Figure 25-6](#) shows this module integration.

Figure 25-6. GPIO Integration

gpio-004

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 25-2 through Table 25-4 summarize the integration of the module in the device.

**Table 25-2. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
GPIO1	PD_WKUP	L4-WKUP
GPIOi, where i = 2 to 6	PD_L4_PER	L4-PER

**Table 25-3. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
GPIO1	GPIO1_ICLK	WKUP_L4_ICLK	PRCM	GPIO interface clock
GPIO1	GPIO1_DBCLK	WKUP_32K_FCLK	PRCM	GPIO debounce clock
GPIO2	GPIO2_ICLK	PER_L4_ICLK	PRCM	GPIO interface clock
GPIO2	GPIO2_DBCLK	PER_32K_FCLK	PRCM	GPIO debounce clock
GPIO3	GPIO3_ICLK	PER_L4_ICLK	PRCM	GPIO interface clock
GPIO3	GPIO3_DBCLK	PER_32K_FCLK	PRCM	GPIO debounce clock
GPIO4	GPIO4_ICLK	PER_L4_ICLK	PRCM	GPIO interface clock
GPIO4	GPIO4_DBCLK	PER_32K_FCLK	PRCM	GPIO debounce clock
GPIO5	GPIO5_ICLK	PER_L4_ICLK	PRCM	GPIO interface clock
GPIO5	GPIO5_DBCLK	PER_32K_FCLK	PRCM	GPIO debounce clock

## 25.4 General-Purpose Interface Functional Description

### 25.4.1 General-Purpose Interface Block Diagram

Figure 25-7 shows the general-purpose interface.

Figure 25-7. General-Purpose Interface Description

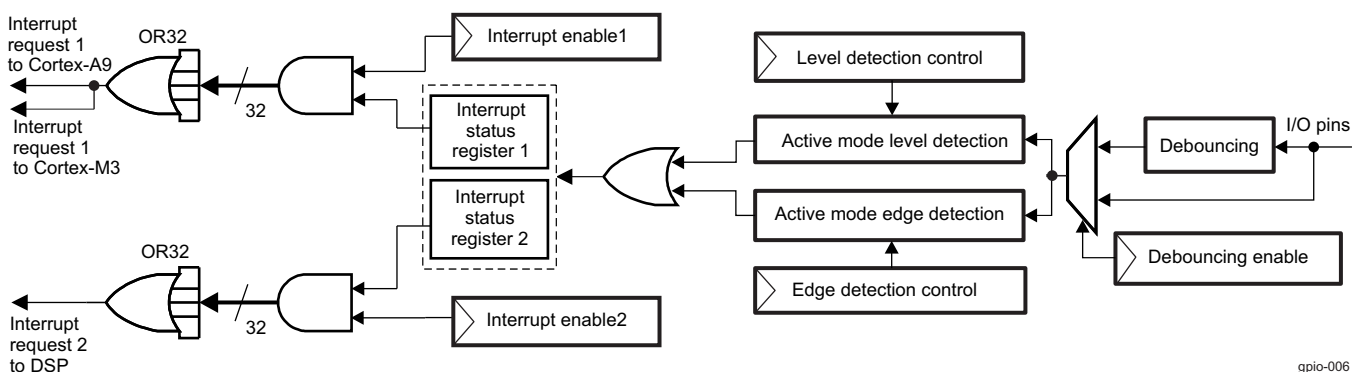

gpio-005

Figure 25-7 shows the details of the GPIOs in the general-purpose interface block diagram, including their configuration registers and main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0, and GPIOi.GPIO\_IRQSTATUS\_CLR\_1). See Figure 25-8.

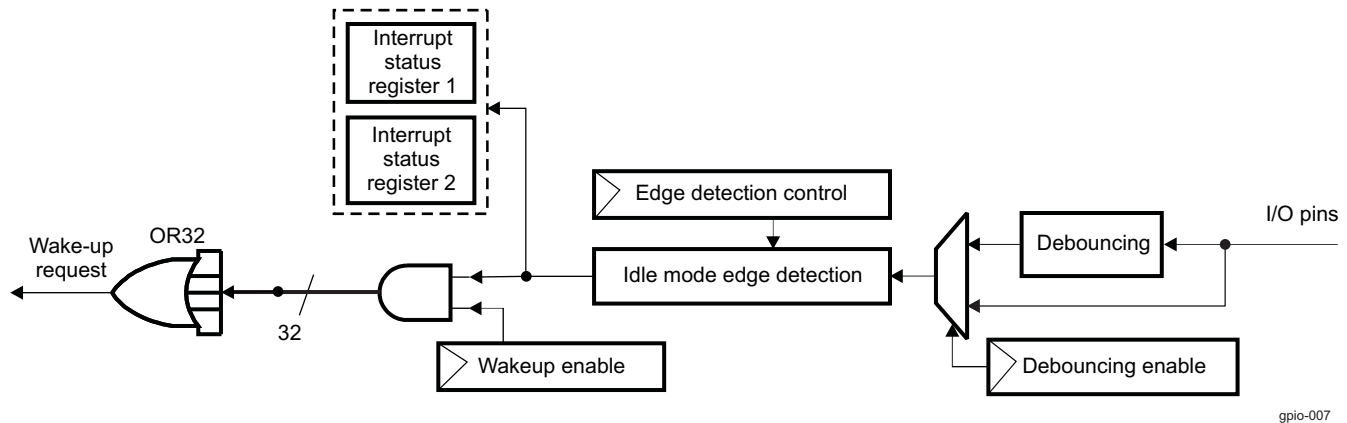

Figure 25-8. Synchronous Path

gpio-006

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 25-9.

Figure 25-9. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode)

gpio-007

## 25.4.2 General-Purpose Interface Interrupt and Wake-Up Features

### 25.4.2.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per each GPIO instance). The 12 interrupt signals are GPIOi\_MPU\_IRQ (used by the MPU) and GPIOi\_DSP\_IRQ (used by the DSP subsystem), where  $i = 1, 2, 3, 4, 5, \text{ or } 6$ .

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the DSP subsystem on one side and by the MPU subsystems on the other side. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0, or GPIOi.GPIO\_IRQSTATUS\_CLR\_1) and interrupt status registers (GPIOi.GPIO\_IRQSTATUS\_0 or GPIOi.GPIO\_IRQSTATUS\_1). The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see [Section 25.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see [Section 25.4.5.2.4, Module Power Saving](#)). When an event matches the programmed settings (see [Section 25.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)), the corresponding bit in the interrupt status register is set to 1 and, on the following interface clock cycle, interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals  $N$  times the interface clock period (see [Section 25.4.5.2.4, Module Power Saving](#)). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles + one interface clock cycle when the debounce feature is not used.

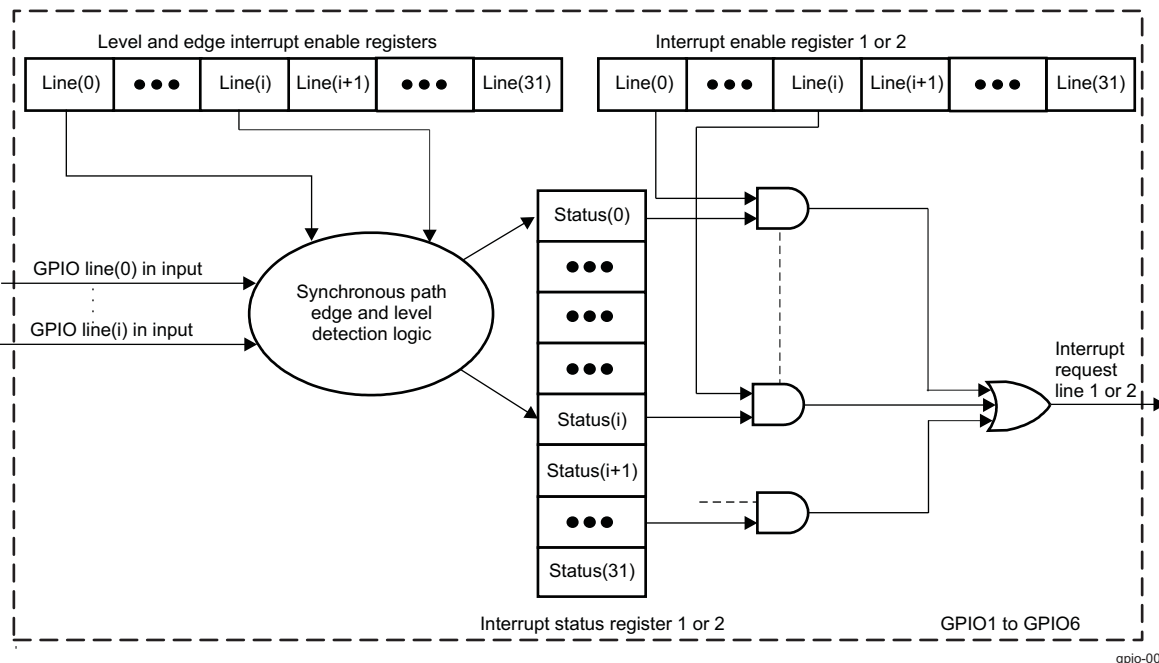

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO\_DEBOUNCINGTIME) (see [Section 25.4.3, General-Purpose Interface Clock Configuration](#)) and is less than three internally gated interface clock cycles plus two interface clock cycles plus GPIOi.GPIO\_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the Cortex-A9 MPU and Cortex-M3 MPU subsystems.

Synchronous interrupt request line 2 is mapped on the DSP INTC.

Figure 25-10 is an overview of the interrupt request generation.

Figure 25-10. Interrupt Request Generation

### 25.4.2.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per each GPIO module. The wake-up-enable registers (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO\_IRQSTATUS\_0 and GPIOi.GPIO\_IRQSTATUS\_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 25.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi\_SWAKEUP, where i = 1, 2, 3, 4, 5, or 6), if the wake-up-enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO\_IRQSTATUS\_0 and GPIOi.GPIO\_IRQSTATUS\_1). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0 and GPIOi.GPIO\_IRQSTATUS\_CLR\_1).

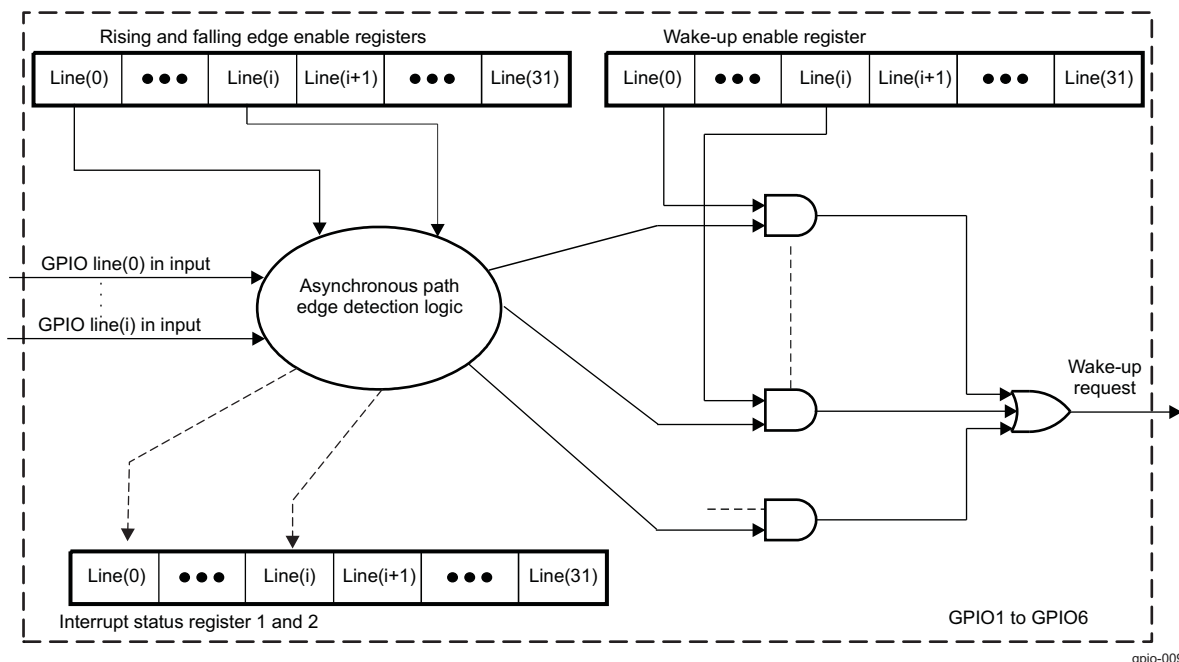

**NOTE:** When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP bit enables or disables the GPIO wake-up feature globally. If the bit is set to 0, the wake-up-enable registers (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1) have no effect.

Figure 25-11 is an overview of the wake-up request generation.

**Figure 25-11. Wake-Up Request Generation**

gpio-009

### 25.4.2.3 Wake-Up Event Conditions During Transition To and From IDLE State

Figure 25-12 shows the wake-up event conditions.

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of the SLEEPTRANS state. During this period a synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

In phase C, only the asynchronous path is enabled. A wake-up request (see [Section 25.4.2.2, Asynchronous Path: Wake-Up Request Generation](#)) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

In phase D, eight OCP clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

Figure 25-12. Wake-Up Event Conditions

gpio-014

#### 25.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or DSP subsystem in the device) receives an interrupt request issued by the GPIO, it reads the corresponding interrupt status register (GPIOi.GPIO\_IRQSTATUS\_0 or GPIOi.GPIO\_IRQSTATUS\_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the software resets the status bit and releases the interrupt line by setting the corresponding bit of the interrupt status register to 1. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

---

**NOTE:** The status bit must be reset to re-enter idle mode.

---

### 25.4.3 General-Purpose Interface Clock Configuration

#### 25.4.3.1 Clocking

Each GPIO uses two clocks:

- **Debounce clock:** The 32-kHz debounce clock, GPIOi\_DBCLK (where i = 1, 2, 3, 4, 5, or 6, with one debounce clock per module) comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

The debouncing value register (GPIOi.GPIO\_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used (one cycle is 31 μs long).

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO\_DEBOUNCINGTIME[7:0] DEBOUNCVL bit field value + 1) × 31,

where the value of the DEBOUNCVL bit field is from 0 to 255.

For more information, see [Section 3.6.8, CD\\_L4\\_PER\\_Clock Domain](#), and [Section 3.6.4, CD\\_WKUP Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Interface clock:** The interface clock, GPIOi\_ICLK (where i = 1, 2, 3, 4, 5, or 6), comes from the PRCM module and is used throughout the GPIO (except within the debounce cell logic). GPIOi\_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

For more information, see [Section 3.6.8, CD\\_L4\\_PER\\_Clock Domain](#), and [Section 3.6.4, CD\\_WKUP Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 25-3](#) describes the GPIO clocks.

[Table 25-5](#) summarizes the functional clock configuration.

**Table 25-5. Functional Clock Configuration**

Interface Clock	GPIO_CTRL[2:1] GATINGRATIO	Functional Clock
GPIOi_ICLK, where i = 1 to 6	00	GPIOi_ICLK /1, where i = 1 to 6
GPIOi_ICLK, where i = 1 to 6	01	GPIOi_ICLK /2, where i = 1 to 6
GPIOi_ICLK, where i = 1 to 6	10	GPIOi_ICLK /4, where i = 1 to 6
GPIOi_ICLK, where i = 1 to 6	11	GPIOi_ICLK /8, where i = 1 to 6

### 25.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO.

- **Hardware reset:** GPIO2 to GPIO6 are attached to the PER\_RST reset domain. GPIO1 is attached to the WKUP\_RST reset domain.

The hardware reset has a global reset action on the GPIOs of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO, the GPIOi.GPIO\_SYSSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see [Section 3.5.4, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Software reset:** Each GPIO has its own software reset using the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

Setting the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit to 1, (where i = 1, 2, 3, 4, 5, or 6) resets the module. A bit value of 1 remains until the reset completes. When the software reset completes, the GPIOi.GPIO\_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a

hardware reset. The GPIOi.GPIO\_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. This bit is set to 1 when the software reset completes.

## **25.4.5 General-Purpose Interface Power Management**

### **25.4.5.1 Power Domain**

GPIO1 is attached to the WKUP power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. GPIO2 to GPIO6 are attached to the PER power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The PER power domain is not active continuously.

### **25.4.5.2 Power Management**

#### **25.4.5.2.1 Idle Scheme**

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi\_WAKEUP, where i = 1, 2, 3, 4, 5, or 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 25.4.6.2, Wake-Up Request Generation](#)).

#### **25.4.5.2.2 Operating Modes**

The following four operating modes are defined for the modules:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.

- Inactive mode: The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)) through sideband signals (see [Section 25.4.5.2.3, System Power Management and Wakeup](#)).

The disabled mode is set by software through a dedicated configuration bit, GPIOi.GPIO\_CTRL[0] DISABLEMODULE (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

#### **25.4.5.2.3 System Power Management and Wakeup**

The PRCM module can require the GPIOs to be idled for power-saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Section 25.4.6.2, Wake-Up Request Generation](#)): one per GPIO. The general-purpose interface allows the GPIOs to enter idle mode based on the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO:

- Smart-idle mode

When the GPIO is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO\_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no access to the GPIO.GPIO\_DEBOUNCINGTIME register, which is waiting to be synchronized.

Idle acknowledge is then asserted and the module enters into idle-mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs.

- Smart-idle wake-up mode

If the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to switch off the interface clock. Once all internal activity ceases (the DATA INPUT REGISTER completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO\_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters into idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the GPIOi.GPIO\_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see [Section 25.6.2.2, System Configuration Register](#)). When the system is awake, the idle request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the systems wakeup) signals are immediately deasserted, and the asynchronous wake-up request (if existing) is reflected into the synchronous interrupt status registers.

- Force-idle mode

When the GPIO is configured in force-idle mode (the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field = 2b00) and receives an idle request from the PRCM module, the GPIO waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the GPIO is configured in no-idle mode (the GPIOi.GPIO\_SYSCONFIG[4:3] IDLEMODE bit field = 2b01) and receives an idle request from the PRCM module, the GPIO does not go into idle mode and the idle acknowledge is never sent.

---

**NOTE:** For more information about idle modes, see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

---

#### 25.4.5.2.4 Module Power Saving

The GPIO has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the GPIO is not accessed, if the GPIOi.GPIO\_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO\_DATAIN register is not accessed.
- Clock gating for the event detection logic: Each GPIO implements four clock groups used for the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the setting of the edge/level detection register (because the input is 32 bits, four groups

of eight inputs are defined for each GPIO). If a group requires no detection, the corresponding clock is gated.

Grouping the edge/level enable can save the power consumption of the module.

If any of the following registers is set to 0x01 01 01 01, then all clocks are active (power consumption is high). If they are set to 0x00 00 00 FF, then a single clock is active (power saving).

- GPIOi.GPIO\_LEVELDETECT0
- GPIOi.GPIO\_LEVELDETECT1
- GPIOi.GPIO\_RISINGDETECT
- GPIOi.GPIO\_FALLINGDETECT

---

**NOTE:** When the clocks are enabled by writing to the following registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

- GPIOi.GPIO\_LEVELDETECT0
- GPIOi.GPIO\_LEVELDETECT1
- GPIOi.GPIO\_RISINGDETECT
- GPIOi.GPIO\_FALLINGDETECT

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following is recommended:

1. Set the new detection required.
2. Disable the previous setting (if necessary).

In this way, the corresponding clock is not gated and the detection starts immediately.

---

All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO\_CTRL[2:1] GATINGRATIO bit field and can take the values 1 (2b00), 2 (2b01), 4 (2b10), or 8 (2b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO\_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Internal activity in the module is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled through the GPIOi.GPIO\_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the device level. This bit takes precedence over all other internal configuration bits.

Table 25-6 describes the power-management features available for the general-purpose interface module.

---

**NOTE:** For information about source clock gating and a description of sleep/wake-up transitions, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

---

**Table 25-6. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit	Sets the clock gating strategy for the OCP interface block.
Slave idle modes	GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field	Force-idle, no-idle, and smart-idle wake-up-capable modes are available.

**Table 25-6. Local Power-Management Features (continued)**

Feature	Registers	Description
Clock activity	GPIOi.GPIO_CTRL[0] DISABLEMODULE bit field	Enable and disable the module.
Debouncing enable	GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE bit field	Debouncing mode is available.
Global wake-up enable	GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit	This bit enables the wake-up feature at module level.
Wake-up sources enable	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLIN bit field GPIOi.GPIO_IRQWAKEN_1[31:0] INTLIN bit field	This register enables or disables a specific IRQ request source to generate a wake-up signal.

Table 25-7 describes the clock activity settings.

**Table 25-7. Clock Activity Settings**

GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE	Selected Mode	Description	Wake-Up Events
00	Force-idle	The GPIO goes into inactive mode independently of the internal module state, and the Idle acknowledge is never sent.	No
01	No-idle	The GPIO does not go into the idle mode and the idle acknowledge is never sent.	No
10	Smart-idle	The GPIO evaluates its internal capability to switch off the interface clock. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode.	No
11	Smart-idle wake-up	The GPIO evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode.	Yes

## 25.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

### 25.4.6.1 Interrupt Request Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per each GPIO instance).

- Synchronous interrupt request line 1 is mapped on the Cortex-A9 and Cortex-M3 MPU INTCs.
- Synchronous interrupt request line 2 is mapped on the DSP INTC.

Table 25-8 lists the event flags, and their mask, that can cause module interrupts.

**Table 25-8. Events**

Event Flag	Event Mask	Synchronous	Sensitivity	Map to	Description
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLIN	GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLIN	Yes	Edge/level	MA_IRQ_n MM_IRQ_n <sup>(1)</sup>	Corresponds to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLIN	GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLIN	Yes	Edge/level	D_IRQ_n	Corresponds to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLIN	GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLIN	Yes	Edge/level	MA_IRQ_n MM_IRQ_n <sup>(1)</sup>	Corresponds to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLIN	GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLIN	Yes	Edge/level	D_IRQ_n	Corresponds to the second line of interrupt
GPIOi.GPIO_IRQSTATUS_0[31:0] INTLIN	GPIOi.GPIO_IRQWAKEN_0[31:0] INTLIN	No	Edge/level	MA_IRQ_n MM_IRQ_n <sup>(1)</sup>	Corresponds to the first line of interrupt
GPIOi.GPIO_IRQSTATUS_1[31:0] INTLIN	GPIOi.GPIO_IRQWAKEN_1[31:0] INTLIN	No	Edge/level	D_IRQ_n	Corresponds to the second line of interrupt

<sup>(1)</sup> For GPIO1 and GPIO2 only

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0, GPIOi.GPIO\_IRQSTATUS\_SET\_1, GPIOi.GPIO\_IRQSTATUS\_CLR\_0 and GPIOi.GPIO\_IRQSTATUS\_CLR\_1).

- Interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_1)

The interrupt-enable1 (or interrupt-enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt-enable registers are programmed synchronously with the interface clock.

These registers can be accessed with direct read/write operations or using the alternate set-and-clear protocol feature for register update. This feature allows the setting or clearing of explicit bits of these registers with a single write access (see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

- Interrupt status registers (GPIOi.GPIO\_IRQSTATUS\_0 and GPIOi.GPIO\_IRQSTATUS\_1)

The interrupt status1 (or interrupt status2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line2) request (or the wake-up line).

When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt status1 (or interrupt status2) register.

If 0 is written to a bit in this register, the value remains unchanged. The interrupt status1 (or interrupt status2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status2 registers are set when the GPIO is awakened.

#### **CAUTION**

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO\_IRQSTATUS\_0 or GPIOi.GPIO\_IRQSTATUS\_1) must be reset and the interrupt line released (by setting the corresponding bit of the interrupt status register to 1).

Before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO\_IRQSTATUS\_SET\_0 or GPIOi.GPIO\_IRQSTATUS\_SET\_1), the corresponding status bit in the interrupt status register (GPIOi.GPIO\_IRQSTATUS\_0 or GPIOi.GPIO\_IRQSTATUS\_1) must be reset to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

#### **25.4.6.2 Wake-Up Request Generation**

GPIO1 of the general-purpose interface is attached to the WKUP power domain (see , *Power Management*, in [Chapter 3, Power, Reset, and Clock Management](#)) and can wake up the system.

---

**NOTE:** GPIO2 to GPIO6 belong to the PER power domain and thus their wake-up capabilities are operational only when the PER power domain is active.

---

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO following the expected transition(s) (based on register programming). Each GPIO generates a wake-up signal to the PRCM module.

---

**NOTE:** Only gpio\_wk[10:0] and gpio\_wk[31:29] can be used to generate a direct wake-up event.

---

The asynchronous wake-up request line is active based on the GPIOi.GPIO\_IRQWAKEN\_0 and GPIO\_IRQWAKEN\_1 wake-up-enable registers (where i = 1, 2, 3, 4, 5, or 6).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

**NOTE:** There must be a correlation between the wake-up enable and interrupt-enable registers. If a GPIO pin has a wake-up configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future idle request.

Table 25-9 lists the mapping of the wake-up signals.

**Table 25-9. Wake-Up Signals**

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module.

### 25.4.7 General-Purpose Interface Channel Description

Table 25-10 describes the GPIO channels.

**Table 25-10. GPIO Channel Description**

Channel Number	Type <sup>(1)</sup>	Mapping	Wake-Up Feature	Comments
<b>GPIO1</b>				
[31]	I/O	gpio_wk31	Yes	Wake-up path
[30]	I/O	gpio_wk30	Yes	Wake-up path
[29]	I/O	gpio_wk29	Yes	Wake-up path
[28:11]	I/O	gpio_[28:11]	Yes	GPIO
[10:6]	I/O	gpio_wk[10:6]	Yes	Wake-up path
[5]	I	gpi_wk5	Yes	Wake-up path
[4]	I/O	gpio_wk4	Yes	Wake-up path
[3:2]	I/O	gpio_[3:2]	Yes	GPIO
	I/O	gpio_wk[3:2]	Yes	Wake-up path
[1:0]	I/O	gpio_[1:0]	Yes	GPIO
	I/O	gpio_wk[1:0]	Yes	Wake-up path
<b>GPIO2</b>				
[31:27]	I/O	gpio_[63:59]	Yes <sup>(2)</sup>	GPIO
[26] <sup>(3)</sup>	I	TV_SHORT	Yes <sup>(2)</sup>	Internal TV short signal from video DAC1
[25] <sup>(3)</sup>	I	TV_DETECT	Yes <sup>(2)</sup>	Internal TV detection signal from video DAC1
[24:0]	I/O	gpio_[56:32]	Yes <sup>(2)</sup>	GPIO
<b>GPIO3</b>				
[31:17]	I/O	gpio_[95:81]	Yes <sup>(2)</sup>	GPIO
[22] <sup>(4)</sup>	I/O	gpio_86	Yes <sup>(2)</sup>	GPIO
	I	TSHUT	Yes <sup>(2)</sup>	Bandgap internal TSHUT
[21:17]	I/O	gpio_[85:81]	Yes <sup>(2)</sup>	GPIO
[16:3]	I	gpi_[80:67]	Yes <sup>(2)</sup>	GPIO inputs only

<sup>(1)</sup> I = Input; O = Output

<sup>(2)</sup> Only when the PER power domain is active

<sup>(3)</sup> The GPIO channel is not available on device pads. Reserved for internal use only (see the Comments column).

<sup>(4)</sup> The GPIO channel provides additional internal functionality (see the Comments column), besides its GPIO capabilities, when it is not connected to a pad of the device. That is, the corresponding pad is configured in a mode different from multiplexing mode 3. For more information about pad configuration and multiplexing, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

**Table 25-10. GPIO Channel Description (continued)**

Channel Number	Type <sup>(1)</sup>	Mapping	Wake-Up Feature	Comments
[2:0]	I/O	gpio_[66:64]	Yes <sup>(2)</sup>	GPIO
<b>GPIO4</b>				
[31:0]	I/O	gpio_[127:96]	Yes <sup>(2)</sup>	GPIO
<b>GPIO5</b>				
[31:0]	I/O	gpio_[159:128]	Yes <sup>(2)</sup>	GPIO
<b>GPIO6</b>

[20] <sup>(3)</sup>	I	DPDM5VSHORT	Yes <sup>(2)</sup>	USB OTG PHY short detect (DPDM5VSHORT)
[19] <sup>(3)</sup>	I	CHGDETECT	Yes <sup>(2)</sup>	USB OTG PHY charge detect (CHGDETECT)
[18:15]	I/O	gpio_[178:175]	Yes <sup>(2)</sup>	GPIO
[14:0]	I/O	gpio_[174:160]	Yes <sup>(2)</sup>	GPIO

---

**NOTE:** The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is high during normal operation and goes low during a thermal shutdown event. When channel 22 of the GPIO3 is not connected to a ball of the device (the corresponding pin is configured in a mode different from configuration mode 4; see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#), for more information about pin configuration), TSHUT is connected to channel 22 of GPIO3. The channel must be configured correctly so that it can generate an interrupt when a high-to-low transition occurs on TSHUT.

---

---

**NOTE:** Channels 20 and 19 of GPIO6 are internally connected inside the device to the short detection (DPDM5VSHORT) and charger detection (CHGDETECT) outputs, respectively, of the USB OTG PHY module. This allows interrupt generation on the corresponding GPIO channel, if either of the mentioned events occurs.

---

### 25.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO\_OE) controls the output/input capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO\_OE register), the value of the corresponding bit in the GPIOi.GPIO\_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set-output data register (GPIOi.GPIO\_SETDATAOUT) or to the clear-output data register (GPIOi.GPIO\_CLEARDATAOUT) address (see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#)). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up-enable (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1) and the interrupt-enable (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_1) registers.

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO\_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO\_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin

as an input, the application must properly configure the wake-up enable (GPIOi.GPIO\_IRQWAKEN\_0 and GPIOi.GPIO\_IRQWAKEN\_1) and the interrupt-enable (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_0) registers to the interrupt and wake-up feature as needed. For using the alternate set-and-clear protocol, see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#).

## 25.4.9 General-Purpose Interface Set-and-Clear Protocol

### 25.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO\_DATAOUT
- GPIOi.GPIO\_IRQSTATUS\_CLR\_0
- GPIOi.GPIO\_IRQSTATUS\_CLR\_1
- GPIOi.GPIO\_IRQSTATUS\_SET\_0
- GPIOi.GPIO\_IRQSTATUS\_SET\_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

### 25.4.9.2 Clear Instruction

#### 25.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_CLR\_0 and GPIOi.GPIO\_IRQSTATUS\_CLR\_1).  
A write operation in the GPIO\_IRQSTATUS\_CLR\_0 (or GPIO\_IRQSTATUS\_CLR\_1) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.  
A read of the clear interrupt-enable0 (or enable1) register returns the value of the GPIO\_IRQSTATUS\_CLR\_0 (or GPIO\_IRQSTATUS\_CLR\_1) register.
- Clear data-output register (GPIOi.GPIO\_CLEARDATAOUT).  
A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.  
A read of the clear data-output register returns the value of the data-output register.

#### 25.4.9.2.2 Clear Instruction Example

Assume the data-output register (or one of the interrupt/wake-up-enable register) contains the binary value, 0b0000 0001 0000 0001, and bit 0 is to be clear.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt/wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt/wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

**NOTE:** Although the general-purpose interface registers are 32 bits wide, only the least-significant 16 bits are represented in this example.

Figure 25-13 shows an example of a clear instruction.

Figure 25-13. GPIO\_CLEARDATAOUT Register Example

### 25.4.9.3 Set Instruction

#### 25.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO\_IRQSTATUS\_SET\_0 and GPIOi.GPIO\_IRQSTATUS\_SET\_1).  
A write operation in the GPIOi.GPIO\_IRQSTATUS\_SET\_0 (or GPIOi.GPIO\_IRQSTATUS\_SET\_1) register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.  
A read of the set interrupt-enable0 (or enable1) register returns the value of the interrupt GPIOi.GPIO\_IRQSTATUS\_SET\_0 (or GPIOi.GPIO\_IRQSTATUS\_SET\_1) register.
- Set data-output register (GPIOi.GPIO\_SETDATAOUT).  
A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.  
A read of the set data-output register returns the value of the data-output register.

### 25.4.9.3.2 Set Instruction Example

Assume the interrupt-enable1 (or enable2) register (or the data-output register) contains the binary value, 0b0000 0001 0000 0000, and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable 1 (or enable2) register (or at the address of the set data-output register). After this write operation, a reading of the interrupt-enable1 (or enable2) register (or the data-output register) returns 0b1000 0001 0000 1110; bits 15, 3, 2, and 1 are set.

---

**NOTE:** Although the general-purpose interface registers are 32 bits wide, only the least-significant 16 bits are represented in this example.

---

Figure 25-14 shows an example of a set instruction.

**Figure 25-14. Write in GPIO\_IRQSTATUS\_SET\_0 Register Example**

gpio-011

The set wake-up-enable register offers the same feature with the wake-up-enable register.

## 25.5 General-Purpose Interface Programming Guide

### 25.5.1 General-Purpose Interface Low-Level Programming Models

#### 25.5.1.1 Global Initialization

##### 25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the general-purpose interface. For more information, see [Section 25.3, General-Purpose Interface Integration](#), and [Section 25.2, General-Purpose Interface Environment](#).

**Table 25-11. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. For more information about the module configuration, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Control module	Module-specific pad muxing must be set in the control module. For more information about the module configuration, see <a href="#">Chapter 18, Control Module</a> .
MPU INTC	MPU INTC configuration must be done to enable the interrupts from the general-purpose interface module. See <a href="#">Chapter 17, Interrupt Controllers</a> .
DSP INTC	DSP INTC configuration must be done to enable the interrupts from the general-purpose interface module. See <a href="#">Chapter 17, Interrupt Controllers</a> .

##### 25.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure initializes the general-purpose interface module after a POR or software reset.

**Table 25-12. General-Purpose Interface Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Execute software reset.	GPIO_SYSCONFIG[1] SOFTRESET	0x1
Wait until reset completed?	GPIO_SYSSTATUS[0] RESETDONE	= 0x1
Configure idle mode.	GPIO_SYSCONFIG[4:3] IDLEMODE	0x–
Configure interface clock gating.	GPIO_SYSCONFIG[0] AUTOIDLE	0x–
Set clock gating power saving.	GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and GPIO_RISINGDETECT[31:0] RISINGDETECT and GPIO_FALLINGDETECT[31:0] FALLINGDETECT	0x0000 00FF
Set clock gating ratio.	GPIO_CTRL[2:1] GATINGRATIO	0x–
Configure GPIO channels as input or output.	GPIO_OE[31:0] OUTPUTEN	0x–
Set debounce time value.	GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME	0x–
Enable/disable debouncing for desired input line.	GPIO_DEBOUNCENABLE[7:0] DEBOUNCENABLE	0x–
<b>Interrupt and Wake-Up Request Configuration</b>		
Enable/disable interrupts.	GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE	0x–
Enable/disable wakeup for GPIO channels.	GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE	0x–
Enable/disable wake-up generation.	GPIO_SYSCONFIG[2] ENAWAKEUP	0x1

## 25.5.1.2 General-Purpose Interface Operational Modes Configuration

### 25.5.1.2.1 General-Purpose Interface Read Input Register

**Table 25-13. General-Purpose Interface Read Input Register**

Step	Register/Bit Field/Programming Model	Value
Read input register value.	<a href="#">GPIO_DATAIN</a> [31:0] DATAIN	0x-

### 25.5.1.2.2 General-Purpose Interface Write Output Register

**Table 25-14. General-Purpose Interface Write Output Register**

Step	Register/Bit Field/Programming Model	Value
Write value to output register.	<a href="#">GPIO_DATAOUT</a> [31:0] DATAOUT	0x-

### 25.5.1.2.3 General-Purpose Interface Set Bit Function

**Table 25-15. General-Purpose Interface Set Bit Function**

Step	Register/Bit Field/Programming Model	Value
Write 0x1 to set desired bit(s) in register.	<a href="#">GPIO_SETDATAOUT</a> [31:0] INTLINE	0x-
	<a href="#">GPIO_IRQSTATUS_SET_0</a> [31:0] INTLINE	
	<a href="#">GPIO_IRQSTATUS_SET_1</a> [31:0] INTLINE	

### 25.5.1.2.4 General-Purpose Interface Clear Bit Function

**Table 25-16. General-Purpose Interface Clear Bit Function**

Step	Register/Bit Field /Programming Model	Value
Write 0x1 to clear desired bit(s) in register.	<a href="#">GPIO_CLEARDATAOUT</a> [31:0] INTLINE	0x1
	<a href="#">GPIO_IRQSTATUS_CLR_0</a> [31:0] INTLINE	
	<a href="#">GPIO_IRQSTATUS_CLR_1</a> [31:0] INTLINE	

## 25.6 General-Purpose Interface Register Manual

### 25.6.1 General-Purpose Interface Instance Summary

Table 25-17 summarizes the general-purpose interface instance.

**Table 25-17. Instance Summary**

Module Name	Base Address	Size
GPIO1	0x4A31 0000	4KB
GPIO2	0x4805 5000	4KB
GPIO3	0x4805 7000	4KB
GPIO4	0x4805 9000	4KB
GPIO5	0x4805 B000	4KB
GPIO6	0x4805 D000	4KB

### 25.6.2 General-Purpose Interface Registers

#### 25.6.2.1 General-Purpose Interface Register Summary

Table 25-18 summarizes the general-purpose interface GPIO1 to GPIO3 registers.

**Table 25-18. General-Purpose Interface GPIO1 to GPIO3 Registers Summary**

Register Name	Type	Register Width (Bits)	Address Offset	GPIO1 L4 Physical Address	GPIO2 L4 Physical Address	GPIO3 L4 Physical Address

<b>Address Offset</b>	0x0000 0010	<b>Instance</b>	GPIO1
<b>Physical Address</b>	<a href="#">0x4A31 0010</a> <a href="#">0x4805 5010</a> <a href="#">0x4805 7010</a> <a href="#">0x4805 9010</a> <a href="#">0x4805 B010</a> <a href="#">0x4805 D010</a>		GPIO2 GPIO3 GPIO4 GPIO5 GPIO6
<b>Description</b>	System configuration register		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												IDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Reserved	R	0x0000000
4:3	IDLEMODE	0x0: Force-idle: An idle request is acknowledged unconditionally. 0x1: No-idle: An idle request is never acknowledged. 0x2: Smart-idle: The acknowledgment to an idle request is given based on the internal activity (see 4.1.2). 0x3: Smart-idle wakeup	RW	0x0
2	ENAWAKEUP	Wake-up control 0x0: Wake-up generation is disabled. 0x1: Wake-up capability is enabled upon expected transition on input GPIO pin.	RW	0
1	SOFTRESET	Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0
0	AUTOIDLE	OCP clock gating control. 0x0: Internal Interface OCP clock is free-running. 0x1: Automatic internal OCP clock gating, based on the OCP interface activity	RW	0

## 26.1 Keyboard Controller Overview

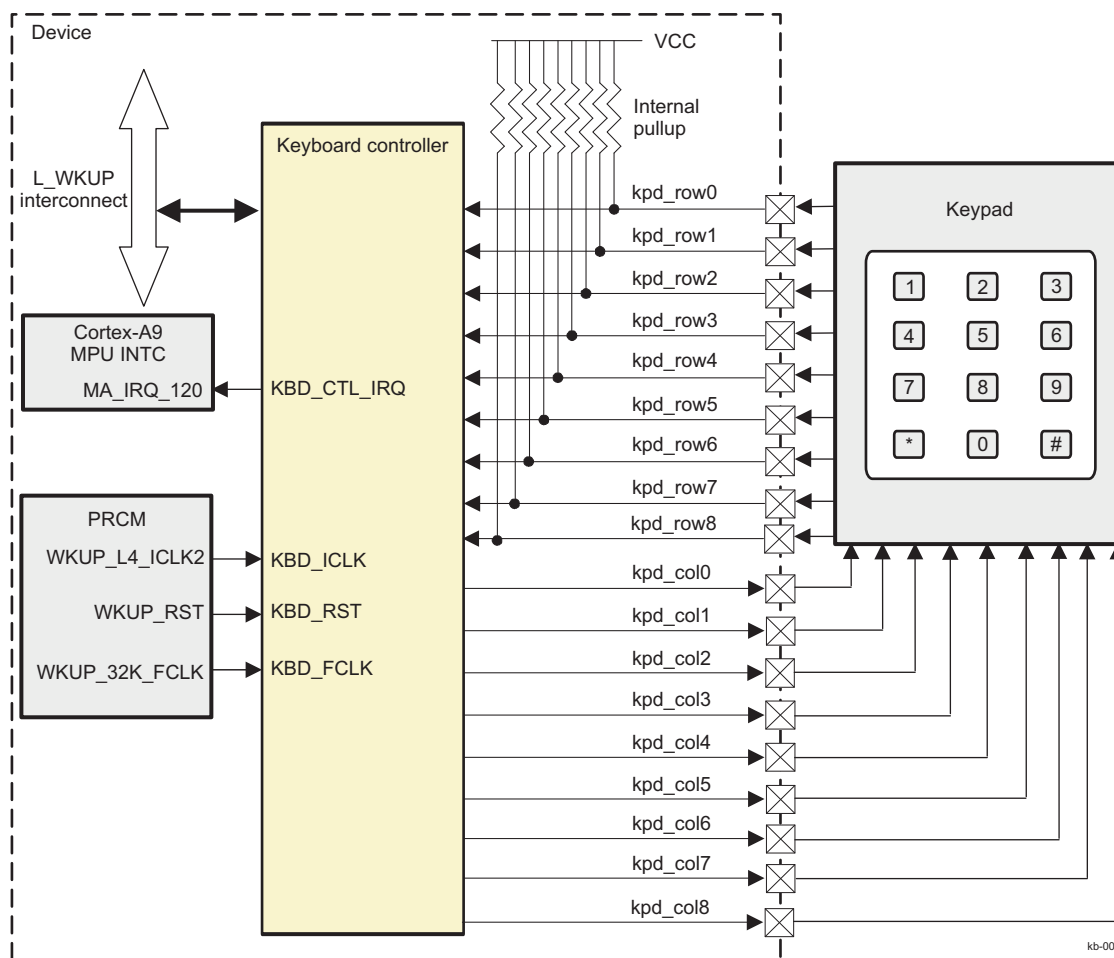

The keyboard controller implements a built-in scanning algorithm for hardware-based key-press decoding and reduces overhead in the microprocessor unit (MPU) software.

The keyboard controller includes a debouncing feature to ensure that only one key combination can be registered in the programmed time.

The keyboard controller can handle up to 9 × 9 keys, works on a 32-kHz clock, and can generate wake-up events when the chip is in sleep mode.

Figure 26-1 shows the keyboard controller.

**Figure 26-1. Keyboard Controller Overview**

The keyboard controller includes the following main features:

- Support of multiconfiguration keyboards up to 9 rows × 9 columns
- Each key coded on 1 bit in two 32-bit registers
- Long-key value or repeat timing reconfigurable on the fly
- Event detection on key press and key release
- Multikey-press detection and decoding
- Long-key detection on prolonged key press
- Integrated timer with four programmable comparison values
- Programmable time-out on permanent key press or after keyboard release
- Programmable interrupt generation on key events
- Software reset capability

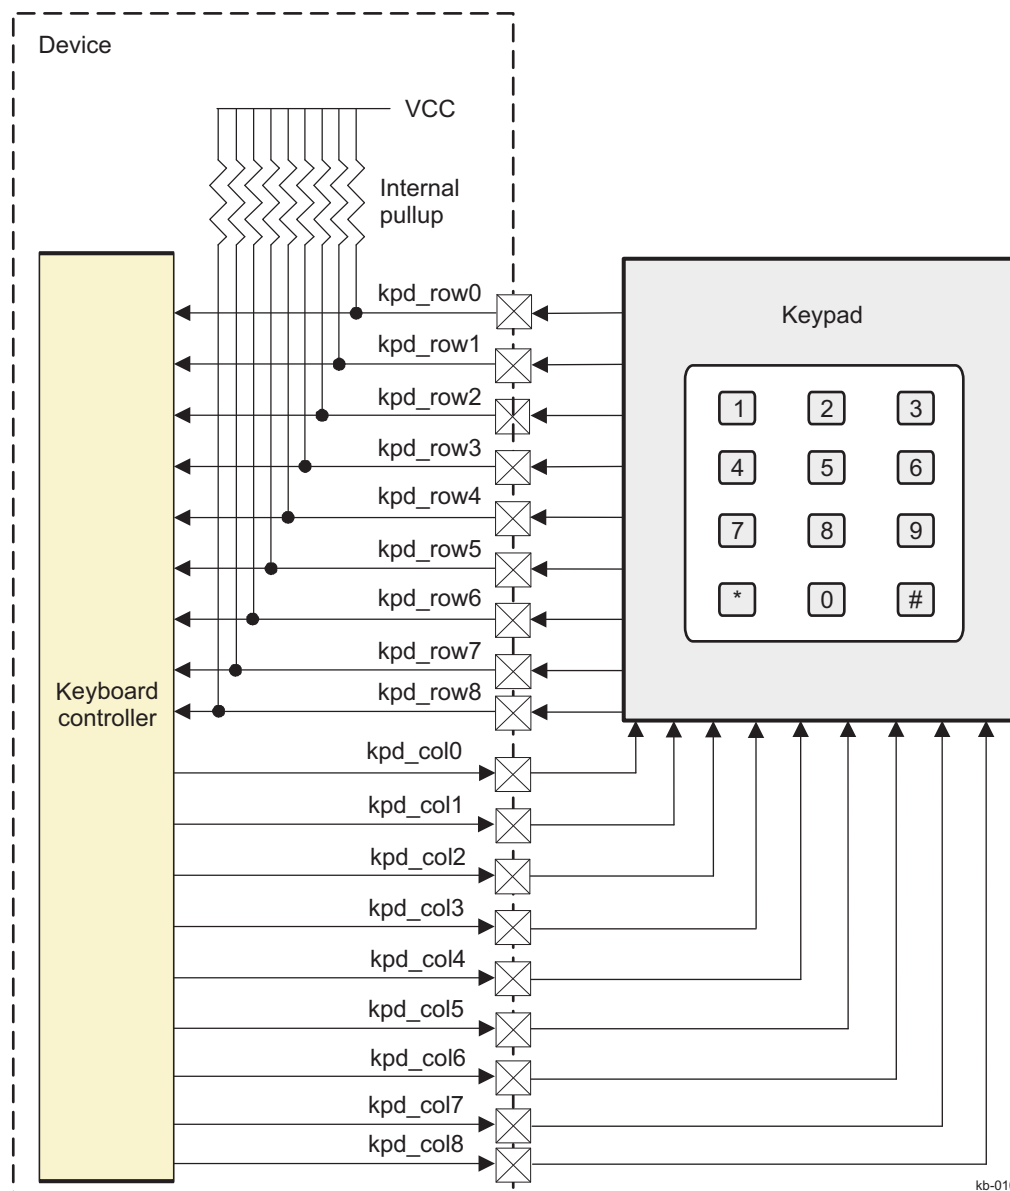

- Read/write-posted register access modes
- 8-/16-/32-bit access supported on the level 4 (L4) interface
- 32-bit data bus
- 7-bit address bus

## 26.2 Keyboard Controller Environment

The keyboard controller external interface pins map on the device pads when the device general-purpose input/output (GPIO) cells are configured and multiplexed for the keypad function by the control module. For more information, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), and [Section 25.2.1, General-Purpose Interface as a Keyboard interface](#).

The external keypad typically connects directly to the keyboard controller of the device (see [Figure 26-2](#)).

**Figure 26-2. Typical Keyboard Environment**

### 26.2.1 Keyboard Controller Functions/Modes

The keyboard controller executes two functions:

- Keypad scanning and decoding for input of the external key presses. For more information, see [Section 26.4.5, Keyboard Controller Software Mode](#), and [Section 26.4.6, Keyboard Controller Hardware Decoding Modes](#).
- Device wake-up by interrupt request to the processor when a key is pressed and the device is in idle or sleep mode. For more information, see [Section 26.4.6.4, Keyboard Controller Interrupt Generation](#).

### 26.2.2 Keyboard Controller Signals

Table 26-1 describes the module signals and specifies their links to functions.

**Table 26-1. I/O External Keyboard Signals**

Signal	I/O <sup>(1)</sup>	Description	Reset Value <sup>(2)</sup>	Function	Wake-Up Capability
kpd_row0	I	Keypad row 0 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row1	I	Keypad row 1 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row2	I	Keypad row 2 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row3	I	Keypad row 3 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row4	I	Keypad row 4 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row5	I	Keypad row 5 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row6	I	Keypad row 6 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row7	I	Keypad row 7 feed	hi-Z (pulled up)	Key reading	Yes
kpd_row8	I	Keypad row 8 feed	hi-Z (pulled up)	Key reading	Yes
kpd_col0	O	Keypad column 0 feed, active low	hi-Z	Key reading	No
kpd_col1	O	Keypad column 1 feed, active low	hi-Z	Key reading	No
kpd_col2	O	Keypad column 2 feed, active low	hi-Z	Key reading	No
kpd_col3	O	Keypad column 3 feed, active low	hi-Z	Key reading	No
kpd_col4	O	Keypad column 4 feed, active low	hi-Z	Key reading	No
kpd_col5	O	Keypad column 5 feed, active low	hi-Z	Key reading	No
kpd_col6	O	Keypad column 6 feed, active low	hi-Z	Key reading	No
kpd_col7	O	Keypad column 7 feed, active low	hi-Z	Key reading	No
kpd_col8	O	Keypad column 8 feed, active low	hi-Z	Key reading	No

<sup>(1)</sup> I = Input; O = Output; I/O = Bidirectional

<sup>(2)</sup> hi-Z = High impedance

### 26.2.3 Protocols and Data Formats

The keyboard controller detects and decodes multikey combinations using the following rules:

- Any 2-key combination is valid and can be decoded.
- Combinations using more than two keys are valid only if the rows and columns used do not cross over on another key to be detected. This is caused by equipotent propagation on a row/column (multikey limitations).

Figure 26-3 shows an example of multikey limitation.

**Figure 26-3. Multikey Limitation Example**

kb-007

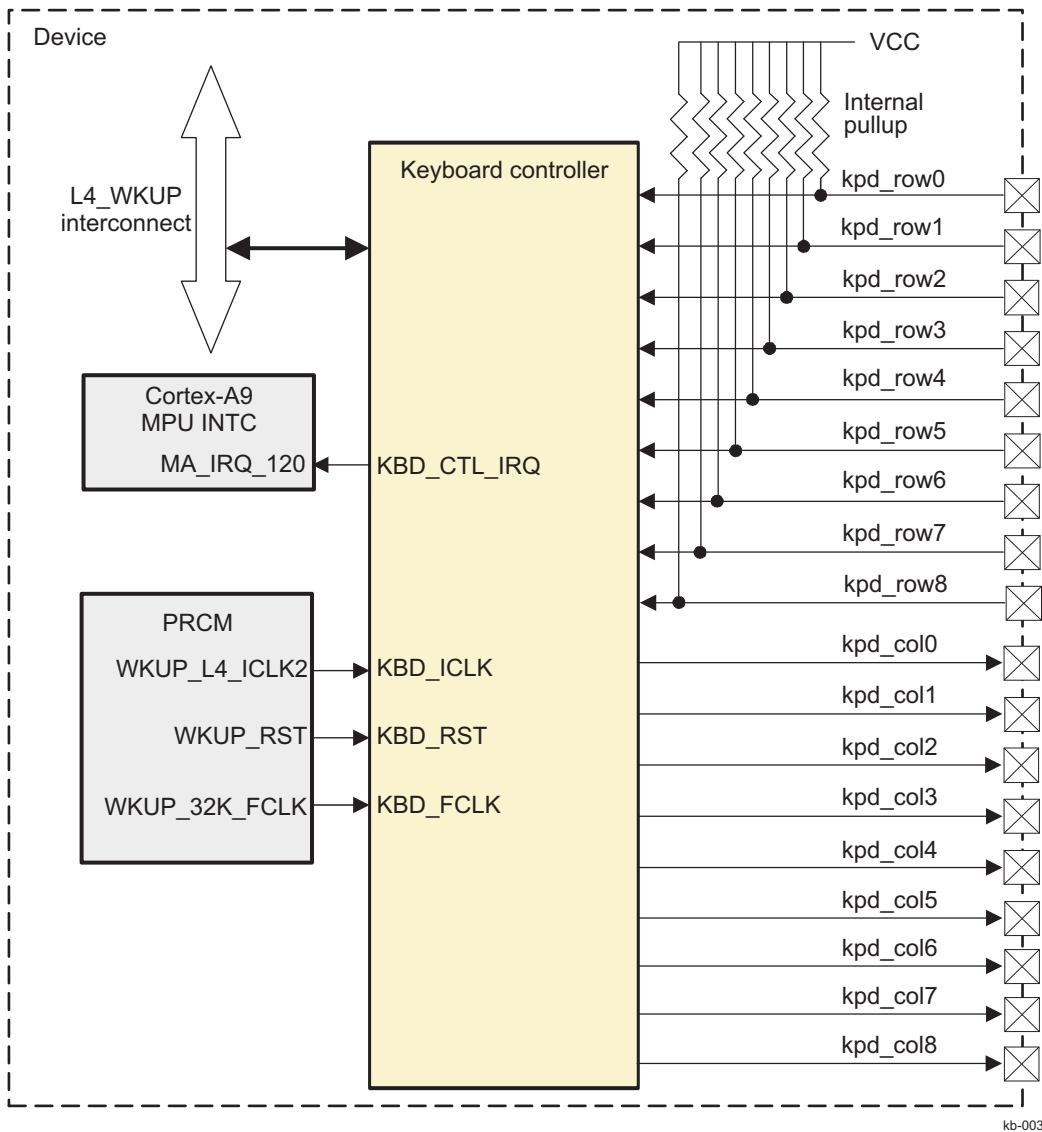

**NOTE:** When using the keyboard controller with a smaller keypad (for example, 5 × 5), unused rows must be tied high to prevent disturbing the scanning process. Normally, all rows must be pulled up internally at the I/O cells of the device.

---

### 26.3 Keyboard Controller Integration

Figure 26-4 shows keyboard controller integration.

Figure 26-4. Keyboard Controller Integration

The control module must enable the internal pullups of the GPIO cells for all keypad rows (for more information about configuration, see [Chapter 18, Control Module](#)).

[Table 26-2](#) through [Table 26-4](#) summarize the integration of the module in the device.

Table 26-2. Integration Attributes

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
KEYBOARD CONTROLLER	PD_WKUP	Yes	L4_WKUP

Table 26-3. Clocks and Resets

KEYBOARD CONTROLLER	KBD_CTL_IRQ	MA_IRQ_120	Cortex™-A9 INTC	Interrupt signal to the interrupt controller (INTC) of the MPU. For information about INTC interrupt control, see <a href="#">Chapter 17, Interrupt Controllers</a> .

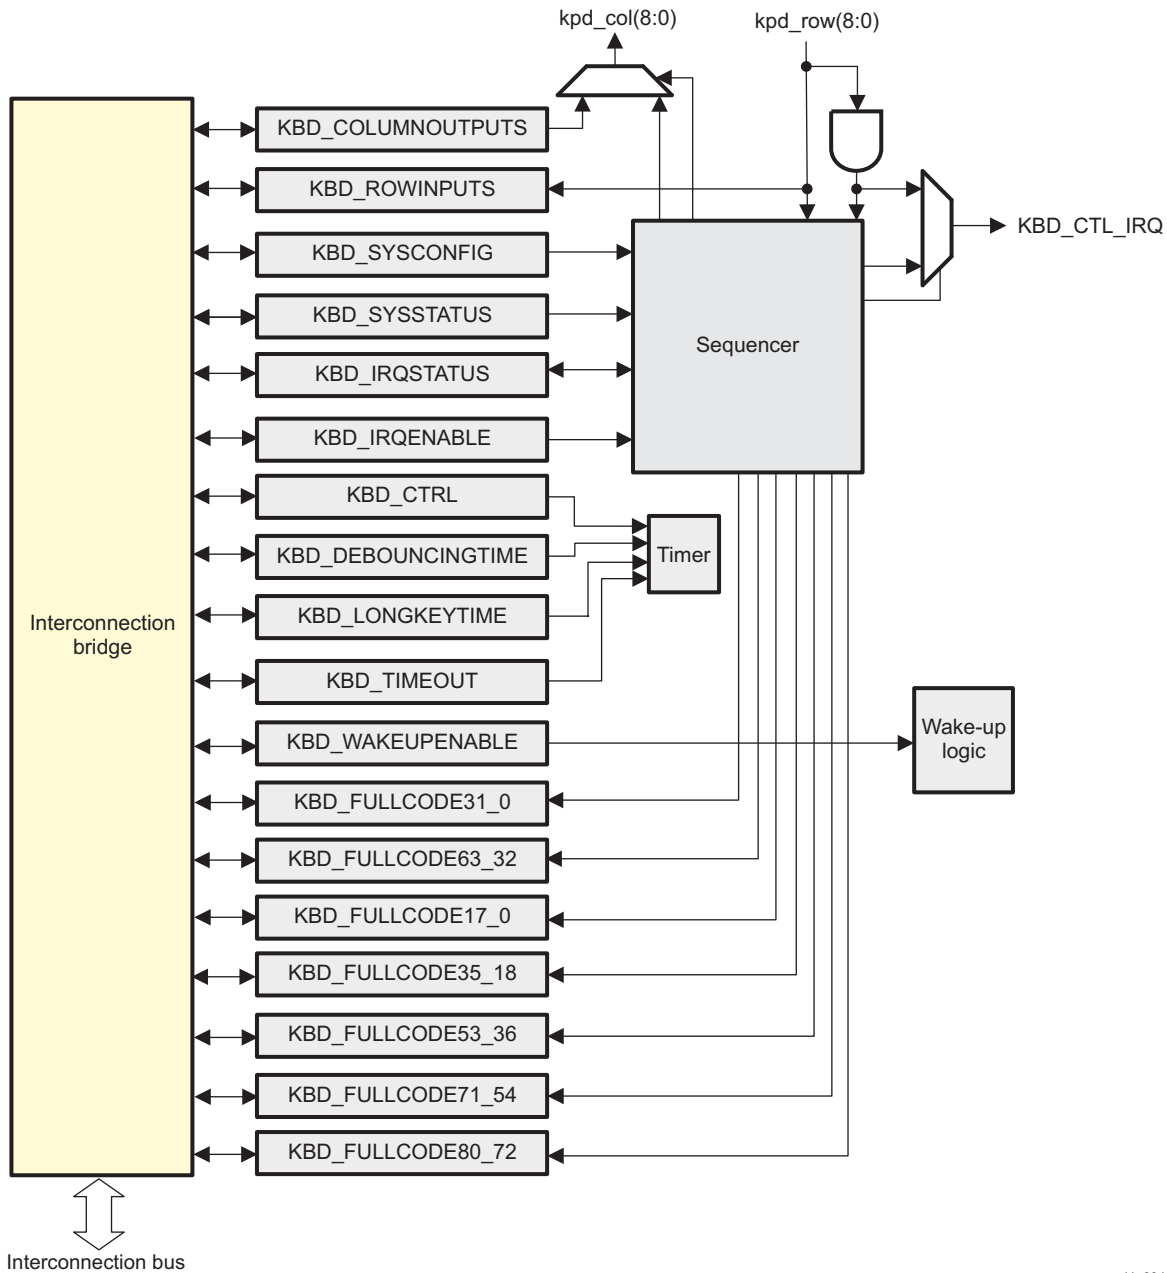

**NOTE:** For the description of the interrupt source, see [Section 26.4.4, Interrupt Requests](#).

## 26.4 Keyboard Controller Functional Description

### 26.4.1 Keyboard Controller Block Diagram

Figure 26-5 shows the functional specification block diagram of the keyboard controller.

Figure 26-5. Keyboard Controller Block Diagram

kb-004

The keyboard controller detects events issued on any key of the connected keyboard and generates an interrupt to alert the host processor. The built-in hardware-scan algorithm decodes the pressed keys, including multikey combinations.

To reduce MPU software overhead, the hardware performs detecting and decoding in the keyboard controller state-machine. However, hardware decoding can be deactivated so that software handles the scanning algorithm.

The value of the columns output is determined in the [KBD\\_COLUMNOUTPUTS\[8:0\]](#) KBC\_REG bit field. To activate a keypad row-column connection, the corresponding bit must be 0b0.

The following sections describe subfunctions and subfunction interactions (control, data paths).

### 26.4.2 Keyboard Controller Software Reset

To perform a software reset, set the [KBD\\_SYSCONFIG\[1\]](#) SOFTRESET bit to 1. The [KBD\\_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [KBD\\_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing mailbox operations.

### 26.4.3 Keyboard Controller Power Management

[Table 26-5](#) describes the power-management features available for the keyboard controller.

**NOTE:** For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

**Table 26-5. Local Power-Management Features**

Feature	Registers	Description
Clock autogating	<a href="#">KBD_SYSCONFIG[0]</a> AUTOGATING	This bit allows local power optimization in the module by gating the KBD_ICLK clock upon interface activity, or gating KBD_FCLK upon internal activity.
Slave idle modes	<a href="#">KBD_SYSCONFIG[4:3]</a> IDLEMODE	Force-idle, no-idle, and smart-idle modes are available.
Clock activity	<a href="#">KBD_SYSCONFIG[9:8]</a> CLOCKACTIVITY	For configuration details, see <a href="#">Table 26-6</a> .
Master standby modes	N/A	N/A
Global wake-up enable	<a href="#">KBD_SYSCONFIG[2]</a> ENAWAKEUP	This bit enables the wake-up feature at the module level. If smart-idle mode is selected, this bit provides the option of smart-idle wake-up-capable mode.
Wake-up sources enable	<a href="#">KBD_WAKEUPENABLE</a>	This register holds one active-high enable bit per event source able to generate a wake-up signal.

[Table 26-6](#) lists the clock activity settings.

**Table 26-6. Clock Activity Settings**

<a href="#">KBD_SYSCONFIG</a> [9:8] CLOCKACTIVITY Values	Clock State When Module is in IDLE State		Features Available When Module is in IDLE State	Wake-Up Events
	<a href="#">KBD_ICLK</a>	<a href="#">KBD_FCLK</a>		
00	OFF	OFF	None	The wake-up capability of the module is disabled.
10	OFF	ON	All	Asserting of wake-up signal
01	ON	OFF	None	The wake-up capability of the module is disabled.
11	ON	ON	All	Asserting of wake-up signal

**CAUTION**

The PRCM module has no hardware means of reading the CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the keyboard controller CLOCKACTIVITY and keyboard controller clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

### 26.4.4 Keyboard Controller Interrupt Requests

[Table 26-7](#) lists the event flags, and their mask, that can cause module interrupts.

**Table 26-7. Events**

Event Flag	Event Mask	Description
<a href="#">KBD_IRQSTATUS</a> [3] MISS_EVENT	–	A miss event occurs.
<a href="#">KBD_IRQSTATUS</a> [2] IT_TIMEOUT	<a href="#">KBD_IRQENABLE</a> [2] IT_TIMEOUT_EN	A time-out event is detected.
<a href="#">KBD_IRQSTATUS</a> [1] IT_LONG_KEY	<a href="#">KBD_IRQENABLE</a> [1] IT_LONG_KEY_EN	A long-key event is detected.
<a href="#">KBD_IRQSTATUS</a> [0] IT_EVENT	<a href="#">KBD_IRQENABLE</a> [0] IT_EVENT_EN	An event is detected.

### 26.4.5 Keyboard Controller Software Mode

The [KBD\\_CTRL](#)[1] NSOFTWARE\_MODE bit selects software mode when it is set to 0.

In software mode, the keyboard controller internal sequencer, which performs automatic scanning and decoding, is disabled. Consequently, software must manually perform the scanning algorithm.

The scanning sequence is managed using the keyboard controller column outputs register ([KBD\\_COLUMNOUTPUTS](#)) and the keyboard controller row inputs register ([KBD\\_ROWINPUTS](#)). In this configuration, the keyboard interrupt is a logical ANDing of all bits of the [KBD\\_ROWINPUTS](#) register.

For more information about the software scan, see [Section 26.5.1, Keyboard Controller Low-Level Programming Model](#).

### 26.4.6 Keyboard Controller Hardware Decoding Modes

#### 26.4.6.1 Functional Modes

When running in hardware (default) decoding mode (the [KBD\\_CTRL](#)[1] NSOFTWARE\_MODE bit is set to 1), the keyboard controller offers several functional modes; these modes are summarized in [Table 26-8](#). The keyboard interrupt depends on the configuration in the keyboard controller interrupt-enable register ([KBD\\_IRQENABLE](#)). If the event is enabled (bit 0 at 1), an interrupt is generated when the sequencer detects an event. Even if this interrupt is disabled, the flag status of the keyboard controller interrupt-status register ([KBD\\_IRQSTATUS](#)) is updated.

**Table 26-8. Keyboard Controller Functional Modes**

Functional Mode	Associated Interrupt	Associated Timer Value	Description	Control
Keyboard event	Event interrupt	Debouncing value	Occurs when a key is pressed or released Always enabled	<a href="#">KBD_CTRL</a> [8:5] bits must be set to 0 to disable all the other features.
Long key	Long-key interrupt	Long-key value	Used to detect a key that is pressed for a long time Should be associated with the long-key time-out function or repeat mode	<a href="#">KBD_CTRL</a> [5] LONG_KEY bit

**Table 26-8. Keyboard Controller Functional Modes (continued)**

Functional Mode	Associated Interrupt	Associated Timer Value	Description	Control
Repeat key	Long-key interrupt	Long-key value	Generates an interrupt every long-key delay No time-out can be associated.	<a href="#">KBD_CTRL</a> [8] REPEAT_MODE bit
Empty time-out	Time-out interrupt	Empty time-out value	Interrupt generated if no key is pressed during an empty time-out period.	<a href="#">KBD_CTRL</a> [6] TIMEOUT_EMPTY bit
Long-key time-out	Time-out interrupt	Long-key time-out value	Associated with the long-key function Generated after a long-key interrupt if no event occurs during a long-key time-out period	<a href="#">KBD_CTRL</a> [7] TIMEOUT_LONG_KEY bit

Each mode can be activated/deactivated by setting the corresponding bits (5, 6, 7, and 8) in the [KBD\\_CTRL](#) register with the appropriate values (for more information, see [Section 26.6, Keyboard Controller Register Manual](#)).

#### 26.4.6.2 Keyboard Controller Timer

As described in the previous section, each functional mode is associated with a timer value. Depending on the selected mode, the keyboard controller timer is loaded with the corresponding value as set in the related registers:

- [KBD\\_DEBOUNCINGTIME](#)
- [KBD\\_KEYLONGTIME](#)
- [KBD\\_TIMEOUT](#)

[Table 26-9](#) summarizes the values of the keyboard controller timer.

**Table 26-9. Keyboard Controller Timer Values**

Timer Value	Associated Register Field	Description
Debouncing time	<a href="#">KBD_DEBOUNCINGTIME</a> [5:0] DEBOUNCING_VALUE	To remove the effects of glitches when an event occurs on the keyboard, the controller waits for a debouncing period before taking a snapshot of the current state on the keyboard matrix. The timer is loaded with the debouncing time value after each detected event on the keyboard matrix. An event interrupt is generated after this delay.
Long-key time	<a href="#">KBD_KEYLONGTIME</a> [11:0] LONG_KEY_VALUE	This is the delay before generating a long-key interrupt after an event interrupt. If the long-key mode is selected, the timer is loaded with the long-key time value after an event interrupt is generated.  In repeat mode, the timer is reloaded with the same value after a long-key interrupt, and starts to count down again.
Long-key time-out	<a href="#">KBD_TIMEOUT</a> [15:0] TIMEOUT_VALUE	The timer is loaded with the time-out value and then a long-key interrupt is generated and starts to count down. When it reaches 0, a time-out interrupt is generated and the keyboard controller returns to its IDLE state. This long-key time-out does not work in repeat mode.
Empty key time-out	<a href="#">KBD_TIMEOUT</a> [15:0] TIMEOUT_VALUE	The time-out interrupt occurs if no key is pressed during this delay. The keyboard controller then returns to IDLE state.

The timer countdown period depends on three factors:

- The loaded value as set in:
  - [KBD\\_DEBOUNCINGTIME](#)
  - [KBD\\_KEYLONGTIME](#)
  - [KBD\\_TIMEOUT](#)
- The value of the prescale clock timer as set in the [KBD\\_CTRL](#)[4:2] PTV bit field. This programmable clock divider allows the reduction of the clock frequency used by the timer.
- The frequency of the keyboard controller functional clock (32 kHz)

The period is calculated as follows:

$$T_{\text{period}} = (T_{\text{value}} + 1) \times 2^{\text{PTV} + 1} \times T_{\text{clk}}$$

Where:

$T_{\text{value}}$  is the value stored in the [KBD\\_DEBOUNCINGTIME](#), [KBD\\_KEYLONGTIME](#), or [KBD\\_TIMEOUT](#) register.

PTV is the value of the [KBD\\_CTRL\[4:2\]](#) register PTV bit field.

$T_{\text{clk}}$  is the period of the 32-kHz functional clock; that is, 31.25  $\mu\text{s}$ .

The [KBD\\_CTRL\[4:2\]](#) PTV bit field determines the division factor of the timer clock. [Table 26-10](#) lists the divider rates.

**Table 26-10. Timer Prescale Values**

<a href="#">KBD_CTRL[4:2]</a> PTV Value	Divisor
0	2
1	4
2	8
3	16
4	32
5	64
6	128
7	256

**NOTE:** The timer minimum period is 62.5  $\mu\text{s}$ ; its maximum period is 524.288 seconds.

**CAUTION**

To prevent undefined results, the [KBD\\_CTRL\[4:2\]](#) PTV bit field must not be changed when the timer is running.

The timer value registers ([KBD\\_DEBOUNCINGTIME](#), [KBD\\_KEYLONGTIME](#), and [KBD\\_TIMEOUT](#)) can be updated at any time, whether or not the timer is running. Nevertheless, the timer is updated only on the fly for the long-key time value. The new debouncing and time-out values are loaded only on the next load. Depending on the updated register, two cases can occur:

- The [KBD\\_KEYLONGTIME](#) register is updated; the new value stored in the [KBD\\_KEYLONGTIME](#) register is loaded into the timer when the register is written. If the timer is already counting down when [KBD\\_KEYLONGTIME](#) is updated, it counts down from the new value loaded in [KBD\\_KEYLONGTIME](#).
- The [KBD\\_DEBOUNCINGTIME](#) or [KBD\\_TIMEOUT](#) register is updated; the new value is considered only when the next timer loads. If the timer is counting down when the registers are updated, the timer continues counting down from the previous value and is loaded with the new one on the next load.

Regardless of the timer state (stopped, counting down any of the values previously described, etc.), when a new event occurs on the keyboard, the timer is stopped and loaded with the debouncing time value. It then starts counting down.

### 26.4.6.3 State-Machine Status

To facilitate debugging, each state of the state-machine is coded in a register that indicates the current state of the machine. [Table 26-11](#) lists the corresponding codes.

**Table 26-11. State-Machine Values**

<b>KBD_STATEMACHINE[3:0] Value</b>	<b>Description</b>
0x0	Idle
0x1	Scanning
0x2	Load timer debouncing
0x3	Test timer debouncing
0x4	Generated interrupt event
0x6	Load timer long key
0x7	Test timer long key
0x8	Generated interrupt long key
0x9	Load timer time-out
0xA	Test timer time-out
0xB	Generated interrupt time-out
0xF	Other

#### 26.4.6.4 Keyboard Controller Interrupt Generation

##### 26.4.6.4.1 Interrupt-Generation Scheme

The keyboard controller generates one interrupt signal to external INTC KBD\_CTL\_IRQ. Each functional mode generates dedicated interrupt events (logged in the [KBD\\_IRQSTATUS](#) register) that can be masked or unmasked using the [KBD\\_IRQENABLE](#) register.

The [KBD\\_IRQSTATUS](#) register is updated when the selected functional mode generates an interrupt event. However, the KBD\_CTL\_IRQ signal is asserted on the related event only when the corresponding bit is set in the [KBD\\_IRQENABLE](#) register.

---

**NOTE:** To reset the interrupt status bit, 1 must be written to the appropriate bit of the [KBD\\_IRQSTATUS](#) read/write register.

---

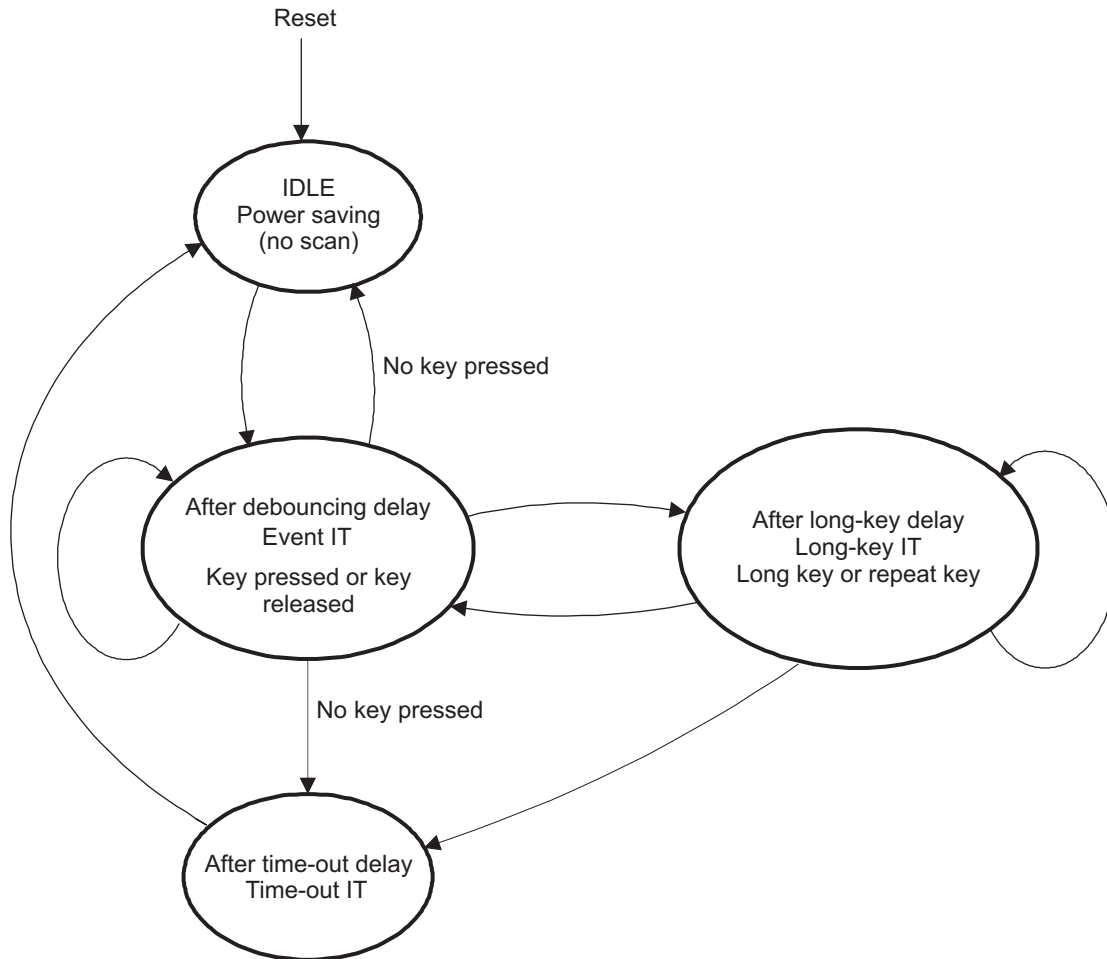

[Figure 26-6](#) shows the different interrupt events generated in each keyboard controller functional mode and details the relationships between them.

---

**NOTE:** Depending on the selected mode, some interrupt events cannot be generated.

---

Figure 26-6. Functional Modes and Related Interrupt Events

kb-005

While running in hardware-decoding mode, the keyboard controller performs automatic scans when not in IDLE state. When a key-press event occurs on the keyboard matrix, the keyboard controller leaves IDLE state and an interrupt event (the `KBD_IRQSTATUS[0]` IT\_EVENT bit) is set after the timer counts down the debouncing delay. An IT\_EVENT is generated when a key is pressed or released.

---

**NOTE:** An IT\_EVENT is generated regardless of the selected functional mode. If no time-out is set and no more keys are pressed, the keyboard controller returns to IDLE state.

---

If long-key detection mode is set when the timer counts down the long-key delay, an interrupt long key (the `KBD_IRQSTATUS[1]` IT\_LONG\_KEY bit) is generated. If the repeat mode is set, the IT\_LONG\_KEY interrupt is generated periodically every long-key delay.

A time-out can also be set in event detection or long-key detection mode. In this case, a time-out interrupt (the `KBD_IRQSTATUS[2]` IT\_TIMEOUT bit) is generated after the time-out delay timer expires. After such an interrupt, the keyboard controller always returns to IDLE state.

---

**NOTE:** No time-out can be set in repeat mode. Only a keyboard event can stop the periodic interrupt generation.

---

### 26.4.6.4.2 Keyboard Buffer and Missed Events (Overrun Feature)

The keyboard controller has an overrun feature: A dedicated buffer allows the keyboard controller to memorize two successive events. If two successive events occur before a read is performed, the second event is stored and a second interrupt is generated when the first interrupt is cleared, allowing two consecutive key events to be received.

If a third event occurs before the first event is treated, a missed event interrupt (the `KBD_IRQSTATUS[3] MISS_EVENT` bit) is generated to report the lost event.

---

**NOTE:** The `MISS_EVENT` interrupt is not routed to the `KBD_CTL_IRQ` signal; software must check the `KBD_IRQSTATUS[3] MISS_EVENT` bit to detect any missed events.

---

### 26.4.7 Keyboard Controller Key Coding Registers

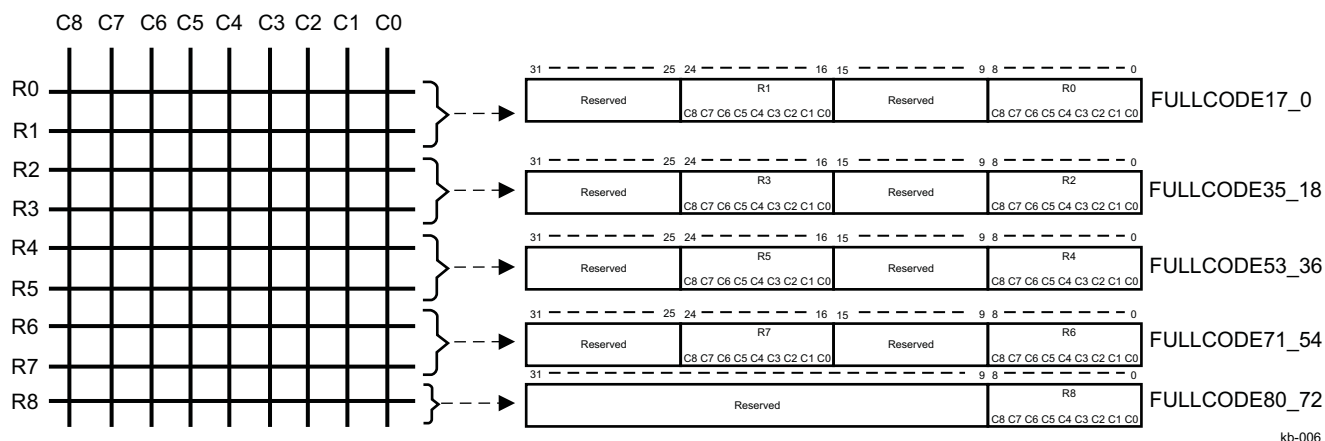

The keyboard controller matrix pressed keys state (indicating which columns/rows are connected) is reflected in the `KBD_FULLLCODE17_0` to `KBD_FULLLCODE80_72` registers, as shown in Figure 26-7. These registers are updated only when interrupt event status is inactive to prevent a lost event.

---

**NOTE:** The `KBD_FULLLCODE31_0` and `KBD_FULLLCODE63_32` registers, which are limited to supporting keyboards of a maximum 8 × 8 array size, can be used for back-to-back software compatibility.

---

**Figure 26-7. Key Coding Registers**

kb-006

Each of the 9 × 9 keyboard size supporting registers (`KBD_FULLLCODE17_0` up to `KBD_FULLLCODE71_54`) stores the state of two keyboard rows. The `KBD_FULLLCODE80_72` register stores the state of the last row, R8:

- The `KBD_FULLLCODE17_0` register code rows 0, 1 (row 0 is coded between bits 0 and 8, row 1 is coded between bits 16 and 24)
- The `KBD_FULLLCODE35_18` register code rows 2, 3 (row 2 is coded between bits 0 and 8, row 3 is coded between bits 16 and 24)
- The `KBD_FULLLCODE53_36` register code rows 4, 5 (row 4 is coded between bits 0 and 8, row 5 is coded between bits 16 and 24)
- The `KBD_FULLLCODE71_54` register code rows 6, 7 (row 6 is coded between bits 0 and 8, row 7 is coded between bits 16 and 24)
- The `KBD_FULLLCODE80_72` register code row 8 (row 8 is coded between bits 0 and 8)

In each of these registers (excluding `KBD_FULLLCODE80_72`):

- Bit 0 corresponds to column(0) – row (i) key, ... , bit 8 corresponds to column(8) – row (i) key.
- Bits from 9 to 15 are reserved.

- Bit 16 corresponds to column(0) – row (i+1) key, ... , bit 24 corresponds to column (8) – row (i+1) key.
- Bits 31 to 25 are reserved, where i = 0, 2, 4, 6.

In register [KBD\\_FULLCODE80\\_72](#) bit 0 corresponds to column (0) – row (8) key, ..., the bit 8 corresponds to column (8) – row (8) key, and the remaining bits (from 9 to 31) are reserved.

Each of the 8 × 8-keyboard size supporting registers ([KBD\\_FULLCODE31\\_0](#) and [KBD\\_FULLCODE63\\_32](#)) stores the state of four keyboard rows:

- The [KBD\\_FULLCODE31\\_0](#) register code rows 0, 1, 2, and 3 (row 0 is coded between bits 0 and 7, row 1 is coded between bits 8 and 15, row 2 is coded between bits 16 and 23, and row 3 is coded between bits 24 and 31)
- The [KBD\\_FULLCODE63\\_32](#) register code rows 4, 5, 6, and 7 (row 4 is coded between bits 0 and 7, row 5 is coded between bits 8 and 15, row 6 is coded between bits 16 and 23, and row 7 is coded between bits 24 and 31)

In these registers:

- [KBD\\_FULLCODE31\\_0](#)[0] corresponds to column (0) – row (0) key, ..., [KBD\\_FULLCODE31\\_0](#)[7] corresponds to column (7) – row (0).
- [KBD\\_FULLCODE31\\_0](#)[8] corresponds to column (0) – row (1) key, ..., [KBD\\_FULLCODE31\\_0](#)[15] corresponds to column (7) – row (1).
- [KBD\\_FULLCODE31\\_0](#)[16] corresponds to column (0) – row (2) key, ..., [KBD\\_FULLCODE31\\_0](#)[23] corresponds to column (7) – row (2).
- [KBD\\_FULLCODE31\\_0](#)[24] corresponds to column (0) – row (3) key, ..., [KBD\\_FULLCODE31\\_0](#)[31] corresponds to column (7) – row (3).
- [KBD\\_FULLCODE63\\_32](#)[0] corresponds to column (0) – row (4) key, ..., [KBD\\_FULLCODE63\\_32](#)[7] corresponds to column (7) – row (4).
- [KBD\\_FULLCODE63\\_32](#)[8] corresponds to column (0) – row (5) key, ..., [KBD\\_FULLCODE63\\_32](#)[15] corresponds to column (7) – row (5).
- [KBD\\_FULLCODE63\\_32](#)[16] corresponds to column (0) – row (6) key, ..., [KBD\\_FULLCODE63\\_32](#)[23] corresponds to column (7) – row (6).
- [KBD\\_FULLCODE63\\_32](#)[24] corresponds to column (0) – row (7) key, ..., [KBD\\_FULLCODE63\\_32](#)[31] corresponds to column (7) – row (7).

---

**NOTE:** The keyboard fullcode registers are not updated in software mode.

---

---

**NOTE:** When using a smaller keyboard (for example, 5 × 5 or 4 × 4), the bits of the unused columns/rows are not used either.

---

## 26.4.8 Keyboard Controller Register Access

### 26.4.8.1 Write Registers Access

The keyboard module uses a posted-write scheme to update any internal registers. This means the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the functional clock domain. This has the advantage of not stalling the interconnect system or the CPU that requested the write transaction. For each functional register, a pending bit is provided that is set if there is a pending write access to this register. The pending bits are accessible in the keyboard pending write register ([KBD\\_PENDING](#)).

In this mode, it is mandatory that the CPU checks the pending bits before any write access in the functional registers. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can also lead to unexpected results).

A register read following a posted write (on the same register) may not read the previous write value if the write posted process is not complete. Software synchronization must be used to avoid noncoherent read.

This posted period is defined as the interval between the posted write access request and the reset of the pending bit in the `KBD_PENDING` register, and can be quantified:

$$T \text{ (reset posted bit maximum)} = 3 \times \text{Tick} + 3 \times \text{Tfuncclk}$$

The time it takes to accomplish the writing is:

$$T \text{ (write accomplish maximum)} = 1 \times \text{Tick} + 3 \times \text{Tfuncclk}$$

where:

Tick is the L4 interface clock period, and Tfuncclk is the functional clock period.

#### 26.4.8.2 Read Registers Access

The keyboard module uses a posted-read scheme for reading any internal register. The read transaction is immediately acknowledged on the L4 interface. The value of the functional register to be read must be previously synchronized. This has the advantage of not stalling the interconnect system or the CPU that requested the read transaction.

The posted-read scheme can be used only if  $\text{Freq}(\text{KBD\_FCLK}) < \text{Freq}(\text{KBD\_ICLK})/4$ .

## 26.5 Keyboard Controller Programming Guide

### 26.5.1 Keyboard Controller Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

#### 26.5.1.1 Global Initialization

##### 26.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the keyboard module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the keyboard. For more information, see [Section 26.2, Keyboard Controller Environment](#), and [Section 26.3, Keyboard Controller Integration](#).

[Table 26-12](#) describes the global initialization of surrounding modules.

**Table 26-12. Global Initialization of Surrounding Modules**

Surrounding Modules	Comments
PRCM	The module interface (WKUP_L4_ICLK2) and functional (WKUP_32K_FCLK) clocks must be enabled. See <a href="#">Section 3.10.2.1.2, Clock Management Global Initialization</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Cortex-A9 MPU INTC	Interrupt request KBD_CTL_IRQ from the keyboard must be unmasked. For more information, see <a href="#">Chapter 17, Interrupt Controllers</a> .
Control module	The PAD CONFIG registers must be configured in to map the keyboard interface signals on the device pins through the multiplexers (mux mode 0 must be switched on) to determine the signal directions and to enable the internal pullups of the GPIO cells for all the keyboard rows. For more information about configuration, see <a href="#">Section 18.4.8, Pad Functional Multiplexing and Configuration</a> , and <a href="#">Section 25.2.1, General-Purpose Interface as a Keyboard interface</a> .

##### 26.5.1.1.2 Keyboard Controller Global Initialization

###### 26.5.1.1.2.1 Main Sequence – Keyboard Controller Global Initialization

This procedure initializes the keyboard controller after a POR or software reset (see [Table 26-13](#)).

**Table 26-13. Keyboard Controller Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Configure the parameters of the L4 interface and enable the clock activity.	<a href="#">KBD_SYSCONFIG</a>	0x00000–
Configure the debouncing time of filtering the glitches on pressing or releasing key.	<a href="#">KBD_DEBOUNCINGTIME</a> [5:0] DEBOUNCING_VALUE	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	<a href="#">KBD_KEYLONGTIME</a> [11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	<a href="#">KBD_TIMEOUT</a> [15:0] TIMEOUT_VALUE	0x–
Define the logical value of the column outputs (KEYPAD configuration) (logical 0 bit = active column-row).	<a href="#">KBD_COLUMNOUTPUTS</a> [8:0] KBC_REG	0x–
Perform the functional configuration of the keyboard module and the prescale clock timer value.	<a href="#">KBD_CTRL</a>	0x00000–
Clear the interrupt-status register.	<a href="#">KBD_IRQSTATUS</a>	0x0000000F
Enable (0b1)/disable (0b0) certain keyboard events for generating an interrupt request.	<a href="#">KBD_IRQENABLE</a> [2:0] IT_..._EN	0x–

**Table 26-13. Keyboard Controller Global Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	<a href="#">KBD_WAKEUPENABLE</a> [2:0] WUP_..._ENA	0x–

## 26.5.1.2 Operational Modes Configuration

### 26.5.1.2.1 Keyboard Controller in Hardware Decoding Mode (Default Mode)

#### 26.5.1.2.1.1 Main Sequence – Keyboard Controller Hardware Mode

After reset, all available functional modes are disabled, except detect-event mode, which is always active. [Table 26-14](#) describes the keyboard controller hardware mode.

**Table 26-14. Keyboard Controller Hardware Mode**

Step	Register/Bit Field/Programming Model	Value
Activate the internal keyboard controller sequencer by setting the bit.	<a href="#">KBD_CTRL</a> [1] NSOFTWARE_MODE	0b1
Select the functional mode by setting its corresponding bit to 1.	<a href="#">KBD_CTRL</a> [8:5]	0x–
Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value).	<a href="#">KBD_KEYLONGTIME</a> [11:0] LONG_KEY_VALUE	0x–
Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt).	<a href="#">KBD_TIMEOUT</a> [15:0] TIMEOUT_VALUE	0x–
Configure the debouncing time of filtering the glitches on pressing or releasing key.	<a href="#">KBD_DEBOUNCINGTIME</a> [5:0] DEBOUNCING_VALUE	0x–
Clear the interrupt-status register.	<a href="#">KBD_IRQSTATUS</a>	0x0000000F
Enable (by writing 1)/disable (by writing 0) certain keyboard event for generating an interrupt request	<a href="#">KBD_IRQENABLE</a> [2:0] IT_..._EN	0x–
Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request.	<a href="#">KBD_WAKEUPENABLE</a> [2:0] WUP_..._ENA	0x–
Wait for the <a href="#">KBD_CTL_IRQ</a> interrupt signal assertion.		
Read the interrupt-status register to determine which event caused the interrupt.	<a href="#">KBD_IRQSTATUS</a>	
Read the <a href="#">KBD_FULLCODE17_0</a> to <a href="#">KBD_FULLCODE80_72</a> registers (or 8 × 8 keyboard-size-supporting <a href="#">KBD_FULLCODE31_0</a> and <a href="#">KBD_FULLCODE63_32</a> registers) to determine which key matrix combination was pressed.	<a href="#">KBD_FULLCODE17_0</a> [ROWi bits] (where i = 0 to 1) up to <a href="#">KBD_FULLCODE71_54</a> [ROWi bits] (where i = 6 to 7); <a href="#">KBD_FULLCODE80_72</a> [ROWi bits] (where i = 8); (or <a href="#">KBD_FULLCODE31_0</a> [j] FULL_CODE_31_0 and <a href="#">KBD_FULLCODE63_32</a> [k] FULL_CODE_63_32 bits (where j = 0 to 31, k = 32 to 63)	
Clear the corresponding bit(s) in the interrupt-status register by writing logical 1.	<a href="#">KBD_IRQSTATUS</a>	0x1

**NOTE:** The long-key detection mode and the repeat mode cannot be used simultaneously, because they share the same interrupt status bit and are mutually exclusive. Software must ensure that only one of these modes at a time is selected.

**NOTE:** All interrupts are disabled on reset.

**NOTE:** When two events occur successively before the first event is read, the second interrupt is generated when the first interrupt is cleared. When more than two events in a row occur, the [KBD\\_IRQSTATUS\[3\] MISS\\_EVENT](#) bit is set. Software must check this bit, which is not reflected on the KBD\_CTL\_IRQ line.

**NOTE:** The keyboard controller uses a posted-write scheme to update any internal register. Software must read the pending write status bits to ensure that the next write access is not discarded because of ongoing write synchronization. For more information, see [Section 26.4.8.1, Write Registers Access](#).

### 26.5.1.2.2 Keyboard Controller Software Scanning Mode

#### 26.5.1.2.2.1 Main Sequence – Keyboard Controller Software Mode

[Table 26-15](#) describes the keyboard controller software mode.

**Table 26-15. Keyboard Controller Software Mode**

Step	Register/Bit Field/Programming Model	Value D
Deactivate the internal keyboard controller sequencer by clearing the bit.	<a href="#">KBD_CTRL[1] NSOFTWARE_MODE</a>	0b0
Enable the event interrupt by setting the bit.	<a href="#">KBD_IRQENABLE[0] IT_EVENT_EN</a>	0b1
Wait for the KBD_CTL_IRQ interrupt signal assertion. Begin the software scan when the interrupt signal is asserted:		
1) Disable all columns to drive a logical 0 on the kpd_col[8:0] output by writing 0xFF. (logical 1 bit = inactive column-row)	<a href="#">KBD_COLUMNOUTPUTS[8:0] KBC_REG</a>	0xFF
2) Drive kpd_col(i) output, (where i = 0 to 8), to 0 to capture a pressed-key-event, at the corresponding row input.	<a href="#">KBD_COLUMNOUTPUTS[i] KBC_REG</a> (where i = 0 to 8)	0b0
3) Read the KBR_LATCH bit field of the <a href="#">KBD_ROWINPUTS</a> register to determine which is the pressed key. IF: KBR_LATCH k-bit = 0 , where k = 0 to 8 Then, the corresponding k-row is connected to the column being enabled.	<a href="#">KBD_ROWINPUTS[8:0] KBR_LATCH</a>	
END IF		
Repeat steps 2) and 3) for all existing columns.	<a href="#">KBD_WAKEUPENABLE[2:0] WUP_..._ENA</a>	0x–

**NOTE:** In software mode, during the manual keyboard scan, an interrupt is generated when a pressed key is detected.

#### 26.5.1.2.3 Using the Timer

For information about programming the keyboard controller timer, see [Section 26.4.6.2, Keyboard Controller Timer](#).

#### 26.5.1.2.4 State-Machine Status Register

To see the state of the state-machine, see [Section 26.4.6.3, State-Machine Status](#).

### 26.5.1.3 Keyboard Controller Events Servicing

[Table 26-16](#) lists the keyboard controller event servicing.

**Table 26-16. Keyboard Controller Event Servicing**

Step	Register/Bit Field/Programming Model	Value
Clear all eventual previous indications of treated interrupts; write the IRQSTATUS register:	<a href="#">KBD_IRQSTATUS</a>	0x0000000F
Enable the desired sources of interrupt by writing in:	<a href="#">KBD_IRQENABLE</a>	0x0000000-
Unmask (enable) the desired sources of interrupt by writing logical 1 in the desired bit fields.	<a href="#">KBD_WAKEUPENABLE</a>	0x0000000-
When event occurs:		
Read the status register.	<a href="#">KBD_IRQSTATUS</a>	
IF: <a href="#">KBD_IRQSTATUS</a> [3] MISS_EVENT = 1	Start the interrupt handler for missed event.	
ELSIF: <a href="#">KBD_IRQSTATUS</a> [2] IT_TIMEOUT = 1	Start the interrupt handler for timeout event.	
ELSIF: <a href="#">KBD_IRQSTATUS</a> [1] IT_LONG_KEY = 1	Start the interrupt handler for long key pressed event.	
ELSIF: <a href="#">KBD_IRQSTATUS</a> [0] IT_EVENT = 1	Start the interrupt handler for pressed key event.	
ENDIF		
Wait for the execution of the corresponding interrupt handler.	Interrupt controller of the MPU	
Clear the corresponding IRQ status register bits by writing 1 there.	<a href="#">KBD_IRQSTATUS</a>	0x0000000-
Disable the corresponding sources of interrupt if needed by writing 0 at the corresponding bit fields.	<a href="#">KBD_IRQENABLE</a> or <a href="#">KBD_WAKEUPENABLE</a>	0x0000000-

## 26.6 Keyboard Controller Register Manual

### 26.6.1 Keyboard Controller Instance Summary

Table 26-17 summarizes the keyboard controller instances.

**Table 26-17. Keyboard Controller Instance Summary**

Module Name	Base Address	Size
Keyboard controller	0x4A31 C000	4KB

### 26.6.2 Keyboard Controller Registers

#### 26.6.2.1 Keyboard Controller Register Summary

Table 26-18 summarizes the keyboard controller register mapping.

## Initialization

---

---

---

This chapter introduces the steps in the general-purpose (GP) device initialization.

Topic	Page
27.1 Initialization Overview .....	5723
27.2 Preinitialization .....	5725
27.3 Reset Sequences .....	5742
27.4 Device Initialization by ROM Code .....	5743
27.5 Services for HLOS Support .....	5808

## 27.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the device from power on to OS/application execution. It provides an overview of the overall initialization process, including hardware- and software-related steps, a general overview of the ROM code operational requirements, and the behavior expectations.

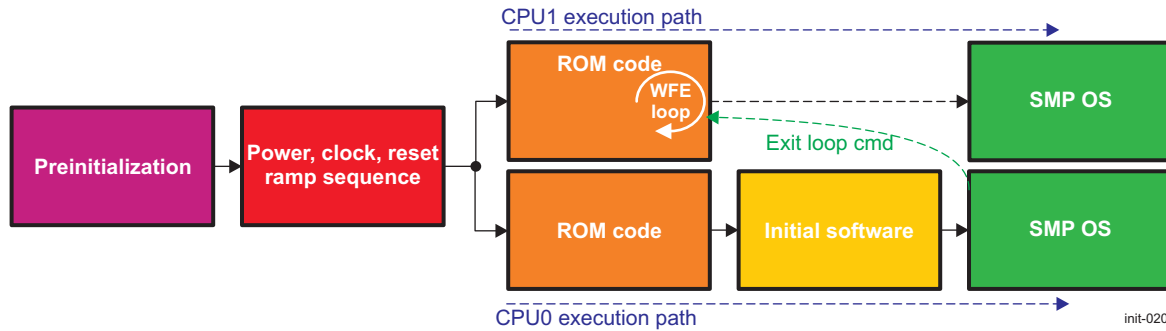

### 27.1.1 Terminology

- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase
- **Configuration Header (CH):** Optional structure, that precedes the initial software and allows the redefinition of the ROM code default settings
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code in preflashing. It also programs an image in external memories.
- **GP device:** General-purpose device
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Master CPU:** The ARM® Cortex™-A9 MPCore™ CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no software booting configuration is programmed.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM Code:** The on-chip software in OMAP™ ROM that implements booting
- **Save-And-Restore (SAR RAM) memory:** On-chip RAM memory that is not cleared after warm resets or wakeups from low-power modes
- **Slave CPU:** The ARM Cortex-A9 MPCore CPU for which CPU-ID is 1. It is brought to the wait-for-event (WFE) state by the ROM code, waiting to be woken up by the master CPU.
- **Software booting configuration:** A logical structure stored in the SAR memory that allows the redefinition of the ROM code default settings when booting after a warm reset

### 27.1.2 Initialization Process

Figure 27-1 is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power, clock, reset ramp sequence:** Specific sequence that is applied by the power-management chip
- **ROM code:** Responsible for finding/downloading and for executing the initial software by using the master CPU
- **Initial software:** Software that prepares and passes control to application software or to the high-level operating system (HLOS)
- **Symmetric multiprocessing (SMP)-capable HLOS** or application (primarily for diagnostics)

**Figure 27-1. Initialization Process**

The first two steps in the initialization process are hardware-oriented; however, they require understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these pins and the associated configuration registers that are vital to the correct initialization of the device.

## 27.2 Preinitialization

To accomplish a successful boot-up operation with a general-purpose (GP) device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the master CPU, must be connected and driven correctly to successfully initialize the device. The following sections describe the specific requirements for the preinitialization stage.

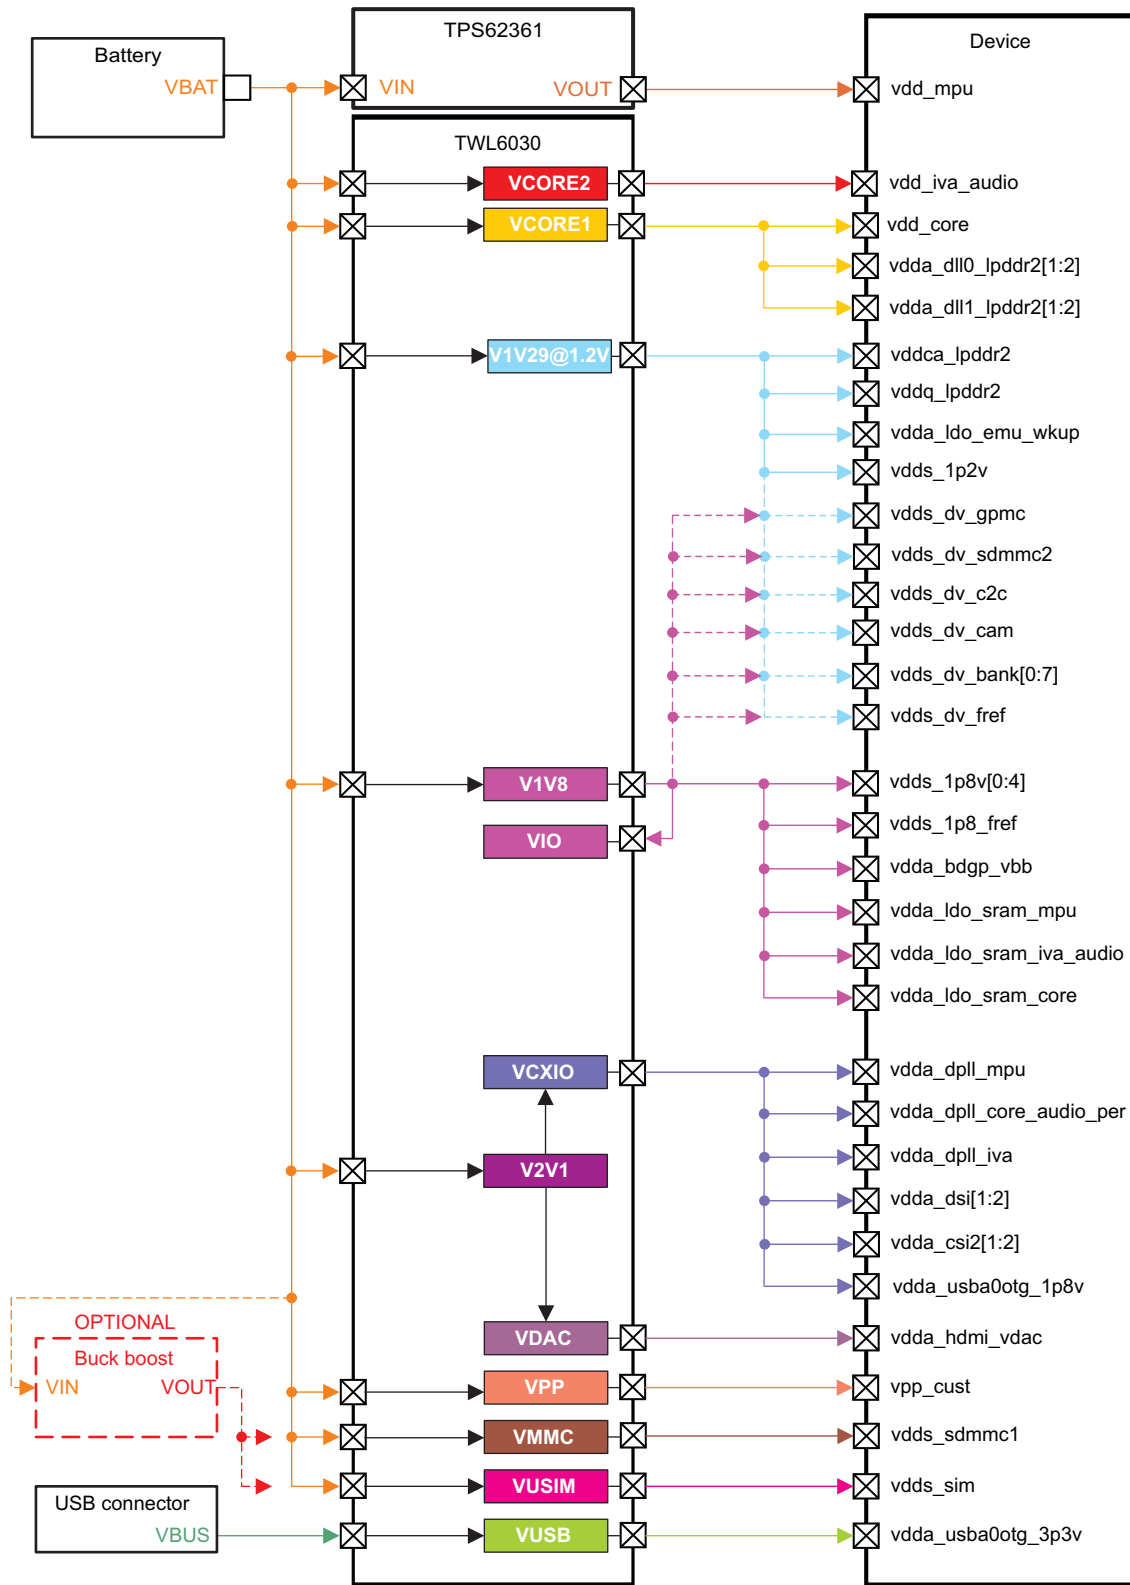

### 27.2.1 Power Requirements

The device can be supplied by an external power-management integrated circuit (IC). TI provides a global solution with the device connected to the TWL6030 power-management/TWL6040 audio codec IC.

[Figure 27-2](#) shows the power connections between the OMAP device and the TWL6030 power IC.

Figure 27-2. Power Supply Connections

init-002

**NOTE:** Figure 27-2 is an example of power connections between the device and the TWL6030. These connections depend on the actual application.

Table 27-1 describes the device power balls.

**Table 27-1. OMAP Power Balls <sup>(1)</sup>**

For more information about power management, see *Power Management Functional Description*, in [Chapter 3, Power, Reset, and Clock Management](#).

The OMAP4460 power supply structure is based on the following constraints:

- Because most of the I/Os must be powered before the core, they are supplied on a specific rail (1.2 or 1.8 V).
- MPU is supplied with additional power resource. It is controlled by SmartReflex link and a GPIO pin.
- IVA, ABE, and Core are mapped on dedicated SMPS to allow independent SmartReflex dynamic frequency and voltage scaling for each of them.
- Because the DPLL, DSI, CSI, and USB OTG interfaces are noise-sensitive power domains, they are supplied by a dedicated rail to avoid other power sinks from affecting their power rail.
- Because bandgap, BodyBias LDOs, and SRAM LDOs must be supplied at 1.8 V from the beginning of the power-up sequence up to the end of power down, they are supplied by V1V8. This also applies to the WKUP LDO at 1.2 V.
- Video DAC, eFuse VPP, SDMMC, and USB I/Os have specific requirements (sequencing, dual voltage, noise immunity, etc.) that require each of them be supplied by a dedicated power source.

### 27.2.2 Access to Power-Management IC

The ROM code accesses the power-management chip for the following purposes:

- SD/MMC1 powering:
  - The VMMC LDO is switched on by the ROM code when booting from the SD/MMC1 interface.

---

**NOTE:** The power supplies required for SD/MMC interface 2 are not controlled by the ROM code. It is assumed that the power-management chip (or the system hardware) properly powers the SD/MMC module attached to this interface.

---

- USB peripheral booting (internal or external transceiver):
  - PrevStartOk mechanism

This mechanism provides the ability to bypass the USB connection if a specific flag is set in the TWL6030 RTC domain (retained when the system is switched off).

- USB transceiver powering

The TWL6030 VUSB LDO is turned on by the ROM code.

---

**NOTE:** If TWL6030 is not present and the USB external transceiver boot is chosen, the TWL6030-related operations do not complete without blocking the USB boot procedure.

---

- USB peripheral booting (internal transceiver):

- VBUS detection

The VBUS power pad is localized on the TWL6030 power IC. As a result, the ROM code must read from a TWL6030 register to get the status reflecting the device attachment to the USB link.

- Gating the TWL6030 USB charging circuitry during a suspend scenario

If this event occurs, the ROM code should detect a suspend event and gate the charge circuitry inside the TWL6030.

---

**NOTE:** If TWL6030 and/or VBUS are not detected, the USB boot is blocked when booting from the internal transceiver, except if the USB(2) option is chosen.

---

### 27.2.2.1 Power-Management IC Detection

When booting from an SD/MMC card or USB internal transceiver (and only for these two booting options) the ROM code tries to access the power device through the inter-integrated circuit (I<sup>2</sup>C™). The first access is a read transaction to obtain the TWL6030 version register. If this read access is successful (that is, the I<sup>2</sup>C transaction is acknowledged), the ROM code considers that a power-management device is attached, assuming it is TWL6030. The version value read is not used in any computation or compared to any hardcoded value.

If the first read transaction fails (that is, the I<sup>2</sup>C transaction times out or is not acknowledged), the ROM code logs it into a flag and does not try any further transaction until the next reset cycle. In this case, the nondetection of the companion chip does not block the SD/MMC1 boot process. However, the MMC card boot procedures do not work as defined in this document. In particular, The ROM code does not ensure that the SD/MMC1 interface is powered when accessing the memory contents.

The nondetection of the power-management IC blocks the USB internal transceiver boot, except when USB(2) booting mode is chosen.

An alternate way to boot from the USB internal transceiver without the TWL6030 and with the USB(1) booting option is to have the alternate power-management IC match (or emulate) at least read the P1, P2, and P8 commands (see [Section 27.2.2.2, Summary of the I<sup>2</sup>C Transactions](#)).

If TWL6030 is not present, but the USB(2) option is chosen, or registers are emulated, the following functions are not ensured to work:

- The PrevStartOk mechanism is not functional (the specific flag is not checked).
- The ROM code does not ensure that the VUSB power is applied to the USB transceiver.
- Peripheral booting from the internal USB transceiver is not ensured to be functional, because the VBUS state read transaction is not performed.
- The ROM code does not support the suspend scenario during USB peripheral boot from the internal transceiver.

From the ROM code perspective, nothing prevents the use of another power IC together with the OMAP4460. However, special care must be taken if considering the two previously mentioned booting options (SD/MMC1 or USB internal transceiver).

[Table 27-2](#) summarizes the USB booting options according to TWL6030 presence.

**Table 27-2. USB Booting Options**

Booting Option	TWL6030 Detected	TWL6030 Emulated	Description
USB(1)	Yes	N/A	Full USB booting
USB(1)	No	Yes	ROM code does not ensure VUSB, VBUS, PrevStartOk, or suspend mode.
USB(1)	No	No	USB booting is not possible.
USB(2)	Yes	N/A	Full USB booting
USB(2)	No	Yes	ROM code does not ensure VUSB, VBUS, PrevStartOk, or suspend mode.
USB(2)	No	No	ROM code does not ensure VUSB or VBUS. PrevStartOk and suspend mode are not supported.
USB-ULPI	Yes	N/A	ROM code does not ensure VUSB or VBUS. PrevStartOk is supported. Suspend mode is not supported.
USB-ULPI	No	Yes	ROM code does not ensure VUSB, VBUS, or PrevStartOk. Suspend mode is not supported.
USB-ULPI	No	No	ROM does not ensure VUSB or VBUS. PrevStartOk and suspend mode are not supported.

### 27.2.2.2 Summary of the I<sup>2</sup>C Transactions

The ROM code accesses the power-management chip through the I2C1 interface. [Table 27-3](#) summarizes the list of accesses.

**Table 27-3. Register Accesses to PMIC**

ID	I <sup>2</sup> C Address	Register Address	TWL6030 Register	Access Type	Value	Transaction Condition
P1	0x4A	0x87	JTAGVERNUM	R	0x-	Booting from MMC1, USB, or USB-ULPI
P2	0x48	0x2B	PHOENIX_SEQ_CFG	R/W	0x-/0x00	Booting from USB or USB-ULPI
P3	0x48	0x9B	VMMC_CFG_VOLTAGE	W (ORed) <sup>(1)</sup>	0x15	Booting from MMC1
P4	0x48	0x9A	VMMC_CFG_STATE	W (ORed) <sup>(1)</sup>	0xE1	Booting from MMC1
P5	0x48	0xA3	VUSB_CFG_VOLTAGE	W (ORed) <sup>(1)</sup>	0x18	Booting from USB or USB-ULPI
P6	0x48	0xE5	MISC2	W	0x08	Booting from USB or USB-ULPI
P7	0x48	0xA2	VUSB_CFG_STATE	W	0xE1	Booting from USB or USB-ULPI
P8	0x49	0xE3	CONTROLLER_STAT1	R	0x-	Booting from USB or USB-ULPI
P9	0x49	0xE8	CHARGERUSB_CTRL1	W	0x80	Booting from USB

<sup>(1)</sup> (1) The register is not blindly overwritten but is first read and then ORed with the specified value.

#### Transaction description

P1: JTAGVERNUM: Power-management IC detection. There must be a register at this location; however, its value is not used further by ROM code.

P2: PHOENIX\_SEQ\_CFG: The PrevStartOk flag is checked when performing USB peripheral boot (internal or external transceiver). If the flag is set, the USB peripheral booting procedure is skipped. In any case the full register is cleared (write 0x00) after the read transaction.

P3: VMMC\_CFG\_VOLTAGE: For the sake of powering the SDMMC1 card cage, the VMMC\_CFG\_VOLTAGE and VMMC\_CFG\_STATE registers are configured to set the VMMC LDO to 3 V. The value 0x15 is written to the VMMC\_CFG\_VOLTAGE register (selects 3-V output).

P4: VMMC\_CFG\_STATE: The value 0xE1 is written to the VMMC\_CFG\_STATE register (applies to all register groups, LDO state switched on).

P5: VUSB\_CFG\_VOLTAGE: The USB OMAP internal transceiver must be powered with a 3.3-V source to ensure its correct functionality. Three registers are used for this purpose. The VUSB\_CFG\_VOLTAGE register is written the value 0x18 for selecting 3.3 V.

P6: MISC2: The MISC2 register is written the value 0x08 for selecting the VBUS source.

P7: VUSB\_CFG\_STATE: The VUSB\_CFG\_STATE register is written the value 0xE1 for switching the VUSB LDO on for all register groups.

P8: CONTROLLER\_STAT1: VBUS detection is performed by reading the VBUS\_DET bit from the CONTROLLER\_STAT1 register. If this bit is set, it reflects that a USB cable is plugged.

P9: CHARGERUSB\_CTRL1: This register is written the value 0x80 (SUSPEND\_BOOT = 1) for gating the charge circuitry when getting a USB SUSPEND event. If this bit is not set, the USB boot is aborted.

The complete description of the TWL6030 register map is in TWL6030 documentation.

---

**NOTE:** No specific action is performed regarding the TWL6030 primary watchdog feature. In particular, if it is active (configurable in EEPROM) in the companion device, a system reset may occur before ROM code completes. The elapse value for the reset must be appropriately tuned so that the ROM code is not interrupted before the full platform start up (that is, before the initial software can take a specific action).

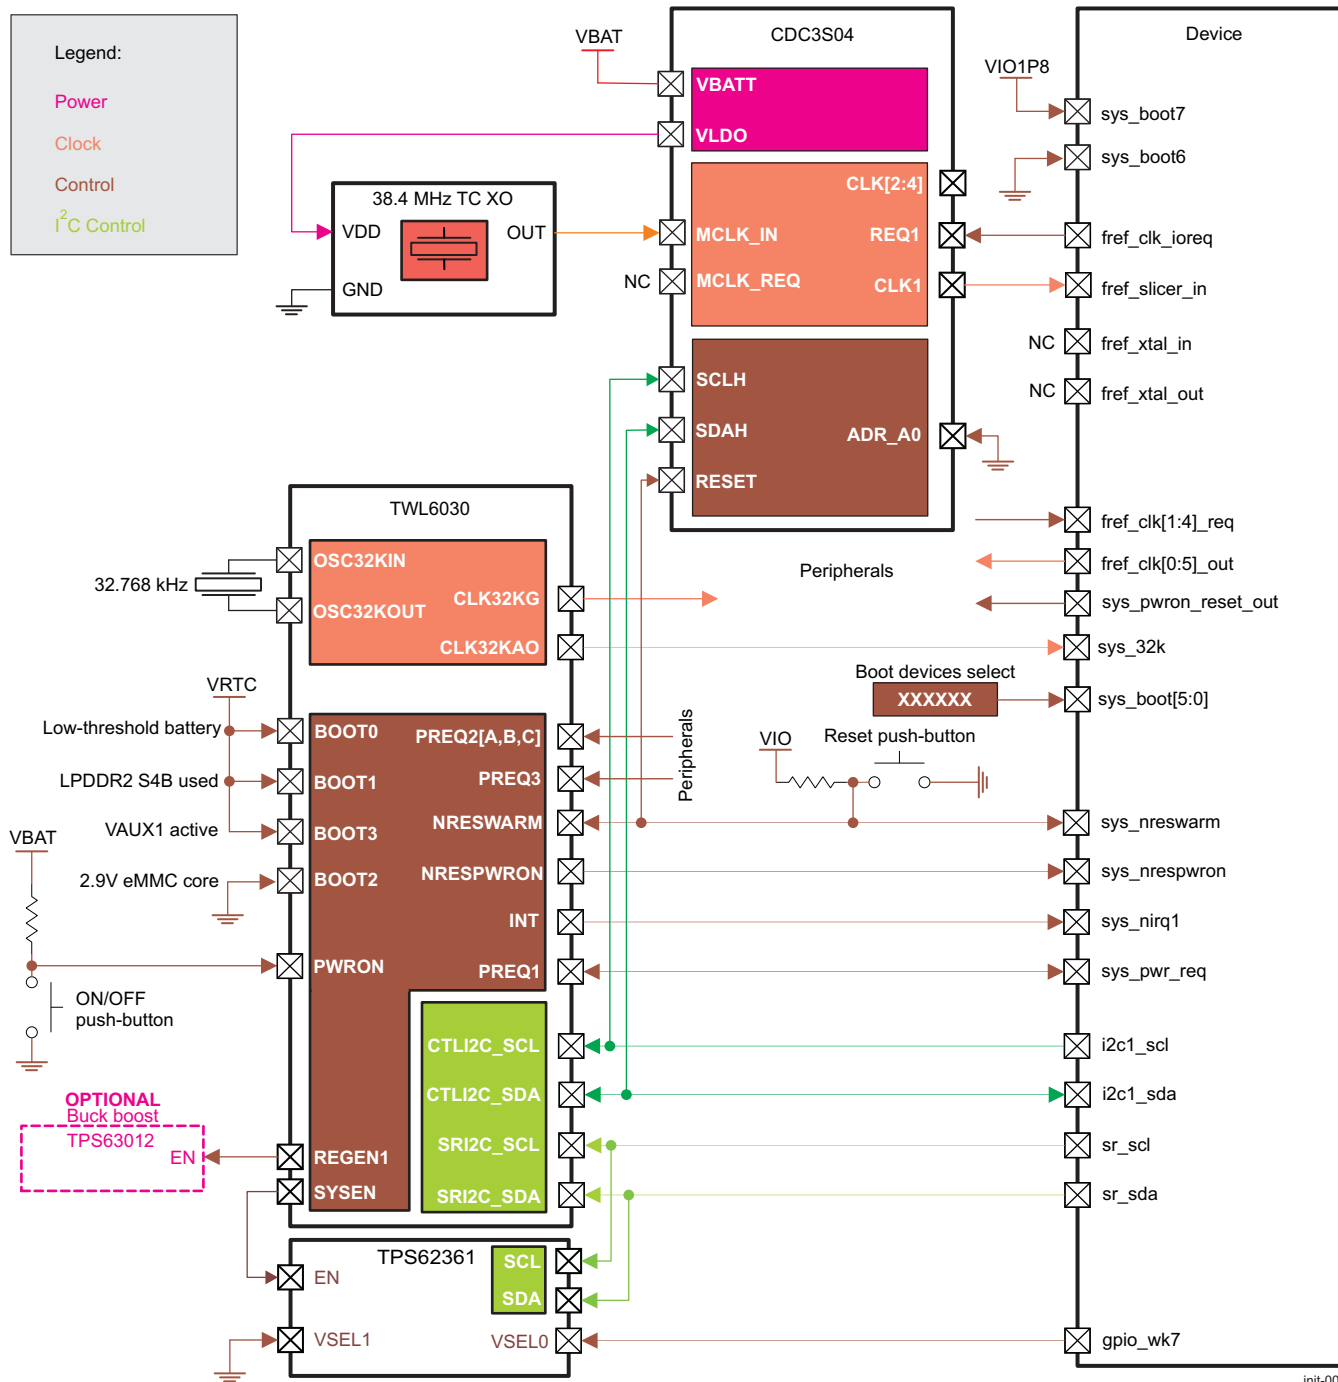

---

## 27.2.3 Clock, Reset, and Control

### 27.2.3.1 Overview

Figure 27-3 shows the clock and reset environment that gathers the clocks and reset-related signals at the system level, and the system-expansion signals.

Figure 27-3. Clock, Reset and Control Environment

The main features of the system interface are:

- A clock request output to an external clock source
- 12-, 16.8-, 19.2-, 26-, or 38.4-MHz reference clock input from external oscillator or clock supplied using

internal crystal oscillator (up to 20 MHz)

- 32-kHz CMOS clock input
- Six configurable output clocks
- Eight input signals to define the boot mode and device system clock source
- Two reset sources
  - Power-on reset (POR) (cold reset)
  - Bidirectional warm reset

### 27.2.3.2 Clocking Scheme

#### 27.2.3.2.1 Required System Input Clocks

The device operation requires external input clocks, as follows:

- 32k clock: A 32.768-kHz crystal is connected to the TWL6030 device that embeds the 32k-oscillator (a square CMOS clock can also be delivered on the 32k\_xtalin pin if the 32k-crystal is connected on another device of the system). The resulting 32k clock is delivered to the entire system on three outputs:
  - CLK32KAO\_is always on (meaning that when TWL6030 VIO is on; that is, it is in WAIT-ON or ACTIVE state). It is used to deliver a 32k clock to always-on features, such as the OOMAP4460 and modem in the described system.
  - CLK32KG is software-controlled and is delivered when requested by the OMAP4460 (this input is on by default at platform boot).
  - CLK32KAUDIO is software-controlled and is delivered to the TWL6040 audio device (not shown in [Figure 27-3](#)) when requested by the OMAP4460 (this input is on by default at platform boot).
- High-speed clock: The platform high-speed (HS) low-jitter sine clock is provided by the clock driver (CDC3S04) to the TWL6040 audio IC, OMAP, and other peripherals requesting low-jitter sine clock (up to three outputs are available for peripherals). The OMAP device delivers digital clocks to other peripherals. The OMAP4460 supports different flavors of clock sources at several frequencies:
  - Crystal source. An internal oscillator embedded in the OMAP4460 is used. In this mode, the input clock is limited to 20 MHz by oscillator construction. The `fref_clk_ioreq` is then set as an input to be used by an external device to request the OMAP4460 to deliver the clock on `fref_clk0_out`. The `fref_slicer_in` pin can then be used to input an auxiliary clock (mainly for debugging purposes).
  - External oscillator type source. The internal OMAP4460 oscillator is disabled. The external source delivers a sine (slicer active) or square (slicer bypassed) single-ended clock on the `fref_slicer_in` pin. The external source is enabled by the `fref_clk_ioreq` output. `fref_xtal_in` can then be used to input an auxiliary clock (oscillator-bypass mode).
- Audio clock: The TWL6040 audio device builds its own clock, either from the 32k clock or the HS clock (depending on the audio scenario). This internal clock is delivered to the OMAP4460 ABE subsystem (`abe_clks` input) for audio flow synchronization.

Clock input modes are selected by the `sysboot` pin (`sys_boot[6:7]`) to allow the system to wake up in the proper mode, even after a cold boot (selection of the relevant input pin [`fref_slicer_in` or `fref_xtal_in/out`] and slicer/oscillator mode setting [on or bypass]).

The OMAP4460 provides the HS clock to other devices through six `fref_clk[0:5]_out` pins.

TWL6040 audio device receives the HS clock on the MCLK pin when the audio scenario requires it (some low-power audio player scenarios can be performed only with the 32k clock).

[Table 27-4](#) lists the mapping for the OMAP clock input sources. [Table 27-5](#) lists the TWL6030 clock requirements.

**Table 27-4. Mapping for Input Sources**

Input Source	Mapping	Frequency Range/List	Type
Internal oscillator	<code>fref_xtal_in/fref_xtal_out</code>	12, 16.8, or 19.2 MHz	Crystal connection pins
External HS clock	<code>fref_slicer_in</code>	12, 16.8, 19.2, 26, or 38.4 MHz	Sine or square single ended

**Table 27-4. Mapping for Input Sources (continued)**

Input Source	Mapping	Frequency Range/List	Type
External 32k clock	sys_32k	32.768 kHz (nom.)	Square
TWL6040 audio IC	abe_clks	<19.2 MHz	Square

**Table 27-5. TWL6030 Clock Requirements**

Input Source	Mapping	Frequencies Range/List	Type
Internal oscillator	OSC32KIN/OSC32KOUT	32.768 kHz (nom.)	Crystal connection pins

**CAUTION**

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production.

**27.2.3.2.2 Optional System Output Clocks**

The OMAP device can output six alternate clocks, `fref_clk[0:5]_out`. Output clocks 1 through 4 can be gated or enabled through associated clock-request signals, `fref_clk[1:4]_req`.

The clocks can be managed by software with the appropriate register in the power, reset, and clock management (PRCM) module. For more information, see [Section 3.3, PRCM Subsystem Environment](#).

**27.2.3.3 Reset Configuration****27.2.3.3.1 ON/OFF Interconnect and Power-On-Reset**

The entire system is typically awakened by an ON/OFF push button connected to the TWL6030 power IC. This signal belongs to the VBAT power domain and is active low (the TWL6030 internal pullup ties it to VBAT). Power up is propagated to the OMAP4460 through NRESPWRON/sys\_nrespwron signals when the TWL6030 power-up sequence is achieved. Because this signal is also provided to the TWL6040 audio IC, it resets its state-machine and gets some available functions even if the V2V1 power supply is not provided.

**27.2.3.3.2 Warm Reset**

A warm reset can be asserted by the OMAP4460, by an external button (typically for development platform), or by any other device connected to it. It is mainly used to propagate the OMAP4460 internal reset to the whole platform to set it to a known state.

The OMAP4460 releases `sys_nreswarm` after NRESPWRON is deasserted.

**27.2.3.3.3 Peripheral Reset by `sys_pwron_reset_out`**

`Sys_pwron_reset_out` is provided to the system by the OMAP4460 to power on and/or deactivate the reset of system peripherals. This signal is activated by SCRMP during the power-up sequence a few milliseconds after the default-on clocks (OMAP4460 – `fref_clk4_out` and CDC3S04 – `CLK[1:4]`) are stabilized. This allows switching on peripherals that require synchronous reset.

`Sys_pwron_reset_out` is controllable by software when the system is on. It is not affected by a warm reset.

**27.2.3.3.4 Peripheral Reset by GPIO**

Most of the peripherals are reset/power on/off by GPIO. By default, under POR, most OMAP4460 signals are in safe mode with a default value driven by the I/O cell. The value is driven by an internal pullup or pulldown. Depending on the peripheral reset active level, users must select one GPIO or another (according to the reset value).

Once POR is released, the value on the pad is driven by the default configuration of control module. Most of time, this configuration is aligned with the default value selected on the I/O cell.

The next step is application-dependent: Users must configure the OMAP4460 registers to validate GPIO use and the default configuration of the control module.

### 27.2.3.3.5 Warm Reset Impact on GPIOs

When a warm reset event occurs:

- The GPIO controller is reset. Consequently, the GPIO is automatically turned in input mode.
- The control module is not reset. Information related to signal multiplexing mode and pullup or pulldown configuration is still valid.

Therefore, when a warm reset event happens, the output buffer is disabled. Consequently, to avoid getting a floating signal during (and after) a warm reset event and to keep the same value that was driven before the reset, users must align the pull value with the drive value each time there is an access to a dedicated GPIO register.

---

**NOTE:** Failing to align pulls with the buffer driving value (for example, pullup enabled with buffer driving low) will cause unnecessary power consumption.

---

**NOTE:**

- For more information about device reset management, see [Section 3.5, Reset Management Functional Description](#) in [Chapter 3, Power, Reset, and Clock Management](#).
  - To determine the cause of the last reset, see [Section 3.5.5, Reset Logging](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- 

### 27.2.3.4 TWL Power/Audio Devices Control

- I<sup>2</sup>C:

The TWL6030 power and TWL6040 audio devices are controlled by the OMAP4460 I2C1 (HS I<sup>2</sup>C). Some internal pullup resistors are provided by the OMAP4460 (different values can be selected to adapt the I/O buffer strength to the bus topology). The I<sup>2</sup>C links must first be started in fast-speed mode. Therefore, the buffer default pullup value must support this mode.

- SmartReflex control:

Some of the TWL6030 power resources are controlled through SmartReflex link (I<sup>2</sup>C-like). This control allows the host to drive the dynamic voltage frequency scaling (DVFS) and adaptive voltage scaling (AVS) operations of these resources. As with its I<sup>2</sup>C interfaces, some internal pullup resistors are provided on the OMAP4460 SmartReflex I/Os. The link must be run at the highest speed allowed by the voltage controller of the OMAP4460 (lower than I<sup>2</sup>C HS mode frequency). For example, this frequency must be 1.82 MHz with a 38.4-MHz system clock.

- INT:

Both devices can activate the INT signal at any time when they require the host device to monitor their activity. When receiving such an interruption, the OMAP4460 checks, through the I<sup>2</sup>C, to determine the source of the interrupt. These INT pins are active low.

- Sys\_pwr\_req:

When exiting off mode, the OMAP4460 ties up the sys\_pwr\_req pin to wake up the TWL6030 power application group.

### 27.2.3.5 TWL6030 Power Request Signals

The TWL6030 power-management IC drives three external enable-output signals. This allows switching on some external resources at different stages of the power-up sequence:

- REGEN1/2 are driven high at the beginning of the power-up sequence, before any internal power source is turned on. They belong to the VBAT power domain. REGEN1 can typically be used for buck

boost control.

- SYSEN is driven high immediately after the VCORE power output is turned on. It allows switching on the additional power regulator to supply the MPU subsystem. SYSEN belongs to the VIO power domain.

TWL6030 power also receives five power resource requests: PREQ[1, 2A, 2B, 2C, 3]. These pins allow an external device to request TWL6030 power internal resources. TWL6030 power behavior when pins are activated must be programmed after the first boot (resources and PREQ pins allocated by group, resource behavior upon group activation, etc.). The typical PREQ allocation per group is:

- PREQ1: Application group. Connected to OMAP.
- PREQ2A, PREQ2B, and PREQ2C: Peripheral group. Connected to peripherals A, B, and C (for instance, Bluetooth®/FM/GPS/WLAN device, Wimax device, W-USB device).
- PREQ3: Modem group

---

**NOTE:** Powering the clock driver requires PREQ assertion. Therefore, it is advised to connect any peripheral receiving a clock from CDC3S04 to one PREQ.

---

The use of PREQ[1:3] is especially required when TWL6030 is in sleep mode, because it cannot handle an I<sup>2</sup>C command. Any device that requires the TWL6030 resource to wake up must first activate its associated PREQ. All TWL6030 power regulators are off or in sleep mode when TWL6030 is in sleep mode.

PREQ1 is used by OMAP when waking up from off mode to wake up the TWL6030.

## 27.2.4 Boot Configuration

Six external pads (sys\_boot[5:0]) are used to select interfaces or devices for the booting list. The sys\_boot[7:6] pads select the OMAP clock source configuration.

All eight pins are sampled and latched onto the SYSCTRL\_GENERAL\_CORE.CONTROL\_STATUS[7:0] SYS\_BOOT register bit field after POR. After booting, these pads can be used for other functions such as GPIOs, and the associated register bit field is not updated by the new functionality. For more information about pad multiplexing configuration, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#).

---

**NOTE:**

- If used as GPIOs, sys\_boot[7:0] pads must be used only in output mode to ensure that the input values are selected by the pullups and pulldowns after POR.
  - Unlike sys\_boot[5:0] pads, sys\_boot[7:6] pads have no internal pullups or pulldowns automatically selected at POR. The sys\_boot[5:0] pads have selected pulldowns at that moment. To avoid leakage, care must be taken to disable the pulldown in case the respective pad has external connection to VIO (= 1). See the appropriate register fields in [Chapter 18, Control Module](#).
- 

### 27.2.4.1 System Clock Source Selection

[Figure 27-4](#) is an overview of the system clock selection. [Table 27-6](#) summarizes the selection.

Figure 27-4. System Clock Selection Diagram

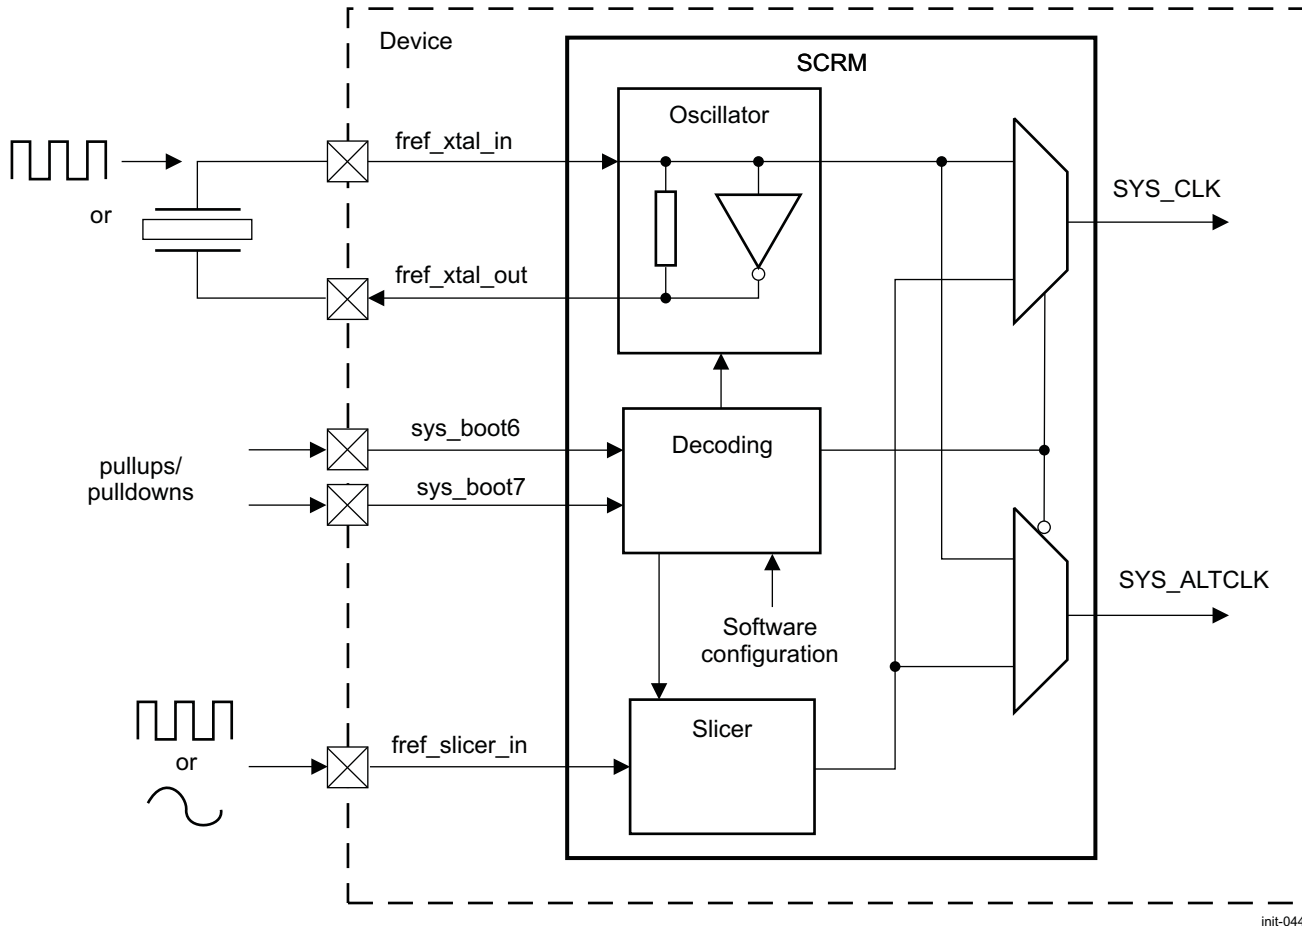

Table 27-6. System Clock Selection Summary

sys_boot[7:6]	SYS_CLK Source	SYS_ALTCLK Source	Oscillator Mode	Slicer Mode	fref_clk_ioreq Mode
0b00	fref_xtal_in	fref_slicer_in	Active	Power-down	Input
0b01	fref_xtal_in	fref_slicer_in	Bypass	Power-down	Output
0b10	fref_slicer_in	fref_xtal_in	Power-down	Active	Output
0b11	fref_slicer_in	fref_xtal_in	Power-down	Bypass	Output

OMAP4460 clock source settings description:

- sys\_boot[7:6] = 0b00:
  - The system clock source is the on-chip oscillator.
  - The slicer is powered down and its input can be used to provide the OMAP with an alternate clock.
  - Fref\_clk\_ioreq is a clock request input associated to fref\_clk0\_out by default.
- sys\_boot[7:6] = 0b01:
  - The system clock source is external. The internal oscillator is bypassed to inject the system clock.
  - The slicer is powered down and the slicer input can be used to provide the chip with an alternate clock.
  - The Fref\_clk\_ioreq signal is an output that requests the clock to the external clock supplier.
- sys\_boot[7:6] = 0b10:
  - The system clock source is the on-chip slicer, supplied by an external oscillator. The internal

oscillator is powered down and the input can be configured to supply the alternate system clock to OMAP device.

- The slicer is active.
- The Fref\_clk\_ioreq signal is an output that requests the clock from the external clock supplier.
- sys\_boot[7:6] = 0b11:
  - The system clock source is external. The internal oscillator is powered down and the input can be configured to supply the alternate system clock to the OMAP device.
  - The slicer is bypassed to inject the system clock.
  - The Fref\_clk\_ioreq signal is an output that requests the clock from the external clock supplier.

#### 27.2.4.2 Booting Device Order Selection

The ROM code creates the device list (order) based on information gathered from two locations.

- The first location is the software booting configuration stored in the nonvolatile SAR memory, and used after warm resets.
- The second location is the sys\_boot[5:0] external configuration pins sensed in the control module.

The SYSBOOT pins are used to index a booting device list from a table with possible booting scenarios. The order of examined booting devices is from the first to the fourth devices.

The following names are used in the tables:

- Memory types:
  - Execute in place (XIP): XIP memory without wait-signal monitoring enabled (NOR flash memory or other XIP device)
  - XIP wait: XIP memory with wait-signal monitoring
  - NAND: NAND flash memories (non-XIP)
  - OneNAND: OneNAND and Flex-OneNAND flash memories
  - MMC1: MMC/SD card or eMMC™/eSD™ device (SD/MMC port 1)
  - MMC2(1): eMMC or eSD memory device, first option (SD/MMC port 2). See [Section 27.2.4.3, Boot Peripheral Pin Multiplexing](#).
  - MMC2(2): eMMC or eSD memory device, second option (SD/MMC port 2). See [Section 27.2.4.3, Boot Peripheral Pin Multiplexing](#).
- Peripheral interfaces:
  - USB(1): USBA0 from OMAP internal transceiver (USBPHY)
  - USB(2): USBA0 from OMAP internal transceiver (USBPHY). Allows USB booting even when no power-management IC is detected. See [Section 27.2.2.1, Power-Management IC Detection](#).
  - USB-ULPI: USBA0 from external transceiver through ULPI interface
  - Universal asynchronous receiver/transmitter (UART): UART3 interface
- Permanent booting devices listed in [Table 27-7](#) are in **bold**.

---

**NOTE:** Only permanent booting devices (in bold) are put on in the list in case of a warm reset, and the device list is taken from the sys\_boot pins. As a result, peripheral booting devices are skipped when the OMAP4460 restarts from warm resets.

---

Users can force the execution of the peripheral booting procedure after warm reset by using the software booting configuration feature.

[Table 27-7](#) lists the booting device order when it is preferred to boot from a memory type device. This table is selected by ROM code when the sys\_boot5 pin is tied high (= 1) after reset and before booting completes. If fast XIP booting is selected, the sys\_boot5 pin controls the XIP wait-signal monitoring (that is, a logical high level enables wait-signal monitoring).

**Table 27-7. Memory Preferred Booting**

sys_boot[5:0]	Booting Devices Order			
	1 <sup>st</sup>	2 <sup>nd</sup>	3 <sup>rd</sup>	4 <sup>th</sup>
0b100000	<b>MMC2(1)</b>	USB(1)		
0b100001	<b>XIP</b>	USB(1)		
0b100010	<b>XIPWAIT</b>	USB(1)		
0b100011	<b>NAND</b>	USB(1)		
0b100100	<b>XIPWAIT</b>	USB(1)		
0b100101	<b>MMC1</b>	USB(1)		
0b100110	<b>OneNAND</b>	USB(1)		
0b100111	<b>OneNAND</b>	<b>MMC2(1)</b>	USB(1)	
0b101000	<b>MMC2(1)</b>	UART		
0b101001	<b>OneNAND</b>	<b>MMC2(1)</b>	USB(2)	
0b101010	<b>XIPWAIT</b>	UART		
0b101011	<b>NAND</b>	UART		
0b101100	<b>NAND</b>	USB(2)		
0b101101	<b>MMC1</b>	UART		
0b101110	<b>OneNAND</b>	UART		
0b101111	<b>MMC2(1)</b>	USB-ULPI		
0b110000	<b>XIP</b>	USB-ULPI		
0b110001	<b>XIPWAIT</b>	USB-ULPI		
0b110010	<b>NAND</b>	USB-ULPI		
0b110011	<b>MMC1</b>	USB(2)		
0b110100	<b>MMC1</b>	USB-ULPI		
0b110101	<b>OneNAND</b>	USB-ULPI		
0b110110	<b>MMC2(1)</b>	USB(1)	UART	MMC1
0b110111	<b>XIP</b>	USB(1)	UART	MMC1
0b111000	<b>MMC2(2)</b>	USB-ULPI	UART	
0b111001	<b>NAND</b>	USB(1)	UART	MMC1
0b111010	<b>MMC2(2)</b>	UART		
0b111011	<b>MMC1</b>	USB(1)	UART	
0b111100	<b>MMC2(2)</b>	USB(1)		
0b111101	<b>MMC2(2)</b>	USB(2)		
0b111110	Reserved			
0b111111 (Only on GP devices)	<b>Fast XIP booting. Wait monitoring ON</b>	USB(1)	UART	

**Table 27-8** lists the booting device order when it is preferred to boot from a peripheral-type device. This table is selected by ROM code when the sys\_boot5 pin is tied low (= 0). If fast XIP booting is selected, the sys\_boot5 pin controls the XIP wait-signal monitoring (that is, a logical low level disables wait-signal monitoring).

**Table 27-8. Peripheral Preferred Booting**

sys_boot[5:0]	Booting Devices Order			
	1 <sup>st</sup>	2 <sup>nd</sup>	3 <sup>rd</sup>	4 <sup>th</sup>
0b000000	USB(1)	<b>MMC2(1)</b>		
0b000001	USB(1)	<b>XIP</b>		
0b000010	USB(1)	<b>XIPWAIT</b>		
0b000011	USB(1)	<b>NAND</b>		
0b000100	USB(1)	<b>XIPWAIT</b>		
0b000101	USB(1)	<b>MMC1</b>		
0b000110	USB(1)	<b>OneNAND</b>		
0b000111	USB(1)	<b>OneNAND</b>	<b>MMC2(1)</b>	
0b001000	UART	<b>MMC2(1)</b>		
0b001001	UART USB(2)	<b>OneNAND</b>	<b>MMC2(1)</b>

0b011001	USB(1)	UART	<b>MMC1</b>	<b>NAND</b>
0b011010	UART	<b>MMC2(2)</b>		
0b011011	USB(1)	UART	<b>MMC1</b>	
0b011100	USB(1)	<b>MMC2(2)</b>		
0b011101	USB(2)	<b>MMC2(2)</b>		
0b011110			Reserved	
0b011111 (Only on GP devices)	<b>Fast XIP booting. Wait monitoring OFF</b>	USB(1)	UART	

### 27.2.4.3 Boot Peripheral Pin Multiplexing

Table 27-9 lists the code pin multiplexing configuration supported by ROM according to boot peripheral.

**Table 27-9. Pin Multiplexing According to Boot Peripheral**

Boot Device	Boot Interface	Pads
NAND/OneNAND	GPMC	GPMC pads in mux mode 0, CS0, WAIT0
XIP memory	GPMC	GPMC pads in mux mode 0, CS0, WAIT0
MMC/SD/eMMC/eSD	SDMMC1	SDMMC1 pads in mux mode 0
eMMC/eSD	SDMMC2 (option 1) SDMMC2 (option 2)	GPMC pads in mux mode 1 SDMMC5 and FREF_CLK pads, all in mux mode 5
UART	UART3	UART3 pads in mux mode 0

**Table 27-9. Pin Multiplexing According to Boot Peripheral (continued)**

<b>Boot Device</b>	<b>Boot Interface</b>	<b>Pads</b>
USB from internal transceiver	HSUSBOTG (USBA0-USBPHY)	USBA0_OTG pads in mux mode 0
USB from external transceiver	HSUSBOTG (USBA0-ULPI)	DPM_EMU[2:13] pads in mux mode 1

---

**NOTE:** The ROM code examines the interfaces that are selected to be searched until a valid bootable interface/device is found. The activities on the pads of the searched interfaces must be considered in case they are connected to any other peripherals for any other purposes (for example, an LED connected to a GPMC pad muxed internally to a GPIO).

---

### 27.3 Reset Sequences

For the description of the reset sequences, see [Section 3.5.6, Reset Sequences](#), in [Section 3.5, Reset Management Functional Description](#).

## 27.4 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

### 27.4.1 Booting Overview

#### 27.4.1.1 Booting Types

Booting is the process of starting a bootstrap from one of the booting devices.

The ROM code has two functions for booting: Peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burnt, a software (warm) reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after a cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (USB or UART) by using the `sys_boot[5:0]` pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

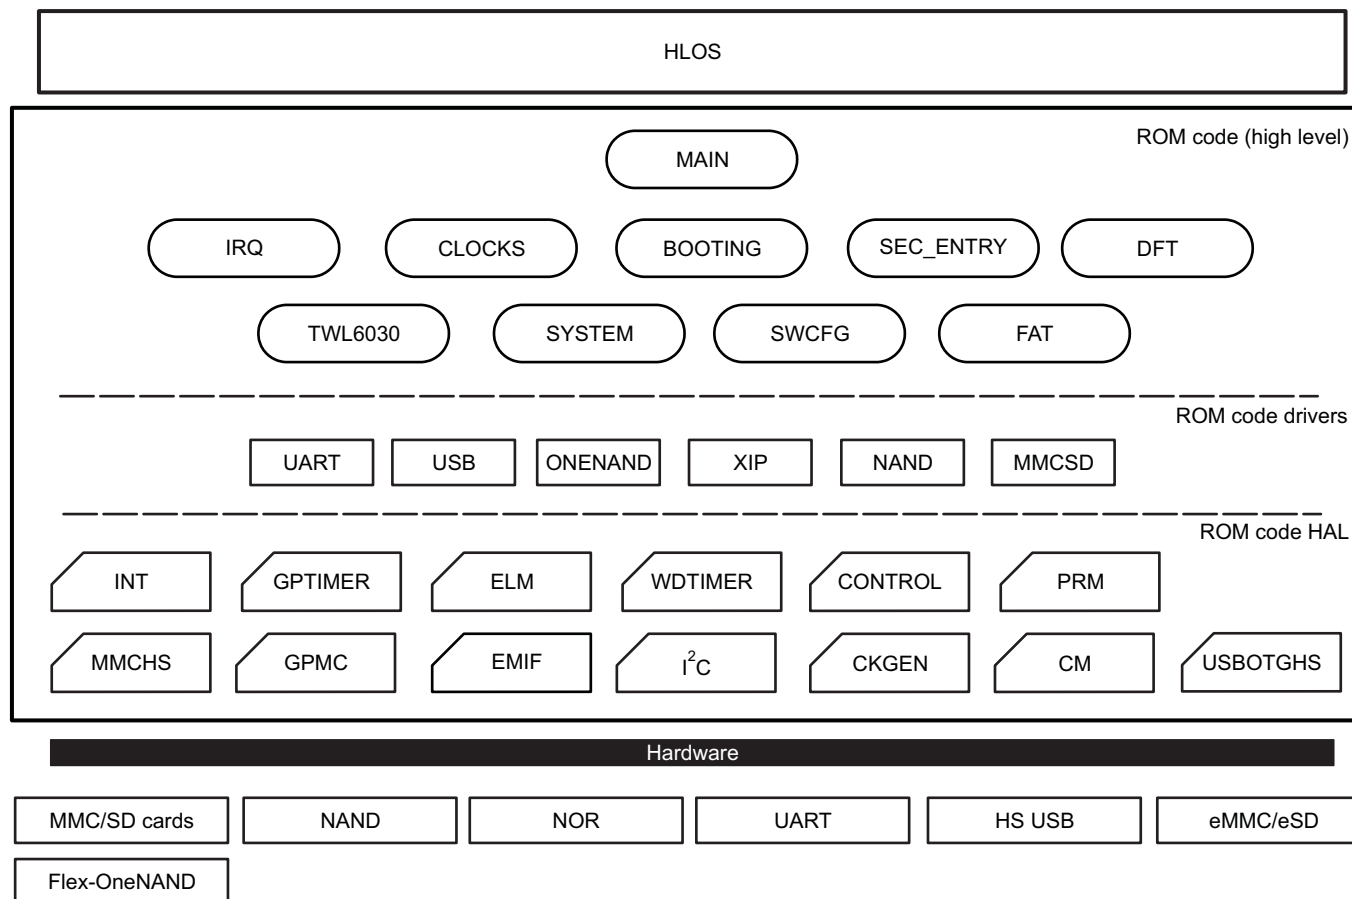

#### 27.4.1.2 ROM Code Architecture

[Figure 27-5](#) shows the ROM code architecture. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower-level layer through a unified interface.

- The high-level layer performs the main tasks of the public ROM code: multicore startup, watchdog and clock configurations, interrupt management, interaction with the power-management IC, and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to the device I/O pads.

[Figure 27-5](#) shows the three layers with their modules.

Figure 27-5. ROM Code Architecture

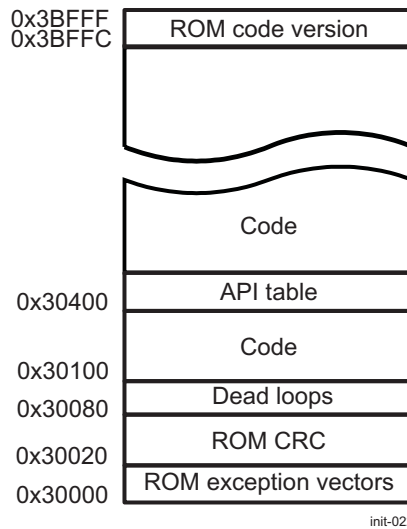

init-006

## 27.4.2 Memory Maps

### 27.4.2.1 ROM Memory Map

Figure 27-6 shows the 48-KB ROM memory map.

**Figure 27-6. ROM Memory Map**

- ROM exception vectors  
Exceptions are redirected to ROM exception vectors (see [Table 27-10](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses to the PC register.

**Table 27-10. ROM Exception Vectors**

Address	Exception	Content
0x30000	Reset	Branch to the ROM code startup
0x30004	Undefined	PC = 0x4030 D004
0x30008	Software interrupt (SWI)	PC = 0x4030 D008
0x3000C	Prefetch abort	PC = 0x4030 D00C
0x30010	Data abort	PC = 0x4030 D010
0x30014	Unused	PC = 0x4030 D014
0x30018	IRQ	PC = 0x4030 D018
0x3001C	FIQ	PC = 0x4030 D01C

- ROM code cyclic redundancy check (CRC)  
The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 0x30000–0x3BFFF. The 4-byte CRC code is stored at location 0x30020.
- Dead loops  
Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see [Table 27-11](#)).

**Table 27-11. Dead Loops**

Address	Purpose
0x30080	Undefined exception default handler
0x30084	SWI exception default handler
0x30088	Prefetch abort exception default handler
0x3008C	Data abort exception default handler
0x30090	Unused exception default handler
0x30094	IRQ exception default handler
0x30098	FIQ exception default handler

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked to RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 0x300C0. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code

This space is used to hold code and constant data.

- API table

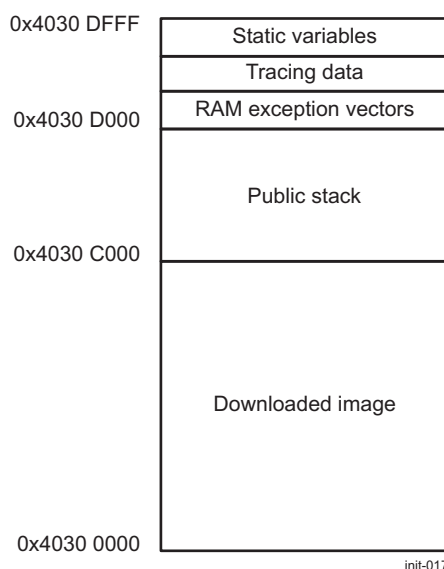

The purpose of this table is to allow external code access to system maintenance, utility, and device driver functions which are used for ensuring the ROM code boot functionality. These functions can be reused at run time by calling a fixed address hardcoded in this table.

- ROM code version

The ROM code version consists of two decimal numbers: major and minor. It can be used to identify the ROM code release version burnt in a given IC (for example, useful during a debugging session). The ROM code version is a 32-bit hexadecimal value at address 0x3BFFC.

### 27.4.2.2 RAM Memory Map

The partitioning of the on-chip SRAM (L3 OCM RAM) shown in [Figure 27-7](#) is used during the booting process. Tracing and static variables areas can also be accessed when calling API functions.

**Figure 27-7. RAM Memory Map**

- Downloaded image

This space is used by the public ROM code to store a downloaded booting image. It can be up to

48KB.

- Public stack  
This space is reserved for stack.
- RAM exception vectors

The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 27-12](#) lists the contents of the RAM space reserved for RAM vectors. The first eight addresses are ARM instructions that load the value in the subsequent eight addresses into the PC. These instructions are executed when an exception occurs because they are called from ROM exception vectors. Undefined, SWI, unused, and FIQ exceptions are redirected to a hardcoded dead loop. Prefetch abort, data abort, and IRQ exception are redirected to predefined ROM handlers. Users can redirect an exception to another handler by writing its address to the appropriate location from 0x4030 D024 to 0x4030 D03C, or by overriding the branch (load into PC) instruction between addresses from 0x4030 D004 to 0x4030 D01C.

**Table 27-12. RAM Exception Vectors**

Address	Exception	Content
0x4030 D000	Reserved	Reserved
0x4030 D004	Undefined	PC = [0x4030D024]
0x4030 D008	SWI	PC = [0x4030D028]
0x4030 D00C	Prefetch abort	PC = [0x4030D02C]
0x4030 D010	Data abort	PC = [0x4030D030]
0x4030 D014	Unused	PC = [0x4030D034]
0x4030 D018	Interrupt request (IRQ)	PC = [0x4030D038]
0x4030 D01C	Fast interrupt request (FIQ)	PC = [0x4030D03C]
0x4030 D020	Reserved	0x30090
0x4030 D024	Undefined	0x30080
0x4030 D028	SWI	0x30084
0x4030 D02C	Prefetch abort	Address of default prefetch abort handler <sup>(1)</sup>
0x4030 D030	Data abort	Address of default data abort handler <sup>(1)</sup>
0x4030 D034	Unused	0x30090
0x4030 D038	IRQ	Address of default IRQ handler
0x4030 D03C	FIQ	0x30098

<sup>(1)</sup> The default handlers for prefetch and data abort perform reads from CP15 debug registers to retrieve the reason for the abort:

- In case of prefetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM code jumps to the prefetch abort dead loop (20088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM code jumps to the data abort dead loop (2008Ch).

- Tracing data  
This area contains trace vectors reflecting the execution path of the ROM code. The public ROM code tracing data is described in [Table 27-13](#). For more information about ROM code tracing, see [Section 27.4.9, Tracing](#).

**Table 27-13. Tracing Data**

Address	Size (Bytes)	Description
0x4030 D040	4	Current tracing vector, word 1
0x4030 D044	4	Current tracing vector, word 2
0x4030 D048	4	Current tracing vector, word 3
0x4030 D04C	4	Cold reset run tracing vector, word 1
0x4030 D050	4	Cold reset run tracing vector, word 2
0x4030 D054	4	Cold reset run tracing vector, word 3

**Table 27-13. Tracing Data (continued)**

Address	Size (Bytes)	Description
0x4030 D058	4	Current copy of the PRM_RSTST register (reset reasons)
0x4030 D05C	4	Reserved
0x4030 D060	4	Reserved
0x4030 D064	4	Reserved

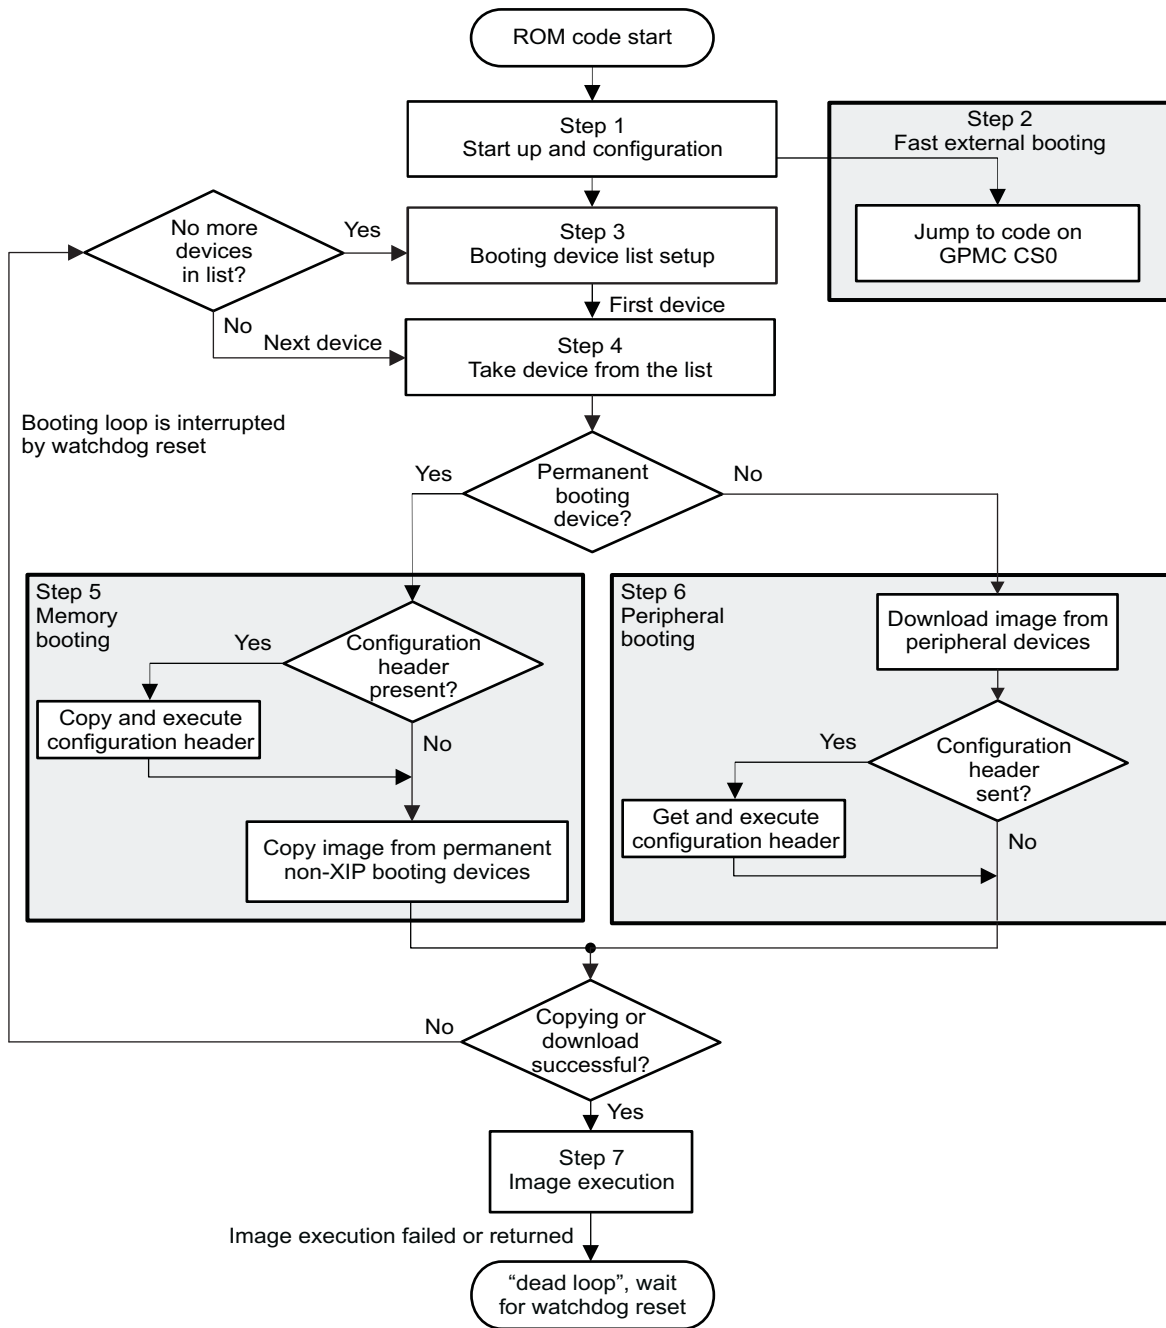

- Static variables

ROM code static variables used at boot time (and possibly during run time if calling the ROM API functions).

### 27.4.3 Overall Booting Sequence

[Figure 27-8](#) shows the ROM code flow chart.

Figure 27-8. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

- Step 1. Basic configuration and initialization. Reading of SYSBOOT pins or software booting configuration
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to an external addressable memory. See [Section 27.4.6, Fast External Booting](#).
- Step 3. A booting device list is created (see [Section 27.4.4.3, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the sys\_boot pins or the software booting configuration described in [Section 27.4.4.4, Software Booting Configuration](#). The software booting configuration structure is in the SAR memory and can be written by software before executing a software reset. After a software reset, the software booting configuration has priority over the sys\_boot pin configuration.
- Step 4. The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or when the watchdog expires. If an image is found, ROM code executes memory booting or peripheral booting, depending on the type of the current booting device:
  - Memory booting is executed when the booting device is XIP memory, NAND, OneNAND/Flex-OneNAND, or eMMC/eSD/MMC/SD.
  - Peripheral booting is executed when the device is a UART or USB.
- Step 5. Memory booting reads data from memory-type devices. Memory booting is described in detail in [Section 27.4.7, Memory Booting](#).
- Step 6. Peripheral booting downloads data from communication interfaces. Peripheral booting is described in [Section 27.4.5, Peripheral Booting](#).
- Step 7. For the GP device, the image is automatically started.

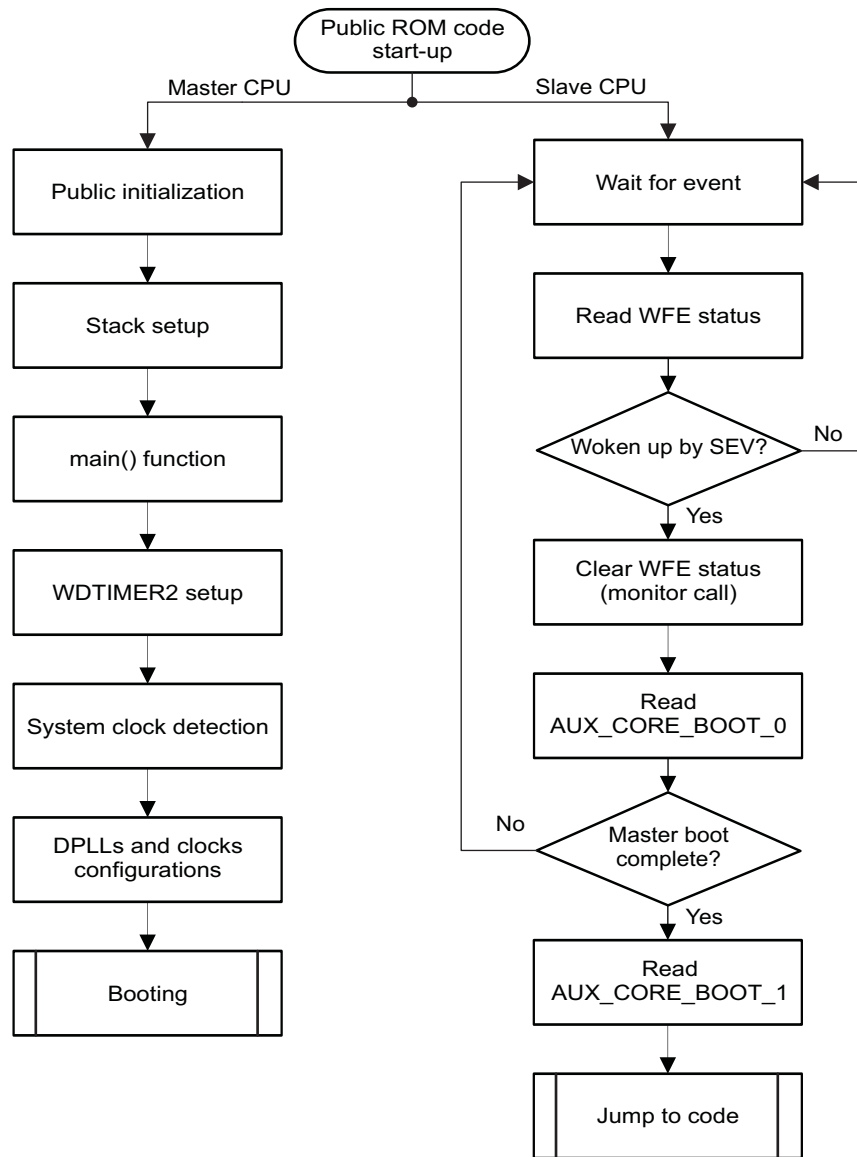

An additional feature of the booting module is the execution of the CH. The CH configures the system for faster and more flexible booting from the selected permanent device. The CH, which is optional, is described in [Section 27.4.8.2, Configuration Header](#).

## 27.4.4 Startup and Configuration

### 27.4.4.1 Startup

[Figure 27-9](#) shows the ROM code start-up sequence.

Figure 27-9. ROM Code Multiprocessor Start-Up Sequence

init-042

The master CPU L1 instruction cache and branch prediction mechanisms are activated as part of the public boot process. The public vector base address is configured to the reset vector of ROM code (0x30000). The memory management unit (MMU) remains switched off during boot (thus, L1 data cache is off). The master CPU performs the public-side basic initialization and stack setup (compiler auto-generated C- initialization or *scatter loading*). Next, it configures WDTIMER2 (set to 3 minutes), performs system clock detection, and configures the system clock. Finally, it jumps to the booting routine.

No specific configuration is performed for the slave CPU, which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of public-vector-base address). The slave CPU is rapidly held in wait-for-event state. It stays in this state while the master CPU completes the public boot process and until jumping to the external software (for example, HLOS). At this stage, the external software can wake up the slave CPU by executing an SEV command.

Two internal memory-mapped registers are available to the OS for communicating start-up information. The AUX\_CORE\_BOOT\_0 and AUX\_CORE\_BOOT\_1 registers are in the MPU WakeupGen domain.

- AUX\_CORE\_BOOT\_0 is used as a status register to signal the slave CPU that it must wake up after the send event operation initiated by the master CPU.

- AUX\_CORE\_BOOT\_1 contains the address location to which the slave CPU must jump after wakeup. See the memory mapping of these registers in [Chapter 4, Dual Cortex-A9 Subsystem](#).

#### 27.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL: Set to provide 192, 128, 96, 48, 24, and 12 MHz for peripheral blocks
- Core DPLL: Set to provide L3/L4 interconnect and MPU and EMIF clocks
- MPU DPLL: Left in bypass, and the MPU internal clock is derived from the core DPLL
- USB DPLL: Locked only in case of USB peripheral booting from internal transceiver. It is left unused in other cases (for example, memory boot or peripheral boot from UART or USB ULPI) to save power.

The multipliers and dividers of the DPLLs are set to values that depend on the input clock detected.

[Table 27-14](#) summarizes the ROM code default settings for key clocks.

**Table 27-14. ROM Code Default Clock Settings**

Clock	Frequency [MHz]	Source
<b>FCORE_DPLL</b>	400	Derived from SYS_CLK
CORE_X2_CLK	200	
CORE_CLK	200	CORE_X2_CLK/1
L3_ICLK	100	CORE_CLK/2
L4_ICLK	50	L3_ICLK/2
<b>FPER_DPLL</b>	384	Derived from SYS_CLK
FUNC_192M_CLK	192	
FUNC_128M_CLK	128	
FUNC_96M_FCLK	96	
FUNC_48M_FCLK	48	
<b>FMPU_DPLL</b> (in bypass)	200	CORE_X2_CLK
MPU_DPLL_CLK	200	FMPU_DPLL/1
<b>FUSB_DPLL</b> <sup>(1)</sup>	960	Derived from SYS_CLK
INIT_960M	960	FUSB_DPLL/1
INIT_480M	480	FUSB_DPLL/2
INIT_60M	60	INIT_480M/8

<sup>(1)</sup> Locked only in case of USB peripheral booting from internal PHY

There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in [Table 27-14](#). They are always applied at any reset.
- Software booting configuration after a software reset, described in [Section 27.4.4.4, Software Booting Configuration](#)
- The CH, described in [Section 27.4.8.2, Configuration Header](#). The CH lets users have a known configuration (about GPMC and clock registers) after memory booting. This configuration can be blocked by the software booting configuration.

### 27.4.4.3 Booting Device List Setup

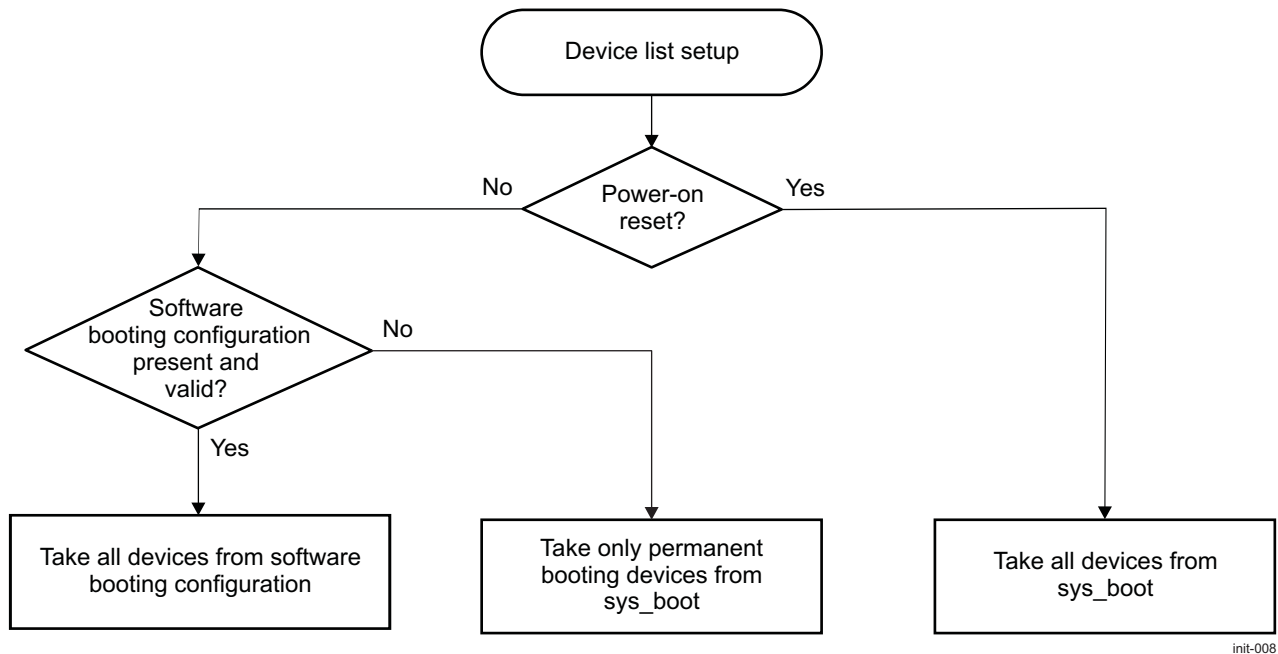

The ROM code creates a device list based on two sources:

- The software booting configuration is stored in nonvolatile RAM SAR memory.
- The sys\_boot[5:0] pins sensed in the control module are used to index the device table from which the list of devices is extracted.

Figure 27-10 shows how the ROM code sets up the device list depending on the reset source.

**NOTE:** Only permanent booting devices are put on the list when reset is not power on and devices are taken from the sys\_boot pins. Users can force peripheral booting after software reset using the software booting configuration.

Figure 27-10. Device List Setup

init-008

### 27.4.4.4 Software Booting Configuration

The software booting configuration is a logical structure stored in SAR RAM memory, which is not cleared after warm resets or wakeups from low-power modes.

#### 27.4.4.4.1 Public Use of SAR RAM

At system level, the OMAP4460 SAR RAM memory is divided into four banks. The public ROM code uses only the first bank, which is always public-accessible. More specifically, the software booting configuration structure must be in the upper 1.5KB of the first bank.

The public ROM code offers some flexibility about the location of the software booting configuration structure. The PUBLIC\_SW\_BOOT\_CFG\_ADDR pointer defines the start address of the structure within the SAR RAM bank (see Table 27-15).

Table 27-15. Public Use of SAR RAM

Logical name	Address	Size (Bytes)	Description
PUBLIC_SW_BOOT_CFG_ADDR	0x4A32 6A00	4	Public software booting configuration pointer. The word value at this location is: - Reset (zero) on a cold reset. - Read on a warm reset.

**Table 27-15. Public Use of SAR RAM (continued)**

Logical name	Address	Size (Bytes)	Description
CPU0_WAKEUP_NS_PA_ADDR	0x4A32 6A04	4	CPU0 nonsecure wake-up restoration pointer <sup>(1)</sup>
CPU1_WAKEUP_NS_PA_ADDR	0x4A32 6A08	4	CPU1 nonsecure wake-up restoration pointer <sup>(1)</sup>
PUBLIC_SAR_RAM_1_FREE	0x4A32 6A0C	...	Recommended address for start of software booting configuration structure described in <a href="#">Section 27.4.4.4.2, Software Booting Configuration Structure</a> .

<sup>(1)</sup> This pointer is used as part of the restoration procedure from low-power modes.

As mentioned previously, the software booting configuration feature is optional. Hence, the public ROM code decides to use the feature based on the value read on a warm reset at the address pointed to by the PUBLIC\_SW\_BOOT\_CFG\_ADDR pointer. If the value matches the range 0x4A32 6A00–0x4A32 6FFF, the ROM code tries to extract the structure at that address. The value pointed to by PUBLIC\_SW\_BOOT\_CFG\_ADDR is always overwritten to 0 on a cold reset.

The recommended address for storing the software booting configuration structure described hereafter is defined as PUBLIC\_SAR\_RAM\_1\_FREE. It is, however, possible to locate the structure at any location within the 1.5-KB range.

It is moreover possible to use the public SAR RAM area for any other purpose, such as storing traces for HLOS use. Obviously, care must be taken not to overwrite the locations used for low-power modes and/or software booting configuration if used.

#### 27.4.4.4.2 Software Booting Configuration Structure

[Table 27-16](#) describes the software booting configuration structure. It offers three levels of flexibility for redefining the ROM code defaults after a warm reset:

- Redefining the default device booting list (from ROM code defaults given by SYSBOOT pins configuration)
- Redefining the default clock settings
- Redefining time-outs linked to the peripheral booting mechanism

---

**NOTE:** The sections are provided as a linked list; therefore, the order and number of items is not relevant.

---

The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration overwrites the CH settings.

Padding	2	

## 27.4.5 Peripheral Booting

### 27.4.5.1 Description

The ROM code can boot from two different peripherals:

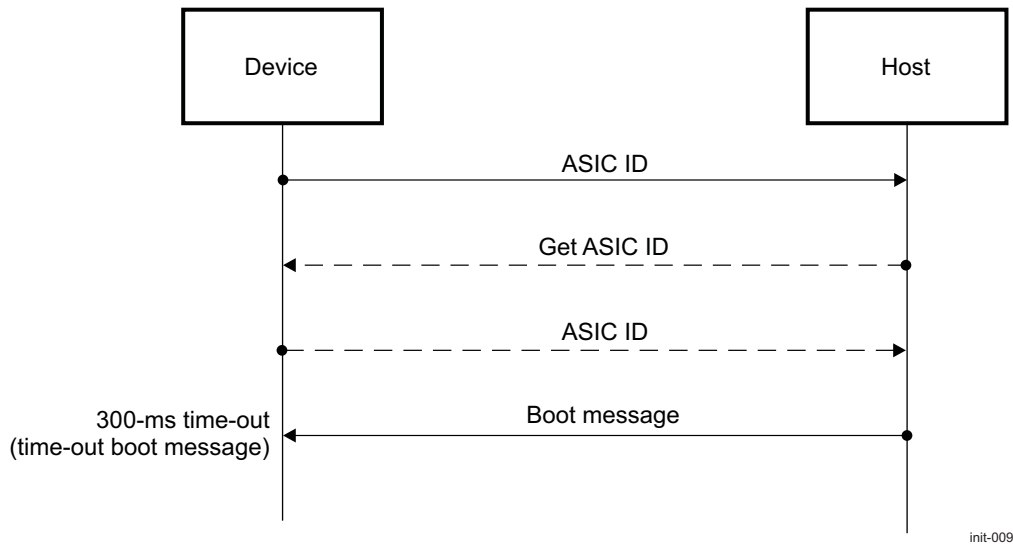

- USB: High-/full-speed USB from internal or external transceiver

- UART3: 115.2 Kbps, 8 bits, even parity, 1 stop-bit

The purpose of booting from a peripheral is to download a flash loader code from an external host. This booting method is used primarily for programming flash memories connected to the OMAP device (for example, in the case of initial flashing, firmware update or servicing). The overall peripheral booting procedure is shown in [Figure 27-13](#). It consists of a synchronization phase (handshake between host and OMAP device) and a transfer phase. The synchronization phase is similar for UART and USB boots. Both transfer phases use the same procedure.

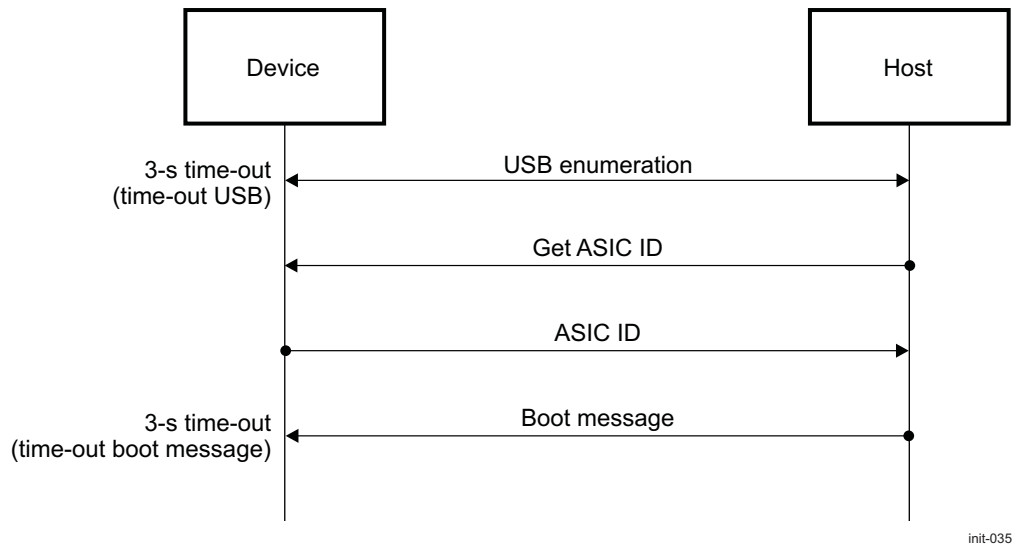

When booting from the UART, the ROM code first initializes the UART3 interface. Then the ROM code sends an ASIC ID block of data. From there, it expects to receive a boot message from the host within 300 ms, by default. [Figure 27-11](#) shows this procedure.

**Figure 27-11. Synchronization Phase for UART**

[Figure 27-12](#) shows the procedure when booting from the USB.

**Figure 27-12. Synchronization Phase for USB**

During the synchronization phase (see [Figure 27-11](#) and [Figure 27-12](#)), the OMAP device can provide a small packet of data called the ASIC ID (described in [Table 27-17](#)). It is a simple structure that contains different kinds of information, such as ROM version, checksums, and ID.

The default time-outs involved during the synchronization phase can be redefined after a warm reset by means of the software booting configuration (described in [Section 27.4.4.4, Software Booting Configuration](#)). The host can decide the desired operation by providing a booting message (see [Table 27-21](#)). This message can be: Get ASIC ID, peripheral boot, change device, or next device. If the OMAP device receives the Get ASIC ID boot message, it sends back the ASIC ID contents.

If the change device or next device message is received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which decides about the next booting device according to the boot message received.

If the peripheral boot message is received without a time-out, the OMAP device is entering the transfer phase. From there, the flash loader image size (as a 32-bit word) and the flash loader image itself are expected to be received. The ROM code waits up to 1 minute for completion of image size reception, and up to 1 more minute to download the image. If the download procedure does not complete before this time, the peripheral booting returns with a TIMEOUT status. ROM code continues to examine the devices included in the booting device list. If the download procedure passes, the peripheral booting returns with a SUCCESS status and the image can be executed.

The USB or UART connection is left open at the end of the transfer phase and once exiting the ROM code for the initial software to take over. It means the initial software can reuse the currently established connection. In the case of a USB connection, the endpoints can be reused as such, without closing the connection and performing a full enumeration again.

**Table 27-17. ASIC ID Structure**

ASIC ID Item	Size (Bytes)	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved subblock	4	This subblock is transmitted, but does not contain useful information in case of GP device.
Reserved subblock	23	This subblock is transmitted, but does not contain useful information in case of GP device.
Reserved subblock	35	This subblock is transmitted, but does not contain useful information in case of GP device.
Checksum subblock	11	CRC (4 bytes)

**Table 27-18. Items**

Offset	Size (Bytes)	Description
0x00	1	0x05: Number of subblocks USB 0x04: Number of subblocks UART <sup>(1)</sup>

<sup>(1)</sup> The checksum subblock is not transmitted over the UART.

**Table 27-19. ID Subblock**

Offset	Size (Bytes)	Description
0x01	1	0x01: Subblock ID
0x02	1	0x05: Subblock size
0x03	1	0x01: Fixed value
0x04	2	0x44, 0x40: OMAP4460 device
0x06	1	0x07: CH enabled (read from eFuse) 0x17: CH disabled (read from eFuse)
0x07	1	ROM revision

**Table 27-20. Checksum Subblock<sup>(1)</sup>**

Offset	Size (Bytes)	Description
0x47	1	0x09: Subblock size
0x48	1	0x01: Fixed value
0x49	4	ROM CRC
0x4D	4	0x00000000: For GP device

**Table 27-21. Booting Messages**

Message Name	Value	Description
Peripheral boot	0xF003 0002	Continue peripheral booting.
Get ASIC ID	0xF003 0003	ASIC ID request. The Get ASIC ID request message is optional. If received, the ROM code sends its ASIC ID data to the host in return. The host can issue the Get ASIC ID message multiple times if required. The structure of the ASIC ID is described in <a href="#">Table 27-17</a> .
Change device	0xF003 xx06	Skip current peripheral booting and continue booting from device type indicated by xx: 0x00: Void, no device 0x01: XIP memory 0x02: XIPWAIT memory (wait-signal monitoring on) 0x03: NAND 0x04: OneNAND 0x05: MMC1 0x06: MMC2(1) 0x07: MMC2(2) 0x43: UART 3 0x45: USB(1) (internal transceiver) 0x46: USB-ULPI 0x47: USB(2) (internal transceiver) Others: Reserved
Next device	0xFFFF FFFF	Skip current device and move to the next device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first device for memory booting.

Figure 27-13 shows the peripheral booting procedure.

**Figure 27-13. Peripheral Booting Procedure**

init-010

### 27.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX
- The boot message default time-out is 300 ms (time-out boot message)

### 27.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HSUSBOTG interface (USBA0)
- OMAP integrated transceiver (USBPHY) or external transceiver through the ULPI
- Enumeration default time-out is 3 s (time-out USB)
- The boot message default time-out is 3 s (time-out boot message).

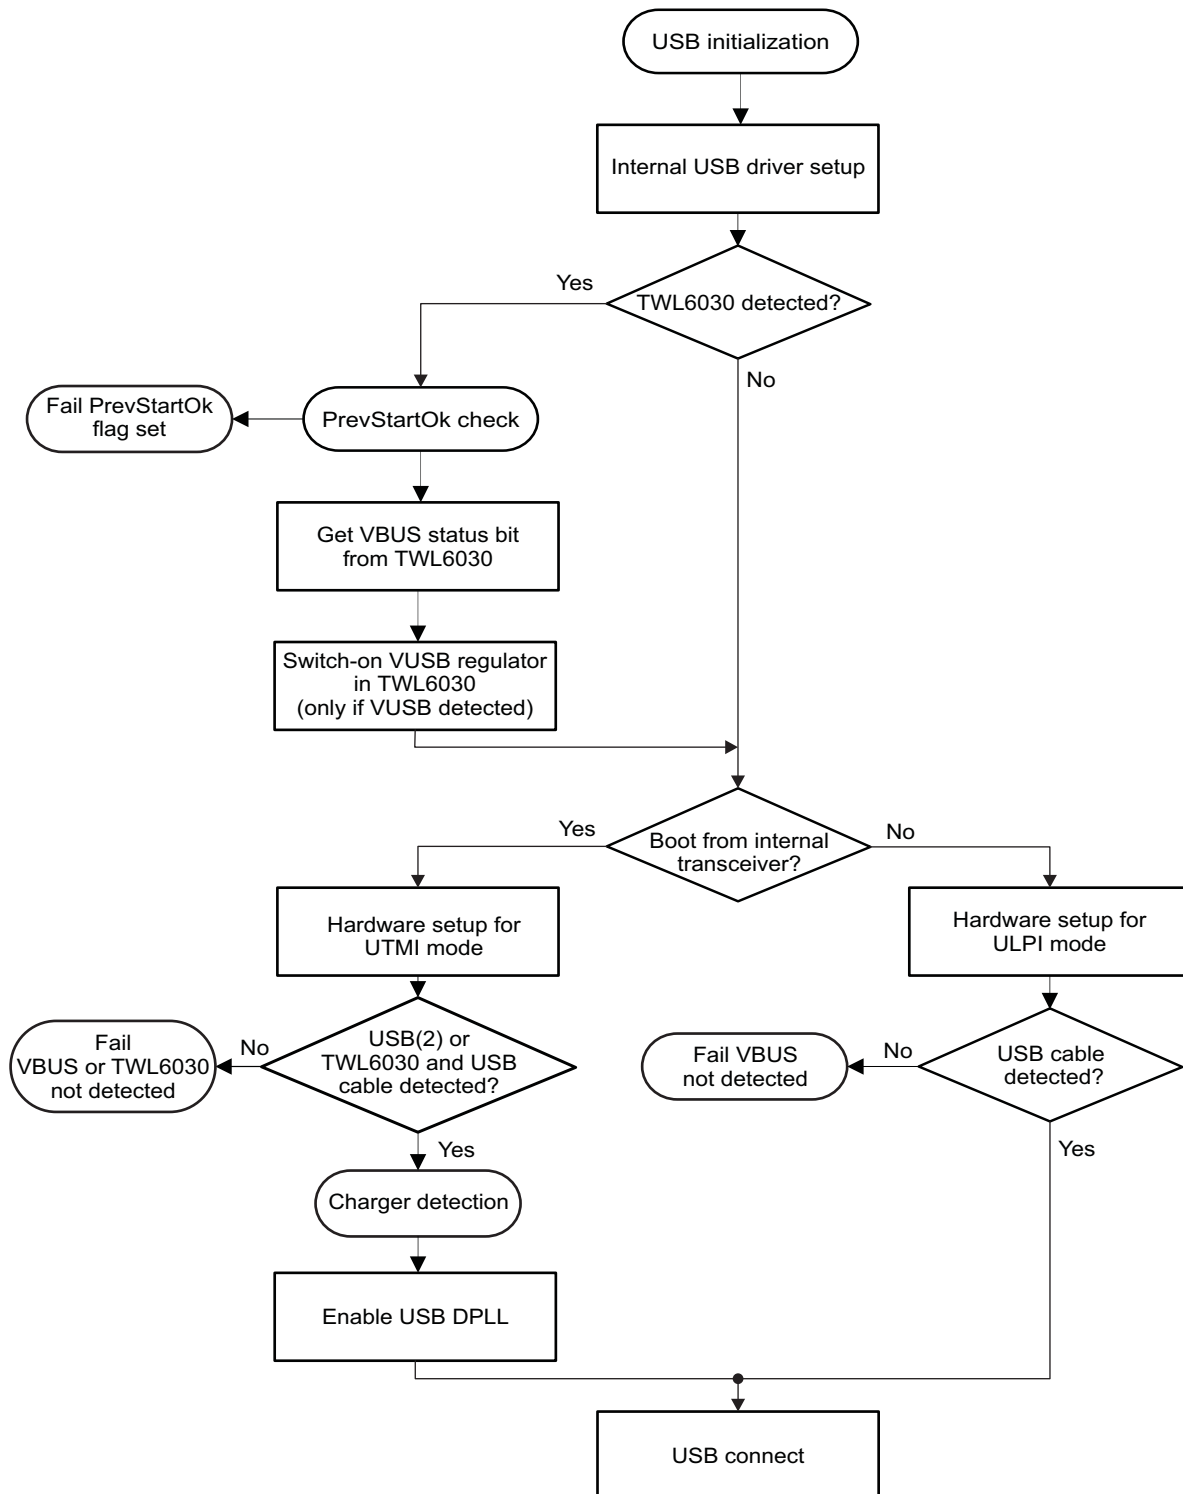

---

**NOTE:** Even though using OTG-capable hardware, the ROM code does not handle any OTG-specific features.

---

#### 27.4.5.3.1 Overview

[Figure 27-14](#) shows the USB initialization procedure.

**Figure 27-14. USB Initialization Procedure**

init-037

After internal USB module driver setup, the TWL6030 power IC is checked for presence. If found, the following actions are performed using I<sup>2</sup>C transactions through the I2C1 interface:

- PrevStartOk status flag check, as described in [Section 27.4.5.3.2](#).
- Get the VBUS status reflecting presence (or not) of the USB cable

- If VBUS was detected, then the VUSB regulator is enabled to power the internal OMAP transceiver.

In case of boot from external transceiver in accordance with the chosen SYSBOOT configuration:

- The HSUSBOTG hardware and PRCM clocks are configured for ULPI mode.
- The ROM code continues with the USB procedure only if the USB cable is detected (that is, VBUS is detected at external transceiver level and communicated as such through the ULPI traffic). If not, the initialization procedure is aborted.

---

**NOTE:** The OMAP USB DPLL is not set up in case of ULPI mode, for which the 60-MHz clock is driven by the external transceiver.

---

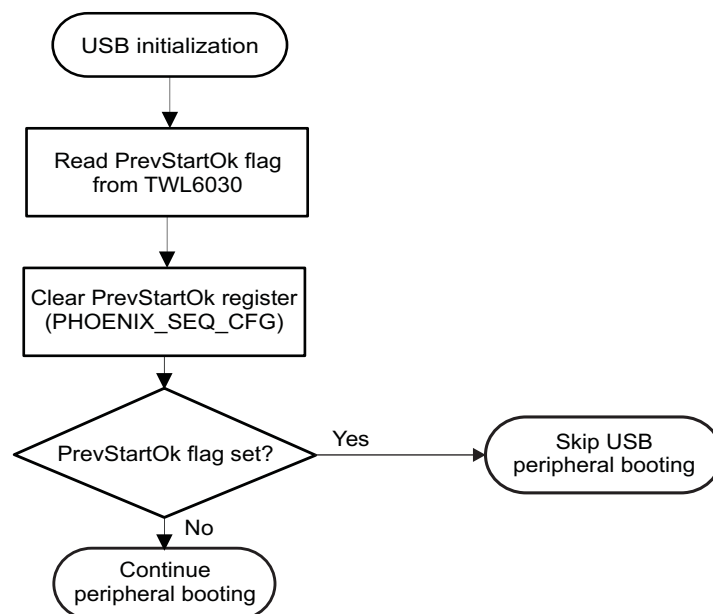

In case of boot from internal transceiver in accordance with the chosen SYSBOOT configuration:

- The USBOTGHS hardware and PRCM clocks are configured for UTMI mode and internal PHY clocks are enabled.
- For USB(1) only: The ROM code continues with the USB procedure only if the TWL6030 is detected and the USB cable is detected as present (that is, VBUS is detected at the TWL6030 level and read as such with a register read through I2C interface). If not, the initialization procedure is aborted.
- For USB(2) only: The ROM code continues with the USB procedure even if the TWL6030 is not detected and the USB cable is not detected as present at the TWL6030 level. This enables a USB boot with internal transceiver even without the TWL6030.
- The ROM code proceeds with charger detection, as described in [Section 27.4.5.3.2](#).
- It enables the USB DPLL for feeding the appropriate 60-MHz clock needed by the internal transceiver.

### 27.4.5.3.2 PrevStartOk Status Flag Check

The ROM code supports a mechanism for avoiding the boot time spent because of the enumeration time-out (default 3 s) in case the USB cable is attached and the USB option is present in the selected boot list but is not intended to initiate a peripheral booting procedure (for example, firmware update or flashing). This mechanism is jointly handled with the support of the TWL6030 device (not supported if TWL6030 is not detected). This mechanism is supported only for USB and not UART (see [Figure 27-15](#)).

**Figure 27-15. PrevStartOk Mechanism**

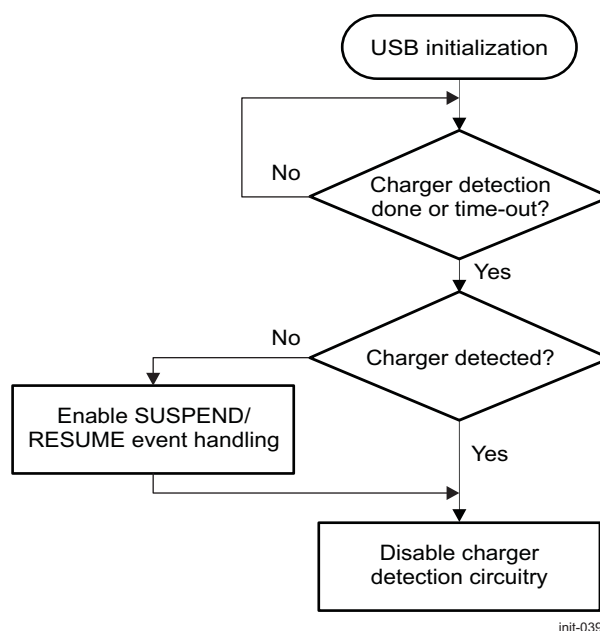

init-038

The ROM code first checks the value of a register in the TWL6030 RTC domain (hence, retained by the backup battery when the platform is switched off) by an I<sup>2</sup>C read access. If the PrevStartOk bit in this register is set, the USB peripheral booting is simply skipped. In any case, the bit is reset (zeroed) by the ROM code, which means that the USB peripheral boot is re-enabled on the next cold reset (or warm reset if suitable software booting configuration is present). The initial software of the user must reset this bit by an I<sup>2</sup>C write access to disable USB peripheral booting on a subsequent reset. For more information about the accesses made toward the PrevStartOk bit in the PHOENIX\_SEQ\_CFG register, see TWL6030 documentation.

### 27.4.5.3.3 Charger Detection

The ROM code proceeds with charger detection as part of the USB peripheral booting procedure and in compliance with *Battery Charging Specification Revision 1.1*. It uses the specific charger detection hardware embedded in the OMAP device. [Figure 27-16](#) shows the high-level procedure.

**Figure 27-16. Charger Detection**

The hardware charger detection mechanism should end up within the 500-ms time-out. The main goal of such detection is to gate the charger circuitry in TWL6030 in case a charger is not detected and a suspend event is detected on the OMAP side, for which the power consumption must be reduced.

### 27.4.5.3.4 SUSPEND and RESUME Handling

The SUSPEND event is detected by the HSUSBOTG module when activity on the bus stops for at least 3 ms. During peripheral booting time, a SUSPEND event is detected by the ROM code and processed by initiating a write into the TWL6030 to gate the charging circuitry. The ROM code releases the TWL6030 charger circuitry upon getting a RESUME event. During run time, SUSPEND and RESUME interrupts can be routed to the initial software to define custom handling.

### 27.4.5.3.5 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable description information. These descriptor details can be used for tool development or debugging:

- Device descriptor

A device descriptor contains general information about a USB device, including global information that applies to the device and all device configurations. A USB device has only one device descriptor. A device-qualifier descriptor is required because the ROM code uses the HS feature of the USB core. [Table 27-22](#) lists the device descriptors.

**Table 27-22. Device Descriptor**

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID (Texas Instruments), TI default value
idProduct	0xD010	Product ID (OMAP4460), TI default value
bcdDevice	0x0000	Device release number
iManufacturer	See <a href="#">Section 27.4.5.3.6</a> .	Index of string descriptor describing manufacturer
iProduct	See <a href="#">Section 27.4.5.3.6</a> .	Index of string descriptor describing product
iSerialNumber	See <a href="#">Section 27.4.5.3.6</a> .	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the `GetDescriptor()` request (standard device request). [Table 27-23](#) describes a device-qualifier descriptor.

**Table 27-23. Device-Qualifier Descriptor**

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- Configuration descriptor

This descriptor gives information about a specific device configuration. It describes the number of interfaces supported by the configuration (see [Table 27-24](#)).

**Table 27-24. Configuration Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the <code>SetConfiguration()</code> request
iConfiguration	Index	Index of string descriptor describing this configuration

**Table 27-24. Configuration Descriptor (continued)**

Field	Value	Description
bmAttributes	0xC0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Other speed configuration descriptor  
This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed (see [Table 27-25](#)).

**Table 27-25. Other Speed Configuration Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type
wTotalLength	–	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xC0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor  
This descriptor describes a specific interface in a configuration (see [Table 27-26](#)).

**Table 27-26. Interface Descriptor**

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor  
Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request (see [Table 27-27](#) and [Table 27-28](#)).

**Table 27-27. BULK IN Endpoint Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See <sup>(1)</sup> .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

<sup>(1)</sup> The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

**Table 27-28. BULK OUT Endpoint Descriptor**

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See <sup>(1)</sup> .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

<sup>(1)</sup> The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

For the description of the different string descriptors, see:

- The language ID string descriptor ([Table 27-29](#))
- The manufacturer ID string descriptor ([Table 27-30](#))
- The product ID string descriptor ([Table 27-31](#))
- The configuration string descriptor ([Table 27-32](#))
- The interface string descriptor ([Table 27-33](#))

**Table 27-29. Language ID String Descriptor**

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type

### 27.4.5.3.6 USB Customized Descriptors

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on the VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done.

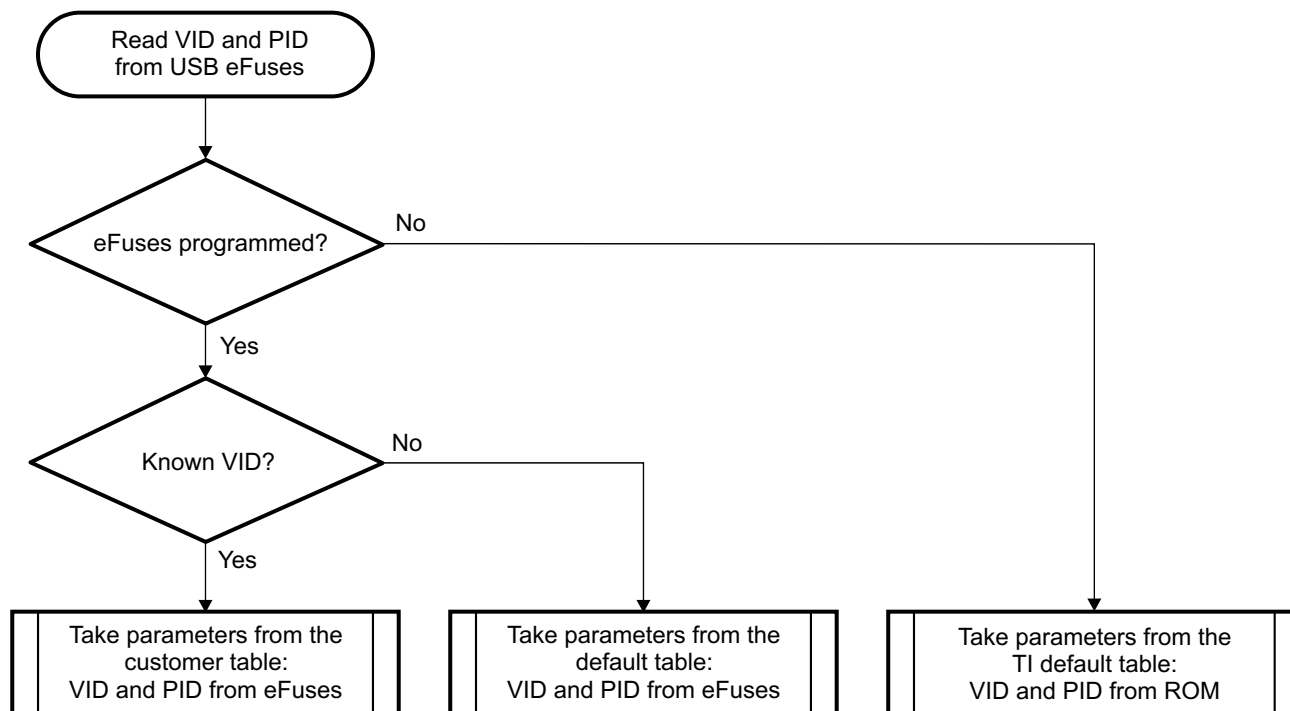

[Table 27-34](#) lists the parameters that depend on the VID value.

**Table 27-34. Customized Descriptor Parameters**

Parameter	Size (Bytes)	Default Values (From eFuses)	TI Default Values (From ROM)
Device ID code	2	0x0000	0x0000
Device class	1	0xFF	0xFF
Device subclass	1	0xFF	0xFF
Device protocol	1	0xFF	0xFF
Manufacturer	String	N/A	Texas Instruments
Product	String	OMAP4440	OMAP4440
Serial number	String	See <sup>(1)</sup> .	See <sup>(1)</sup> .

<sup>(1)</sup> The standard device descriptor indicates that the device has no serial number.

[Figure 27-17](#) shows an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

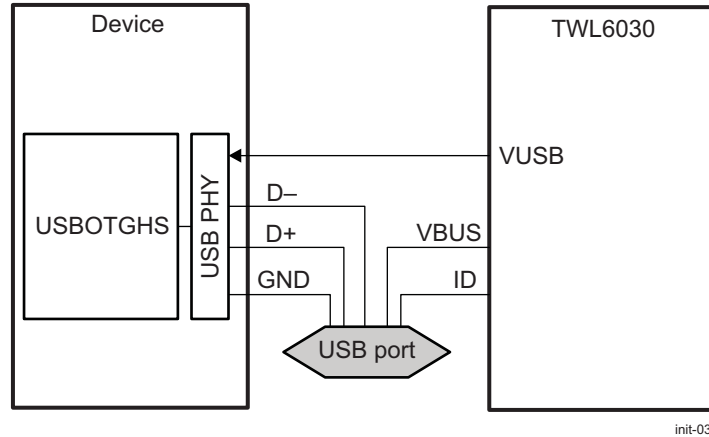

**Figure 27-17. Customer USB Descriptor Selection**

init-011

**27.4.5.3.7 System Interconnection – Integrated Transceiver**

When SYSBOOT selects the embedded PHY, the USB power/data path can be described as shown in Figure 27-18.

**Figure 27-18. USB System Using Internal Transceiver**

init-036

**NOTE:** USB(2) booting mode allows an alternate power-management IC to be used. In that case, the internal transceiver must be powered and configured upon startup and does not require any action from the ROM code for its configuration.

**27.4.5.3.8 System Interconnection – External Transceiver**

The USBOTGHS module uses the ultralow-pin-count interface (ULPI) to interconnect with an external USB transceiver. In this case, the ROM code does not interact with the transceiver. Thus, users must ensure that the transceiver power supply and clock are present and the transceiver is out of reset.

**27.4.5.3.9 USB Driver Functionality**

- Transactions supported:
  - Control transactions: Used for standard device requests
  - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent to the BULK IN endpoint and the image is transferred from the host over the BULK OUT endpoint.

The OMAP USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are answered with the corresponding descriptors.
- Standard device request restrictions:
 

Some standard device requests are not supported by the driver because the USB driver is dedicated for use by the ROM code for peripheral booting. Table 27-35 lists the standard device requests supported by the driver.

**Table 27-35. Standard Device Requests Supported**

Request	Description	Support
CLEAR_FEATURE	Sets/clears a specific feature	Supported only for ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes

**Table 27-35. Standard Device Requests Supported (continued)**

Request	Description	Support
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for ENDPOINT_HALT feature
SET_INTERFACE	Selects an alternate setting in an interface	Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

## 27.4.6 Fast External Booting

### 27.4.6.1 Overview

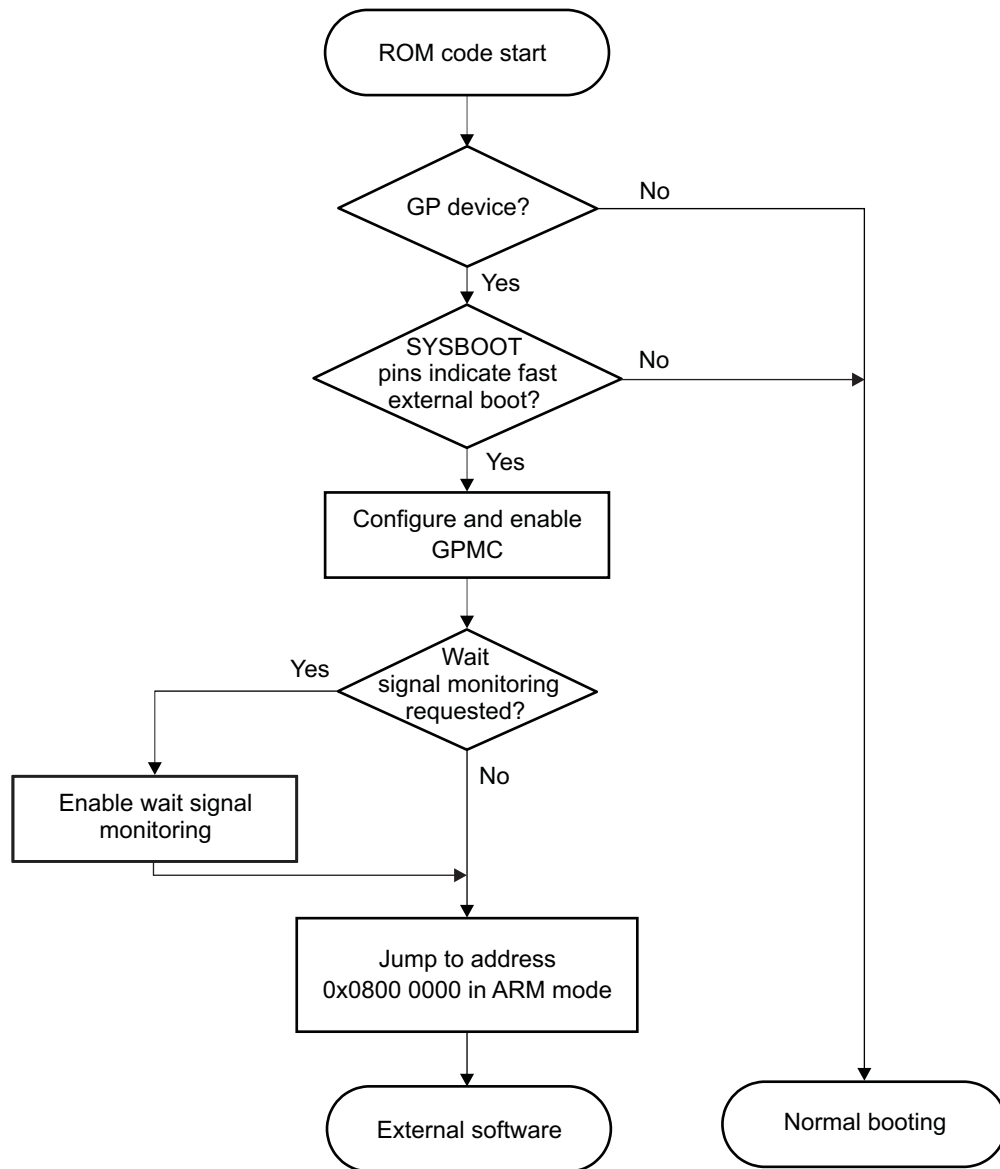

The fast external boot is a special memory booting mode, possible only on GP devices. It consists of a blind jump to a code in an external XIP memory device connected to GPMC CS0. Fast external booting is set up by means of the SYSBOOT configuration pins and lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

### 27.4.6.2 Fast External Booting Procedure

[Figure 27-19](#) shows the fast external boot procedure. The code is at the beginning and is written in Assembly Language. The code does not use any RAM and is designed for fast execution.

Figure 27-19. Fast External Boot Procedure

init-013

## 27.4.7 Memory Booting

### 27.4.7.1 Overview

The memory booting process starts an external code in memory devices. Only memory type of booting devices can be used by ROM code as permanent booting devices (that is, devices examined after both cold (POR) and warm resets). Temporary booting devices are examined only after cold resets. The supported permanent booting devices are:

- NOR flash devices
- NAND flash devices
- OneNAND/Flex-OneNAND devices
- eMMC/eSD embedded flash memories
- SD/MMC flash cards

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

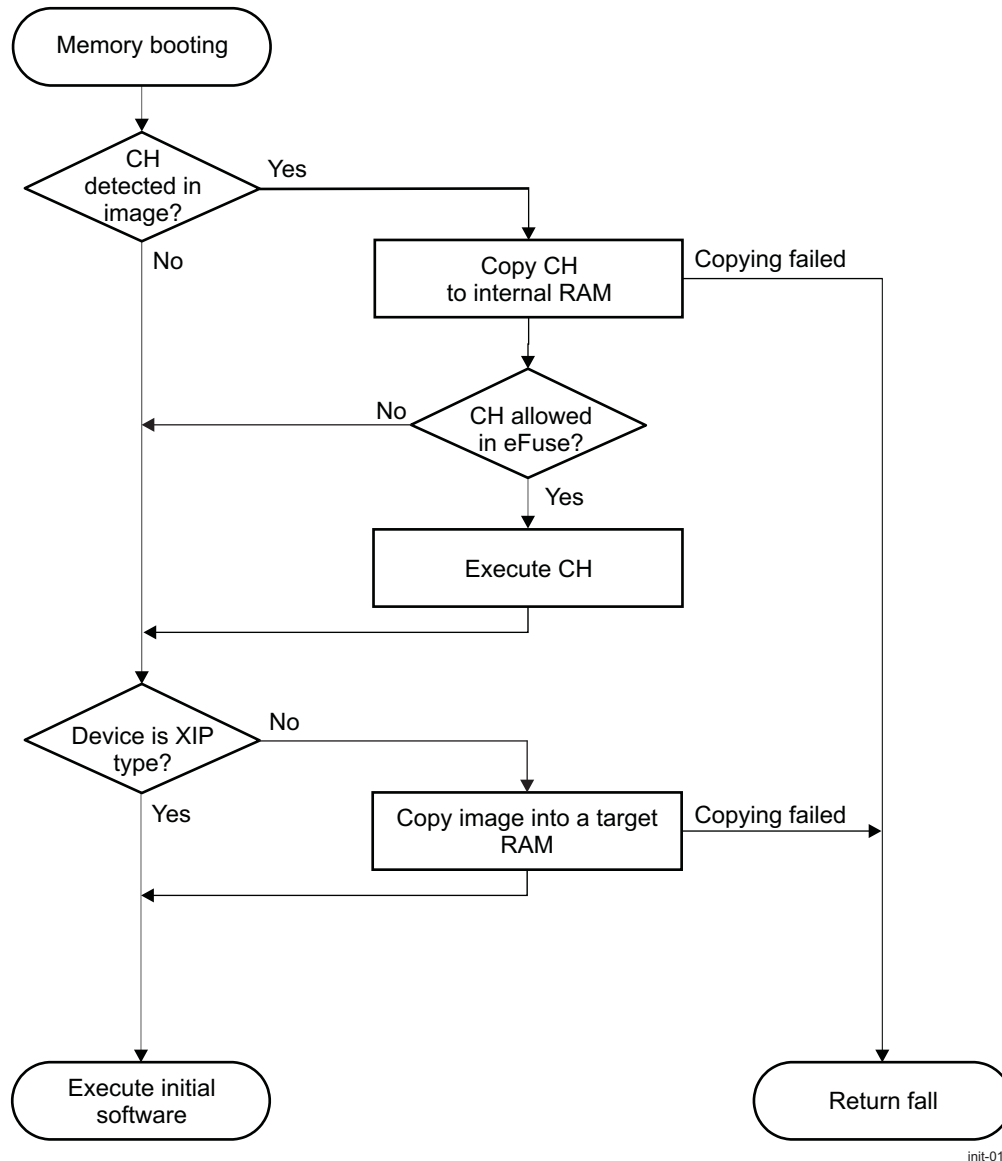

[Figure 27-20](#) shows the general memory booting procedure common to all types of devices. First, CH is copied to internal RAM. It is copied even for XIP devices, because the OMAP device can temporarily lose a connection with XIP memory during CH execution. The second step is to shadow the image, if the device is not XIP. The last step is image execution and any return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

During the first read sector (512 bytes) call, sectors are copied to a temporary RAM buffer. Once the image is found and the destination address is known, the content of the temporary buffer is moved to the target RAM location so it is required to reread the first image sector. On a GP device, the GP header is discarded; therefore, only executable code is in RAM, with the first executable instruction at the destination address.

eMMC/eSD embedded memories, MMC/SD cards, NAND, and OneNAND/Flex-OneNAND devices can hold up to four copies of the booting image. Therefore, the ROM code searches for one valid image out of the four, if present, by walking over the first blocks of mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

Figure 27-20. Memory Booting Procedure

### 27.4.7.2 Non-XIP Memory

Figure 27-21 shows the procedure used when memory booting runs with non-XIP devices. The shaded procedures are specific to each device. NAND and OneNAND/Flex-OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

**Figure 27-21. Image Shadowing on GP Device**

[Table 27-36](#) summarizes the number of blocks and sectors searched during memory booting from devices requiring image shadowing. A sector is assumed to be 512 bytes long. NANDs and OneNAND/Flex-OneNAND are organized with blocks, which are erasable units. MMC/SD/eMMC/eSD + FAT12/16/32 booting consists of reading a file.

**Table 27-36. Blocks and Sectors Searched on Non-XIP Memories**

Memory	Maximum Number of Checked Blocks	Number of Sectors Searched
NAND	First 4	Number of sectors in a block <sup>(1)</sup>
OneNAND/Flex-OneNAND	First 4	8
eMMC/eSD raw	First 4	1
MMC/SD raw	First 4	1
MMC/SD/eMMC/eSD + FAT12/16/32	1 File	

<sup>(1)</sup> Depends on NAND geometry

For more information about the GPMC module, see [Section 15.4, GPMC Overview](#).

The following sections describe the supported device types.

### 27.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1 Gb (128MB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 50 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc\_wait0 is monitored according to the sys\_boot configuration pins.

Depending on the SYSBOOT option, the GPMC can be configured to use the wait signal connected to the gpmc\_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc\_wait0 is low. Wait-signal monitoring is used with memories that require a long time for initialization after reset, or that must pause while reading data.

For an XIP memory booting, no user intervention is required; the following debugging steps are described. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

Bootting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.
2. Verify that the CH is present at address 0x0800 0000. If it is, copy the entire sector (512 bytes) to internal RAM and execute the CH.
3. Set the image location:
  - 0x0800 0000 if the CH is not found
  - 0x0800 0200 if the CH is found
4. Verify that a bootable image is at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

#### 27.4.7.3.1 GPMC Initialization

[Table 27-37](#) lists the timing settings of the GPMC when set for XIP and other address-data accessible devices, such as OneNAND/Flex-OneNAND. [Table 27-37](#) is included for debug information.

**Table 27-37. XIP Timing Parameters**

Parameter	Value [Clock Cycles] (1)	Register Initialization (where i = 0–7)	Reset Value
Write cycle period	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.	0x11
Read cycle period	17	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11.	0x11
CS low time	1	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1.	0x1
CS high time	16	The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10.	0x10
ADV low time	1	The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1.	0x1
ADV high time	2	The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2.	0x2
OE low time	3	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3.	0x6
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x05

(1) The one clock cycle is 20 ns, which corresponds to 50-MHz frequency.

**Table 27-37. XIP Timing Parameters (continued)**

Parameter	Value [Clock Cycles] (1)	Register Initialization (where i = 0–7)	Reset Value
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	15	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF.	0x0F

There is no specific identification routine executed before booting from an XIP device.

#### 27.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 512 Mbit (64MB)
- x8 and x16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128/218 spare bytes)
- Chip enable (CE) don't care devices only
- Single-level cell (SLC) and multilevel cell (MLC) devices
- Device identification based on ONFI or ROM table
- ECC correction: 8 bits/sector for most devices (16 bits/sector for devices with large spare area)
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 50 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc\_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for an image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

##### 27.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection.

- GPMC initialization

The GPMC interface is configured so that it can access NAND. Because NAND memories do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. [Table 27-38](#) shows the GPMC configuration used during NAND boot. [Table 27-38](#) is included for debug information.

**Table 27-38. NAND Timing Parameters**

Parameter	Value (Clock Cycles)	Register Initialization (where i = 0–7)	Reset Value
Write cycle time	20	GPMC_CONFIG5_i[12:8] WRCYCLETIME = 0x14	0x11
Read cycle time	20	GPMC_CONFIG5_i[4:0] RDCYCLETIME = 0x14	0x11
CS low time	0	GPMC_CONFIG2_i[3:0] CSONTIME = 0x0	0x1
CS low to OE low time	5	GPMC_CONFIG4_i[3:0] OEONTIME = 0x5	0x6
CS low to OE high time	16	GPMC_CONFIG4_i[12:8] OEOFFTIME = 0x10	0x10

**Table 27-38. NAND Timing Parameters (continued)**

Parameter	Value (Clock Cycles)	Register Initialization (where i = 0–7)	Reset Value
CS low to WE low time	1	GPMC_CONFIG4_i[19:16] WEONTIME = 0x1	0x5
CS low to WE high time	15	GPMC_CONFIG4_i[28:24] WEOFFTIME = 0xF	0x10
CS low to data latch time	14	GPMC_CONFIG5_i[20:16] RDACCESSTIME = 0xE	0xF

- Device detection and parameters

The ROM code first performs an initial wait for device auto initialization (with 250-ms time-out) with polling of the ready information. Then, it must identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 100-ms time-out). The ONFI Read ID (command 90h/address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent. The information provided in [Table 27-39](#) is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameter page stream are ignored.

**Table 27-39. ONFI Parameters Page Description**

Offset	Description	Size (Bytes)
6	Features supported	2
80	Number of data bytes per page	4
84	Number of spare bytes per page	2
92	Number of pages per block	4
101	Number of address cycles	1

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI), then the device is reset again with polling for device to be ready (with 100-ms time-out). Then, the standard Read ID (command 90h/address 00h) is sent. If the Device ID (second byte of the ID byte stream) is recognized as being a supported device, then the device parameters are extracted from an internal ROM code table. [Table 27-40](#) lists the supported devices.

**Table 27-40. Supported NAND Devices**

Capacity	Device ID	Bus Width	Page Size in Bytes
512 Mb	F0h	8	2048
512 Mb	C0h	16	2048
512 Mb	A0h	8	2048
512 Mb	B0h	16	2048
512 Mb	F2h	8	2048
512 Mb	C2h	16	2048
512 Mb	A2h	8	2048
512 Mb	B2h	16	2048
1 Gb	F1h	8	2048
1 Gb	C1h	16	2048
1 Gb	A1h	8	2048
1 Gb	B1h	16	2048
2 Gb	DAh	8	2048 (4096)
2 Gb	CAh	16	2048 (4096)
2 Gb	AAh	8	2048 (4096)
2 Gb	BAh	16	2048 (4096)
2 Gb	83h	8	2048 (4096)
2 Gb	93h	16	2048 (4096)

**Table 27-40. Supported NAND Devices (continued)**

Capacity	Device ID	Bus Width	Page Size in Bytes
4 Gb	DCh	8	2048 (4096)
4 Gb	CCh	16	2048 (4096)
4 Gb	ACh	8	2048 (4096)
4 Gb	BCh	16	2048 (4096)
4 Gb	84h	8	2048 (4096)
4 Gb	94h	16	2048 (4096)
8 Gb	D3h	8	2048 (4096)
8 Gb	C3h	16	2048 (4096)
8 Gb	A3h	8	2048 (4096)
8 Gb	B3h	16	2048 (4096)
8 Gb	85h	8	2048 (4096)
8 Gb	95h	16	2048 (4096)
16 Gb	D5h	8	2048 (4096)
16 Gb	C5h	16	2048 (4096)
16 Gb	A5h	8	2048 (4096)
16 Gb	B5h	16	2048 (4096)
16 Gb	86h	8	2048 (4096)
16 Gb	96h	16	2048 (4096)
32 Gb	D7h	8	2048 (4096)
32 Gb	C7h	16	2048 (4096)
32 Gb	A7h	8	2048 (4096)
32 Gb	B7h	16	2048 (4096)
32 Gb	87h	8	2048 (4096)
32 Gb	97h	16	2048 (4096)
64 Gb	DEh	8	2048 (4096)
64 Gb	CEh	16	2048 (4096)
64 Gb	A Eh	8	2048 (4096)
64 Gb	B Eh	16	2048 (4096)

After retrieving parameters from the table, the page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices that are smaller than 2Gb have the block size parameter set to 128KB (when the page size is 2KB). [Table 27-41](#) shows the fourth ID data byte encoding used in the ROM code.

**Table 27-41. Fourth NAND ID Data Byte**

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
Page size	512 bytes							0	0
	2048 bytes							0	1
	4096 bytes							1	0
	8192 bytes							1	1
Cell type <sup>(1)</sup>	2 levels						0	0	
	4 levels						0	1	
	8 levels						1	0	
	16 levels						1	1	

<sup>(1)</sup> Read by ROM code only when the manufacturer code (first ID byte) is 98h

**Table 27-41. Fourth NAND ID Data Byte (continued)**

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
<b>Block size</b>	64KB			0	0				
	128KB			0	1				
	256KB			1	0				
	512KB			1	1				

Figure 27-22 shows the detection procedure. Once the NAND device is successfully detected, the ROM code changes the GPMC to 16-bit bus width, if necessary.

**Figure 27-22. NAND Device Detection**

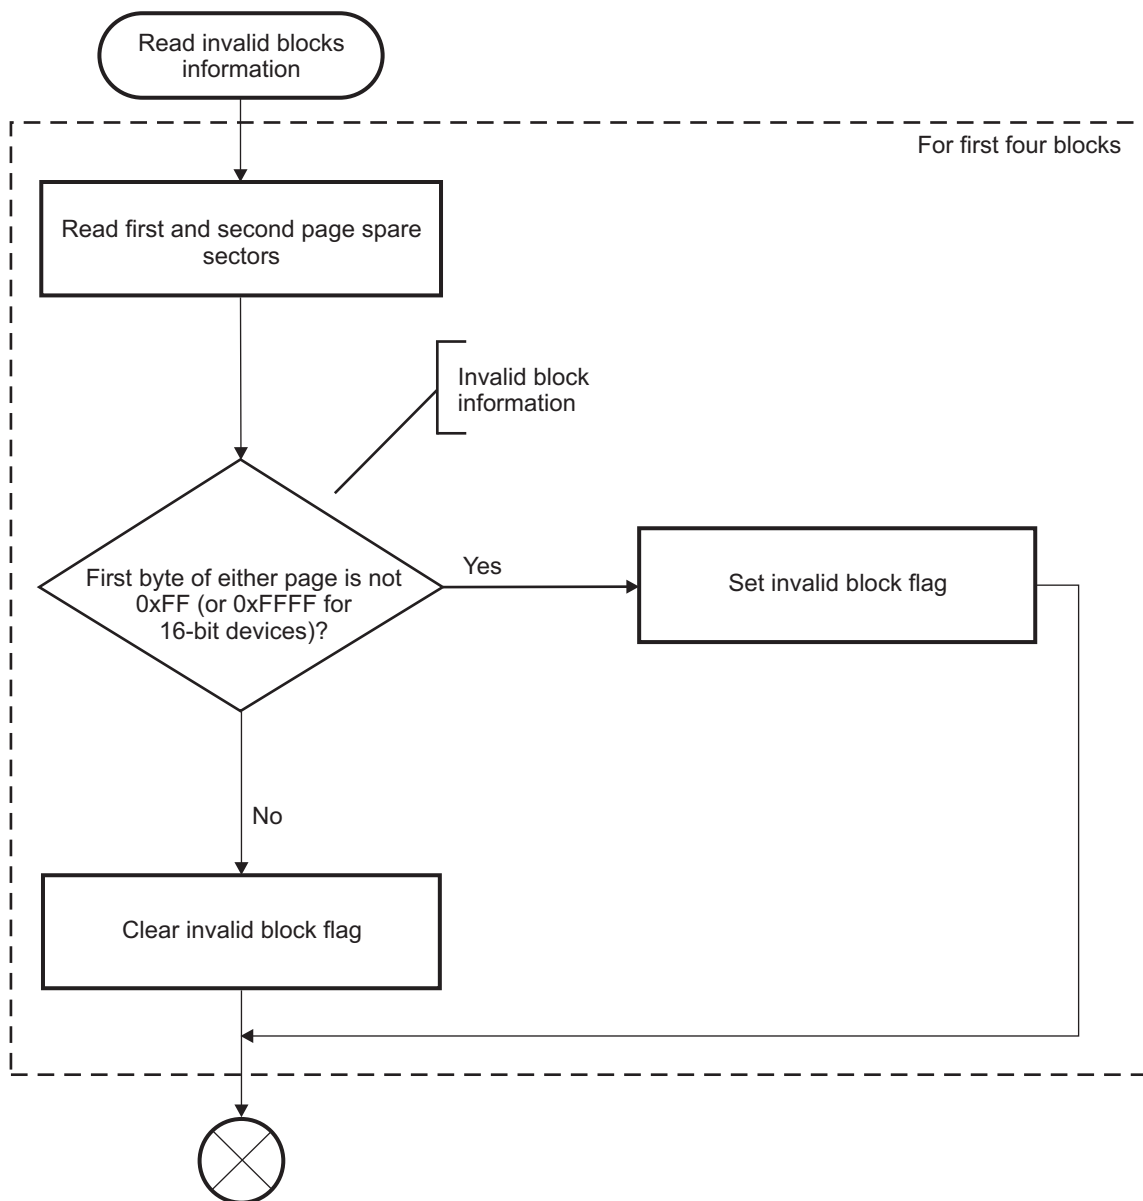

init-023

- **Bad block verification**  
 Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in the first and second pages for an 8-bit device/first word equal to FFFFh in the first and second pages for a 16-bit device).

Figure 27-23 shows the invalid block detection routine. The routine consists in reading spare areas and checking the validity data pattern.

**Figure 27-23. Bad NAND Invalid Block Detection**

init-033

**27.4.7.4.2 Read Sector Procedure**

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

The ROM code uses normal read (command 00h 30h) for reading NAND page data.

Page data can contain errors caused by memory alteration. The ROM code uses an ECC correction algorithm to detect and possibly correct those errors. The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, and CEh when the manufacturer code (first ID byte) is 98h, the cell type information is checked in the fourth byte of ID data. If it is equal to 10b, the ECC correction applied is BCH 16b/sector.

The BCH data is automatically calculated by the GPMC on reading each 512-byte sector. The computed ECC is compared against the ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. [Figure 27-24](#) and [Figure 27-25](#) show the mapping of ECC data inside the spare area for 2KB-page and 4KB- page devices, respectively. If both ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

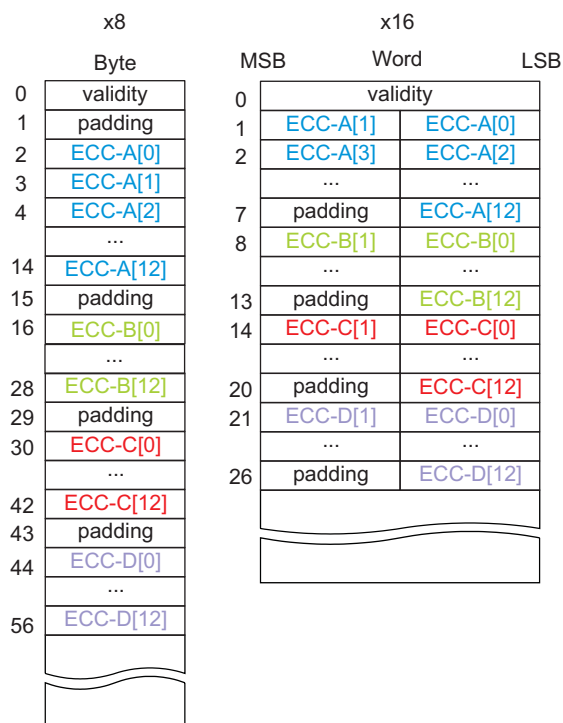

The first two bytes in the spare area are always reserved for block state information:

- First word equal to FFFFh for a 16-bit device to check block validity
- First byte equal to FFh for an 8-bit device to check block validity and the second byte is a padding

Concerning the length of ECC section in bytes, extra bytes can be added to make the access x16 compatible:

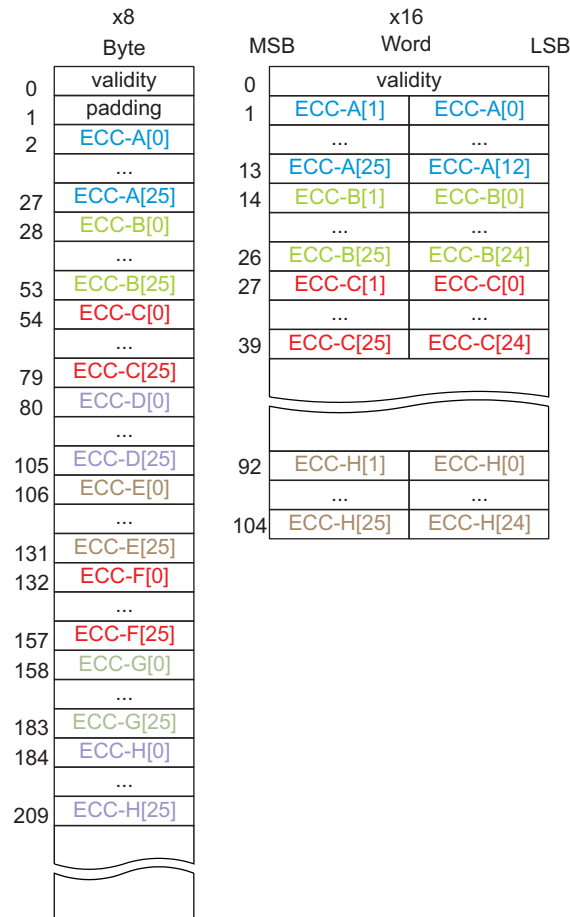

- For 8b BCH, there are 14 bytes ECC for each 512-byte sector (that is, 13 bytes ECC + 1 byte padding)
- For 16b BCH, there are 26 bytes ECC for each 512-byte sector (that is, no padding is needed)

**Figure 27-24. ECC Data Mapping for 2-KB Page and 8b BCH Encoding**

init-040

Figure 27-25. ECC Data Mapping for 4-KB Page and 16b BCH Encoding

init-041

### 27.4.7.5 OneNAND/Flex-OneNAND

The ROM code support for OneNAND/Flex-OneNAND devices has the following characteristics:

- Devices from 512 Mbits
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 50 MHz.
- The device is connected to GPMC CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc\_wait0 is not monitored.
- Four physical blocks are searched for an image. The block size is 128KB (typically).
- Data correction is fully handled by the OneNAND/FlexOneNAND device

The OneNAND/Flex-OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND/Flex-OneNAND memory booting, no user intervention is required. The information in the following sections is included for debugging. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

#### **27.4.7.5.1 Initialization and OneNAND/Flex-OneNAND Detection**

The initialization routine for OneNAND/Flex-OneNAND consists of two parts: GPMC initialization and device detection with parameter determination.

- GPMC initialization

The ROM code first initializes the GPMC interface in XIP mode (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled.

- Device detection and parameters

The ROM code identifies a OneNAND/Flex-OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory-mapped registers. The ROM code reads identification data using both methods and compares the results. When the comparison passes, the ROM code assumes that the OneNAND/Flex-OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (number and size of data buffers) and configures it for asynchronous mode (default).

#### **27.4.7.5.2 OneNAND/Flex-OneNAND Read Sector Procedure**

When booting requests a sector from the OneNAND/Flex-OneNAND device, the ROM code performs the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND/Flex-OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 27-26](#) shows this procedure.

Figure 27-26. OneNAND/Flex-OneNAND Read Sector

### 27.4.7.5.3 OneNAND/Flex-OneNAND Support Limitations

As described in [Section 27.4.7.5.1, Initialization and OneNAND/Flex-OneNAND Detection](#), the ROM code checks only the coherency of the device ID obtained by two different methods. There is no table of supported Flex-OneNANDs in ROM code. This removes any dependency of the ROM code on device IDs from different manufacturers. However, the driver works with the following assumption:

- Page size is assumed to be 2048 bytes, divided into four 512-byte sectors. In case of OneNAND/Flex-OneNAND, with 4096-byte pages, divided into eight sectors, users must program only the first sectors (sectors 0-3) of each page. Sectors 4-7 of each page are not considered by the driver.

### 27.4.7.6 eMMC/eSD Embedded Memories and MMC/SD Cards

The OMAP4460 device allows booting from eMMC/eSD embedded memories or MMC/SD cards connected to SD/MMC1 or SD/MMC2. The booting interface is selected by configuration of the sys\_boot pins.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code.

The MMC interface 1 supports 1.8-V/3-V digital I/Os. The selection on I/O voltage level is done using the PBIAS circuitry. The PBIAS reference level is sensed by the ROM code and PBIAS cell voltage setup appropriately before any communication with the device. The MMC interface 2 supports only 1.8-V digital I/Os.

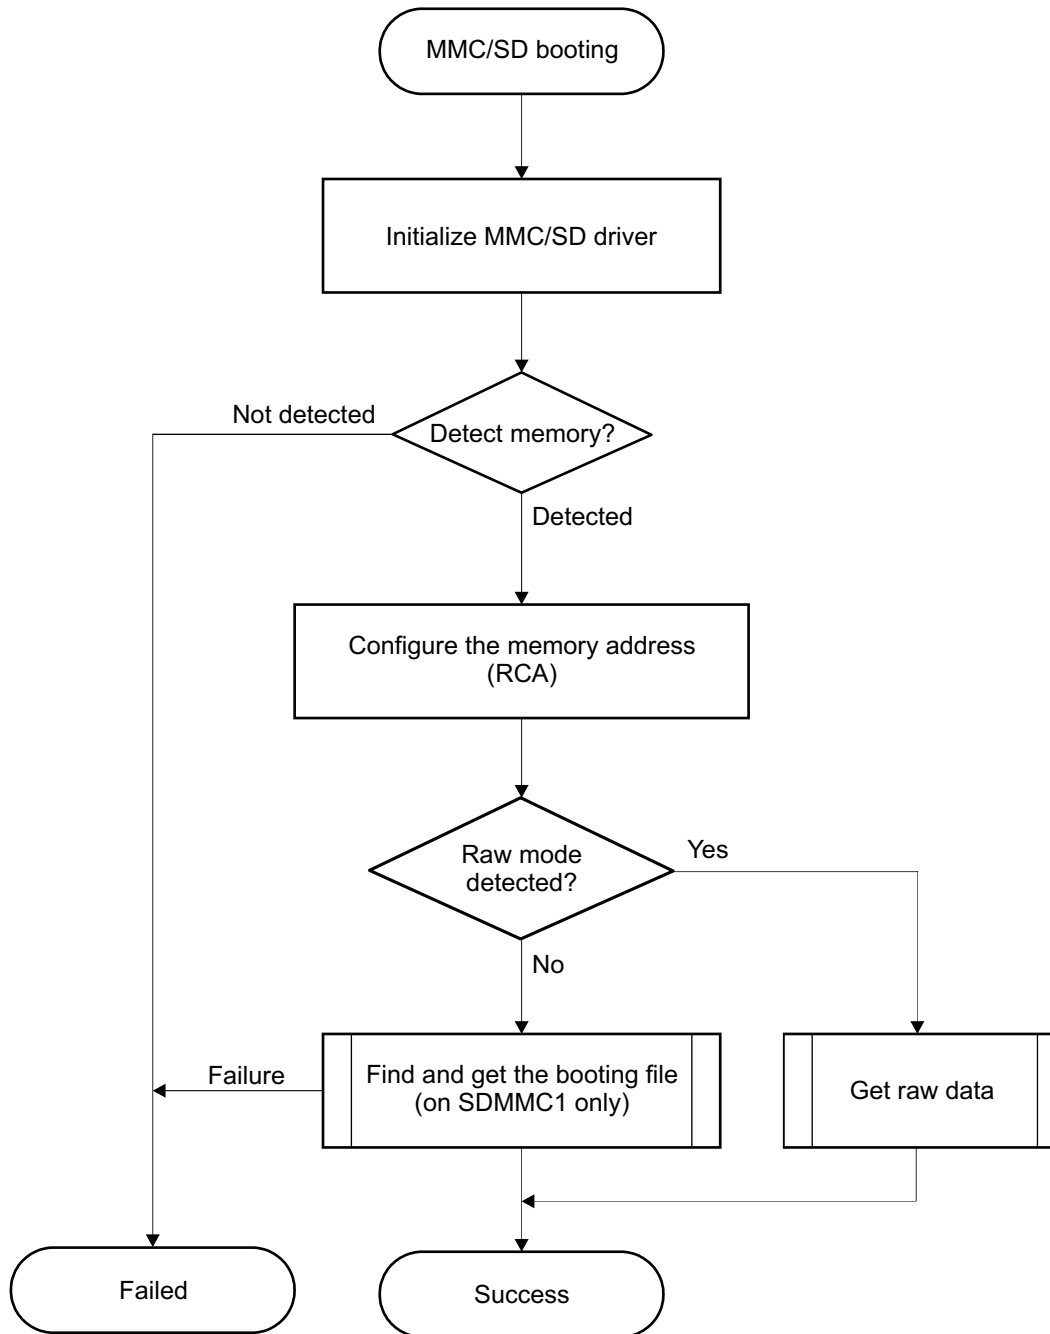

The OMAP4460 device supports two booting modes:

- Raw: The booting image data is read directly from sectors in the user area.
- File system (FAT12/16/32 supported with or without master boot record): The image data is read from a booting file.

When using the SDMMC1 interface, raw and file system modes are supported. When using the SDMMC2 interface, only raw mode is supported. The purpose of this approach is to avoid the boot time penalty of searching for a file system hierarchy when it is not always necessary.

[Figure 27-27](#) shows the complete procedure.

Figure 27-27. eMMC/eSD and MMC/SD Booting

init-016

27.4.7.6.1 eMMC/eSD Overview

The ROM code supports eMMC/eSD cards, with the following conditions:

- eMMC devices compliant with *Embedded MultiMediaCard (eMMC) eMMC/Card Product Standard, High Capacity, including Reliable Write Boot, and Sleep Modes, Dual Data Rate, Multiple Partitions Supports and Security Enhancement v4.41* from the MMCA Technical Committee. The exception is the hardware reset feature. If the user software requires MMC hardware reset, it can be accomplished with a GPIO.
- eSD devices compliant with *SD Specification Part 1 eSD (Embedded SD) Specification Addendum v2.1* from the SD Card Association

- The eMMC/eSD memory device is powered externally by a power-management IC or other power supply.
- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes
- Clock frequency:
  - Identification mode: 400 kHz
  - Data transfer mode: Up to 10 MHz, optionally up to 19.2 MHz
- Only one memory connected to the bus

#### 27.4.7.6.1.1 System Conditions and Limitations

The ROM code does not support the specific details of the partition management and boot operations modes as defined in the eMMC Standard sections *Partition Management* and *Boot Operation Mode*. The booting image is assumed to be in the User Data Area (no use of boot and/or RPMB partitions). Customers must set up the eMMC device appropriately so that the booting image is in a reliable area within the User Data Area (possibly with the Enhanced User Data Area property).

The ROM code does not provide a bus direction control signaling in case of using MMC interface 2 with level shifters.

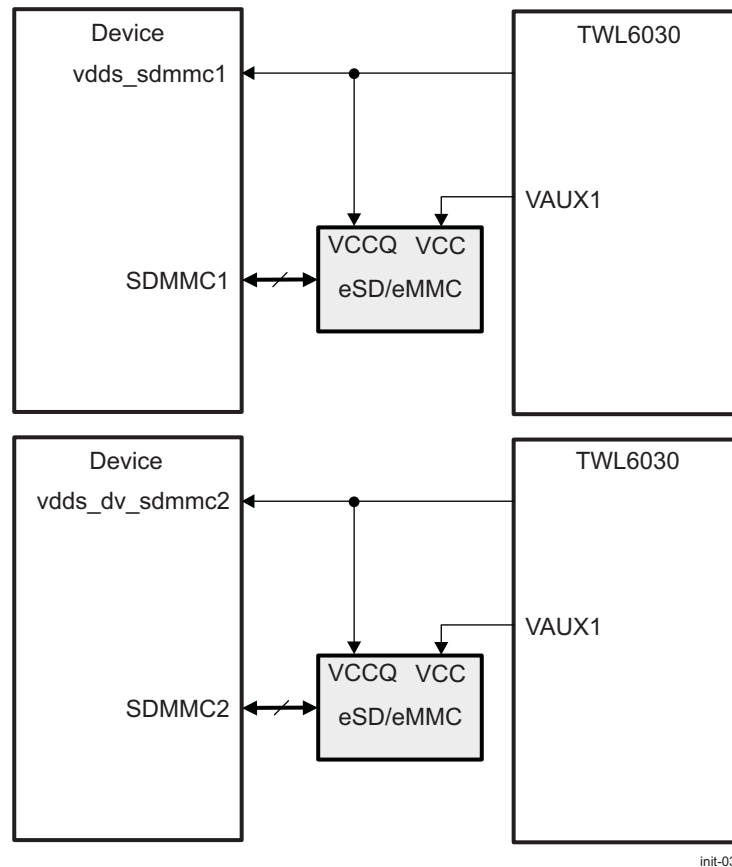

The ROM code expects that the eMMC device is powered externally and supplies are set and stable upon entering the booting procedure. The ROM code does not perform any software action to the companion device with respect to powering the eMMC/eSD device.

#### 27.4.7.6.1.2 eMMC/eSD Memory Connection

An eMMC/eSD device typically requires two supplies: one for the core memory array (selectable 1.8/2.9 V at TWL6030 BOOT2 pin level) (see TWL6030 documentation), and one for the device interface I/Os and controller (typical VCCQ = 1.8 V). Both memory device supply pins can possibly be merged into one, thus requiring only one power supply.

The SD/MMC2 interface shares the same balls as the GPMC interface. Therefore, the ROM code performs the necessary pin mux configuration to route the MMC signal through the GPMC balls.

[Figure 27-28](#) shows an example of the system connection between the power-management IC, memory device, and OMAP device.

**Figure 27-28. eMMC/eSD Connection**

The ROM code supports the muxing of MMC interface 2 through two paths:

- GPMC pins in configuration mode 1 (Mux1)
- SDMMC5/FREF\_CLKx pins in Mux5

The ROM code performs the necessary I/O pin muxing configuration to route the MMC2 signals through the appropriate pins depending on the selected SYSBOOT configuration.

#### 27.4.7.6.2 MMC/SD Overview

The ROM code supports booting from MMC/SD cards under the following conditions:

- MMC/SD cards compliant with *The MultiMediaCard System Specification* from the MMCA Technical Committee and the *SD Memory Card Specifications, File System Specification* from the SD Association. These include low- and high-capacity cards.
- MMC/SD cards connected to SDMMC interface 1
- 3-V VCC power supply, support for 3-V or 1.8-V I/O voltages
- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes
- Clock frequency:
  - Identification mode: 400 kHz
  - Data transfer mode: Up to 10 MHz (optionally up to 19.2 MHz)
- Only one card connected to the bus

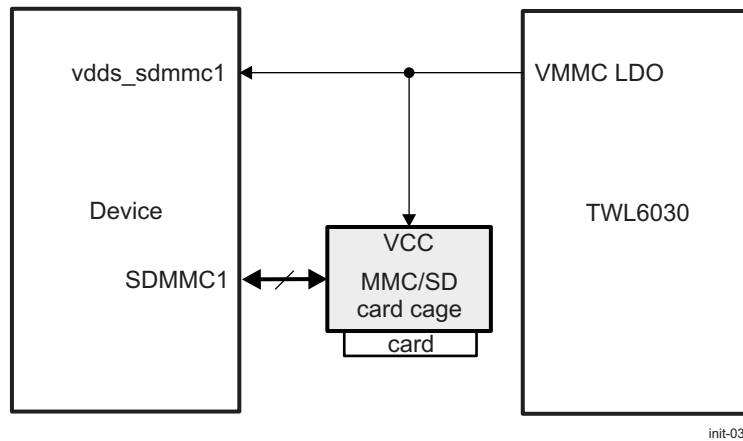

### 27.4.7.6.2.1 MMC/SD Card Connection

An SD/MMC card can be connected to the MMC1 interface, typically through a card cage. The ROM code sends the appropriate I<sup>2</sup>C sequence to the power-management IC to set the VMMC LDO to 3 V and switch it on.

Figure 27-29 shows the typical connection between the power IC, the card, and the OMAP device .

**Figure 27-29. MMC/SD Card Connection**

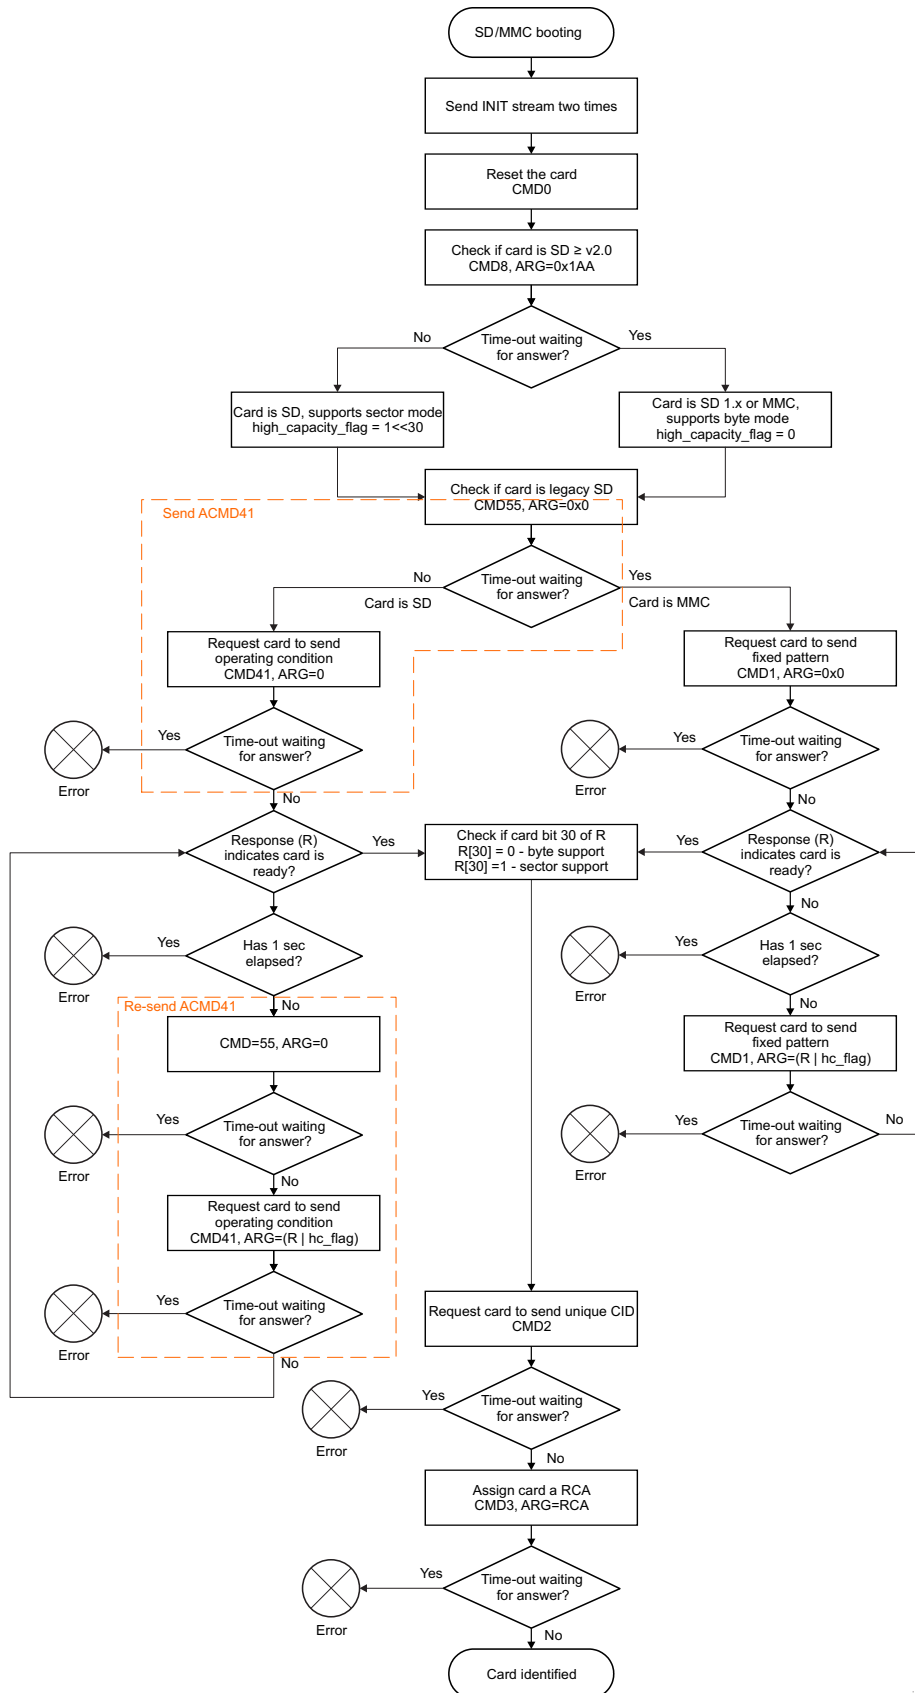

**NOTE:** The ROM code does not handle the card detection feature on the card cage.

### 27.4.7.6.3 Initialization and Detection

The ROM code initializes the memory device or card connected on the interface using the standard high-voltage range (3.0 V). If neither a card nor memory device is detected, the ROM code moves to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code assumes that only one memory or card is connected on the bus. This is done using the CMD line common to the SD and MMC memory devices. The MMC and SD standards describe this phase as the initialization phase.

Figure 27-30 shows the MMC/SD detection procedure.

Figure 27-30. MMC/SD Detection Procedure

int-026

#### 27.4.7.6.4 Read Sector Procedure

- Raw mode

In raw mode, an image can be at one of the four consecutive locations in the main area: offset 0x0 (0KB)/0x20000 (128KB)/0x40000 (256KB)/0x60000 (384KB). For this reason, the size of a booting image must not exceed 128KB. However, a device with an image greater than 128KB can be flash starting at one of the aforementioned locations. Therefore, the ROM code does not check the image size. The only drawback is that the image crosses the subsequent image boundary. Raw mode is detected by reading sectors 0, 256, 512, and 768. The content of these sectors is verified for the presence of a TOC structure. For a GP device, a CH (if used) must be in the first sector followed by a GP header. The CH can be void (containing only a CHSETTINGS item for which the Valid field is 0), as described in [Section 27.4.8.2, Configuration Header](#). Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is assumed.

- File system handling

File system support is available only for the SDMMC1 interface. The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can freely address sectors in the booting file space.

#### 27.4.7.6.5 File System Handling

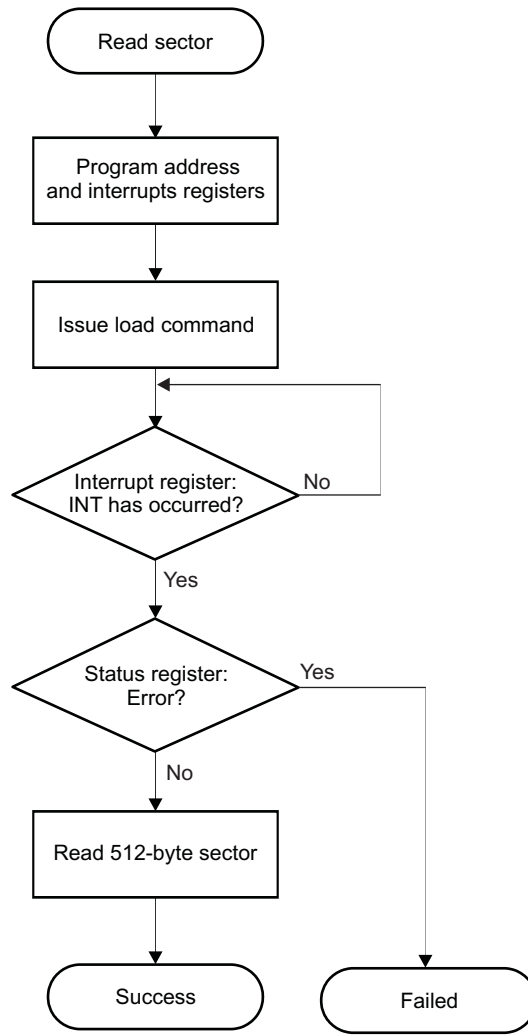

The MMC/SD cards can hold a file system that the ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an **active** primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 27-31](#) shows the complete process.

**Figure 27-31. SD/MMC Get Booting File**

init-025

### 27.4.7.6.5.1 MBR and FAT File System

This paragraph describes functions used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 27-42](#), and the partition table entry is described in [Table 27-43](#).

**Table 27-42. Master Boot Record Structure**

Offset	Length (Bytes)	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry
01FEh	2	Signature (0xAA55)

**Table 27-43. Partition Table Entry**

Offset	Length [Bytes]	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0]–Cs[9:8]–Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	16	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBA <sub>s</sub> = Cs.H.S + Hs.S + Ss–1
000Ch	4	Number of sectors in partition	LBA <sub>e</sub> = Ce.H.S + He.S + Se–1 Nb s= LBA <sub>e</sub> –LBA <sub>s</sub> + 1

SD/MMC booting consists of the following steps:

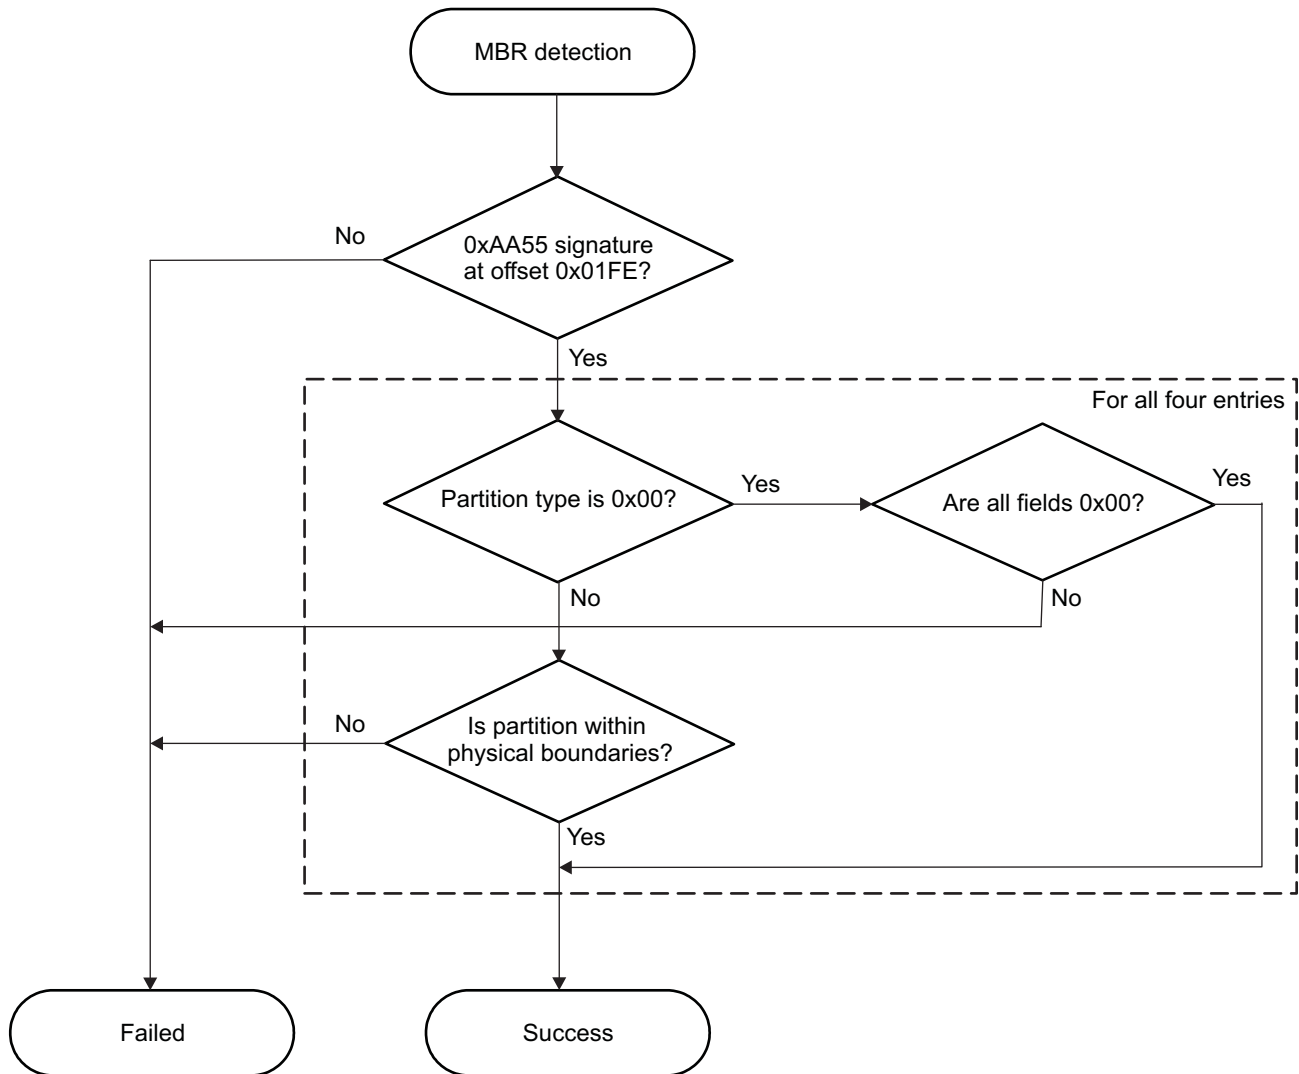

#### 1. MBR detection

The ROM code first checks whether the MBR signature is present, and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid, or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- If its type is set to 00h, all fields in the entry must be 00h.
- The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See [Figure 27-32](#) for more information about MBR detection.

Figure 27-32. MBR Detection Procedure

init-028

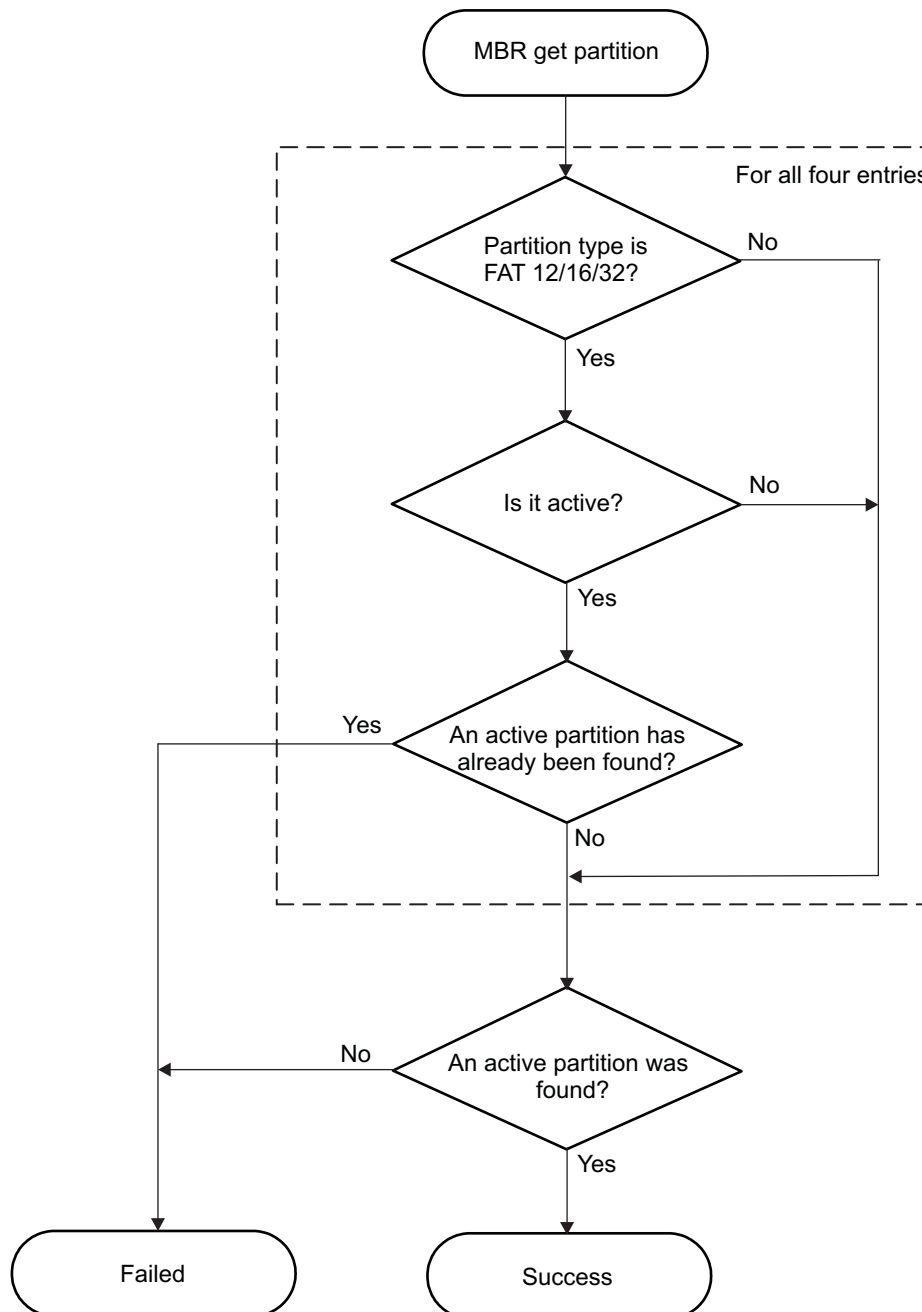

2. Get the MBR partition.

Once identified, the ROM code gets the partition using the procedure described in Figure 27-32. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or the test fails if there is more than one active partition. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, the ROM code returns with FAIL if another partition type is used (for instance, Linux FS) or if the partition is not valid.

The FAT file system consists of several parts:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. Figure 27-33 shows more about getting the partition.

**Figure 27-33. MBR, Get Partition**

init-029

### 3. Find the booting file.

When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB\_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by the following equation:

$$Cluster_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BPB\_NumFATs \cdot BPB\_FATSz + Cluster \cdot BPB\_SecPerCLus$$

init-E001

**NOTE:** BPB\_FatSz is BPB\_FatSz16 for FAT12/16, or BPB\_FatSz32 for FAT32.

**NOTE:** The BPB\_HiddSec field can contain 0, even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, etc.). (See [Table 27-44](#).)

**Table 27-44. FAT Directory Entry**

Offset	Length [Bytes]	Name	Description
0000h	11	DIR_Name	Short Name (8 + 3)
000Bh	1	DIR_Attr	File Attributes: 01h – ATTR_READ_ONLY 02h – ATTR_HIDDEN 04h – ATTR_SYSTEM 08h – ATTR_VOLUME_ID 10h – ATTR_DIRECTORY 20h – ATTR_ARCHIVE 0Fh – ATTR_LONG_NAME
000Ch	1	DIR_NTRes	Reserved. Set to 00h.
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created.
0010h	2	DIR_CrtDate	Date file was created.
0012h	2	DIR_LstAccDate	Last access date
0014h	2	DIR_FstClusHi	High word of the first cluster number of this entry
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of the first cluster number of this entry
001Ch	4	DIR_FileSize	File size in bytes

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR\_LONG\_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR\_FstClusHi/DIR\_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see [Table 27-44](#)) and length fixed by BPB\_RootEntCnt, which is the total of 32-byte entries. Therefore, handling this directory is straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. The way in which the FAT is handled is described in Step 4.

#### 4. Buffer FAT entries in the FAT buffer

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB\_HiddSec + BPB\_RsvdSecCnt + BP\_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB\_FATSz16 or BPB\_FATSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB\_ExtFlags[7]. If this flag is set, the FAT BPB\_ExtFlags[3:0] bit field is used. In this case, no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the

cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 27-45](#).

**NOTE:** For compatibility, cluster 0 and cluster 1 are not used for files, and these entries must contain:

- FF8h and FFFh (for FAT12)
- FFF8h and FFFFh (for FAT16)
- 0FFFFFFF8h and 0FFFFFFFh (for FAT32)

**Table 27-45. FAT Entry Description**

FAT12	FAT16	FAT32	Description
000h	0000h	00000000h	Free cluster
001h	0001h	00000001h	Reserved cluster
002h–FEFh	0002h– FFEFh	00000002h– 0FFFFFFEFh	Used cluster; value points to next cluster
FF0h–FF6h	FFF0h– FFF6h	0FFFFFFF0h– 0FFFFFFF6h	Reserved values
FF7h	FFF7h	0FFFFFFF7h	Bad cluster
FF8h–FFFh	FFF8h– FFFFh	0FFFFFFF8h– 0FFFFFFFh	Last cluster in file

**NOTE:** FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB\_SecPerClus). This buffer is used later by the booting procedure to access the file.

## 27.4.8 Image Format

### 27.4.8.1 Overview

An image has two major parts:

- AAn optional CH
- Software to execute

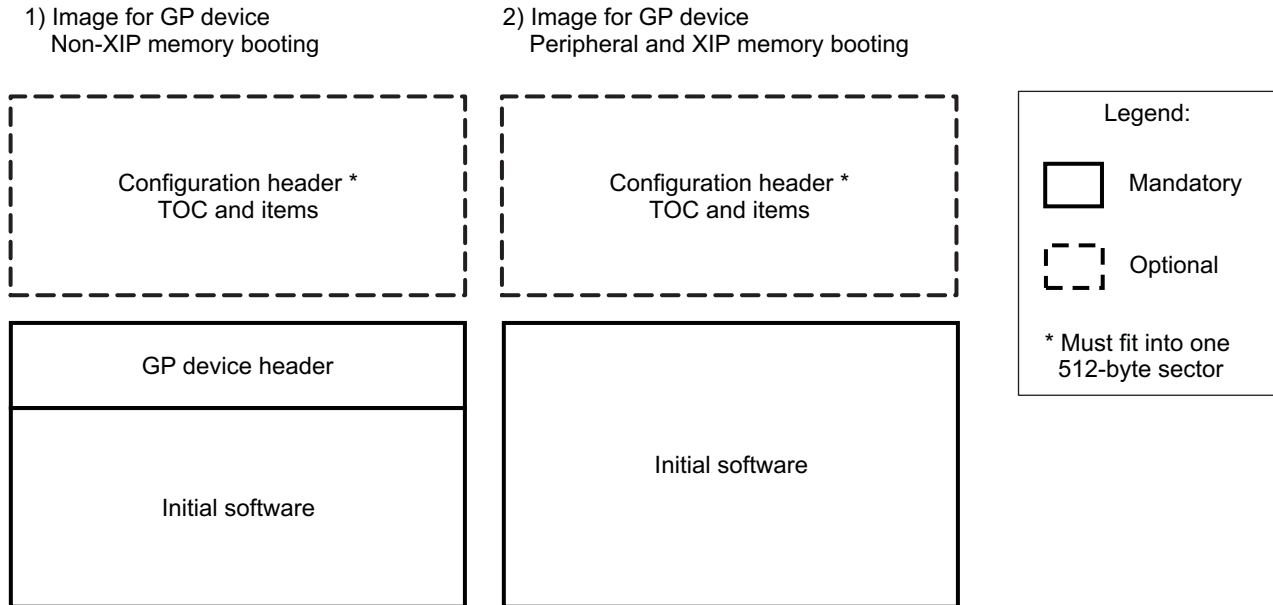

The CH can contain several parameters set by users to speed up booting. It is further described in [Section 27.4.8.2, Configuration Header](#).

The second part contains the software that is loaded into the memory and executed.

[Figure 27-34](#) is an overview of the boot image formats. There are two image types:

1. GP non-XIP memory booting: This image type is used for memories that require shadowing (for example, MMC). An image can contain a CH that includes at least a CHSETTINGS item entry. Next, there must be a small header (referred to as a GP header) that contains information about the size and the destination address.
2. When the memory device is of XIP type (for example, NOR), the GP header is not required, and the image can contain code for direct execution. Optionally, the first sector can contain a CH. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

**Figure 27-34. Image Formats**

init-018

### 27.4.8.2 Configuration Header

The ROM code default settings (such as clock frequencies, EMIF, GPMC, or MMCHS interfaces) can be tuned by the user by using the CH.

The CH can contain the following parts:

- Settings: Various clock settings (mandatory)
- RAM: EMIF settings
- FLASH: Flash interface (GPMC) settings
- MMC/SD: MMCHS interface settings

The beginning of the CH is a table of contents (TOC), which points to each item. This is described in [Figure 27-35](#). Each TOC item is a simple structure described in [Table 27-46](#). The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Next, the TOC is identified and searched until a 0xFFFF FFFF offset is found. The CH is read and parameters are executed sequentially.

For the sake of simplicity, each field represents the content of a register to be modified. Only fields required for the configuration are used; fields for status, for instance, are not modified and therefore are not shown in the tables.

**Figure 27-35. CH Format**

init-019

**Table 27-46. CH TOC Item**

Offset	Field	Size (Bytes)	Description
0x0000	Start	4	Offset from the start address of the TOC to the actual address of item contents
0x0004	Size	4	Size of item
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused
0x0010	Reserved	4	Unused
0x0014	Filename	12	12-character name of a item, including the zero termination character(\0)

### 27.4.8.2.1 CHSETTINGS Item

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the OMAP clocking to some default settings as described in [Section 27.4.4.2, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clock settings.

[Table 27-47](#) describes the fields. The clocking procedure and the clocking setting structure are described in [Section 27.4.4.4, Software Booting Configuration](#).

**Table 27-47. CHSETTINGS Item**

Offset	Field	Description
0000h	Section key	Key used for item verification: C0C0C0C1h
0004h	Valid	Enables/disables the section: 00h: Disable

**Table 27-47. CHSETTINGS Item (continued)**

Offset	Field	Description
		Others: Enable
0005h	Version	Configuration header version 01h Others: Reserved
0006h	Reserved	
0008h	Clocking settings	Described in <a href="#">Table 27-16</a> starting from the FLAGS field.

### 27.4.8.2.2 CHRAM Item

The CHRAM configuration header contains settings specific to the SDRAM memory controller (EMIF). [Table 27-48](#) describes the fields. The ROM code does not configure the EMIF by default, because it cannot assume any external SDRAM type. Therefore, if the ROM code is needed to configure the SDRAM access, the user must provide the appropriate timing details in the CHRAM structure. For more information, see [Section 15.3, EMIF Controller](#), and [Section 15.3.6, EMIF Register Manual](#).

**Table 27-48. CHRAM Item**

Offset	Field	Description
0000h	Section key	Key used for section verification: C0C0C0C2h.
0004h	Valid	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	
0008h	SdramConfig (EMIF1)	SDRAM configuration register (EMIF1.EMIF_SDRAM_CONFIG)
000Ch	SdramRefresh (EMIF1)	SDRAM Refresh control register (EMIF1.EMIF_SDRAM_REF_CTRL)
0010h	SdramTim1 (EMIF1)	SDRAM timing 1 register (EMIF1.EMIF_SDRAM_TIM_1)
0014h	SdramTim2 (EMIF1)	SDRAM timing 2 register (EMIF1.EMIF_SDRAM_TIM_2)
0018h	SdramTim3 (EMIF1)	SDRAM timing 3 register (EMIF1.EMIF_SDRAM_TIM_3)
001Ch	PwrMgtCtrl (EMIF1)	Power-management control register (EMIF1.EMIF_PWR_MGMT_CTRL)
0020h	DdrPhyCtrl1 (EMIF1)	DDR PHY control 1 register (EMIF1.EMIF_DDR_PHY_CTRL_1)
0024h	DdrPhyCtrl2 (EMIF1)	DDR PHY control 2 register (EMIF1.EMIF_DDR_PHY_CTRL_2)
0028h	ModeReg1 (EMIF1)	Mode register MR1 (in the LPDDR2 device)
0029h	ModeReg2 (EMIF1)	Mode register MR2 (in the LPDDR2 device)
002Ah	ModeReg3 (EMIF1)	Mode register MR3 (in the LPDDR2 device)
002Bh	Reserved	
002Ch	SdramConfig (EMIF2)	SDRAM configuration register (EMIF2.EMIF_SDRAM_CONFIG)
0030h	SdramRefresh (EMIF2)	SDRAM refresh control register (EMIF2.EMIF_SDRAM_REF_CTRL)
0034h	SdramTim1 (EMIF2)	SDRAM timing 1 register (EMIF2.EMIF_SDRAM_TIM_1)
0038h	SdramTim2 (EMIF2)	SDRAM timing 2 register (EMIF2.EMIF_SDRAM_TIM_2)
003Ch	SdramTim3 (EMIF2)	SDRAM timing 3 register (EMIF2.EMIF_SDRAM_TIM_3)
0040h	PwrMgtCtrl (EMIF2)	Power-management control register (EMIF2.EMIF_PWR_MGMT_CTRL)
0044h	DdrPhyCtrl1 (EMIF2)	DDR PHY control 1 register (EMIF2.EMIF_DDR_PHY_CTRL_1)
0048h	DdrPhyCtrl2 (EMIF2)	DDR PHY control 2 register (EMIF2.EMIF_DDR_PHY_CTRL_2)
004Ch	ModeReg1 (EMIF2)	Mode register MR1 (in the LPDDR2 device)
004Dh	ModeReg2 (EMIF2)	Mode register MR2 (in the LPDDR2 device)
004Eh	ModeReg3 (EMIF2)	Mode register MR3 (in the LPDDR2 device)
004Fh	Reserved	
0050h	DMM LISA Map 0	DMM LISA section 0 mapping (see <a href="#">Section 15.2</a> for more information about the DMM module architecture)

**Table 27-48. CHRAM Item (continued)**

Offset	Field	Description
0054h	Flags	Setting bits 0 to 3 requests ROM code to configure the appropriate channel/chip select: Bit[0]: Configure EMIF1 CS0 Bit[1]: Configure EMIF1 CS1 Bit[2]: Configure EMIF2 CS0 Bit[3]: Configure EMIF2 CS1  Bits[8:11]: EMIF temperature monitoring timeout. If the value is non-zero, the ROM code checks the MR4 register of the EMIF LPDDR2. As long as the SDRAM Refresh Rate field is not 0x3 (Temperature not $\leq 85^{\circ}\text{C}$ ) it indicates an abnormal EMIF temperature state and the ROM code loops. When the SDRAM Refresh Rate goes back to 0x3, the ROM code resumes EMIF initialization. The waiting loop cannot exceed the timeout value indicated by this flag. When the timeout expires, the ROM code resumes EMIF initialization.  0x0: No temperature monitoring 0x1: Timeout 1 second 0x2: Timeout 2 seconds 0x3: Timeout 3 seconds 0x5: Timeout 5 seconds 0xA: Timeout 10 seconds Other bits: Reserved

**NOTE:**

- The ROM code supports only the LPDDR2 memory type (as set in the SDRAM configuration register).
- It is assumed that the same kind of SDRAM (same type and timings) is attached to both CSs when requesting the configuration of both CSs for a given EMIF (for example, if bits 0 and 1 of the Flags field are set, it is assumed that both EMIF1 CSs are attached to the same kind of memory).

**27.4.8.2.3 CHFLASH Item**

The CHFLASH configuration header contains settings specific to the general-purpose memory controller (GPMC). For more information, see [Section 15.4, GPMC Overview](#). [Table 27-49](#) describes the fields.

**Table 27-49. CHFLASH Item**

Offset	Field	Description
0000h	Section Key	Key used for section verification: C0C0C0C3h.
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Reserved	
0008h	GPMC_SYSCONFIG (LSB)	Register values
000Ah	GPMC_IRQENABLE (LSB)	
000Ch	GPMC_TIMEOUT_CONTROL (LSB)	
000Eh	GPMC_CONFIG (LSB)	
0010h	GPMC_CONFIG1_0	
0014h	GPMC_CONFIG2_0	
0018h	GPMC_CONFIG3_0	
001Ch	GPMC_CONFIG4_0	
0020h	GPMC_CONFIG5_0	

**Table 27-49. CHFLASH Item (continued)**

Offset	Field	Description
0024h	GPMC_CONFIG6_0	
0028h	GPMC_CONFIG7_0	
002Ch	GPMC_PREFETCH_CONFIG1	
0030h	GPMC_PREFETCH_CONFIG2 (LSB)	
0032h	GPMC_PREFETCH_CONTROL (LSB)	
0034h	GPMC_ECC_CONFIG	
0036h	GPMC_ECC_CONTROL	
0038h	GPMC_ECC_SIZE_CONFIG (LSB)	
003Ch	Enable_A1_A10	0: Do not change A1– A10 pads Others: Enable A1– A10 pads

#### 27.4.8.2.4 CHMMCS D Item

The CHMMCS D configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see [Chapter 24, MMC/SD/SDIO](#). [Table 27-50](#) describes the fields.

**Table 27-50. CHMMCS D Item**

Offset	Register Modified	Description
0000h	Section key	Key used for section verification C0C0C0C4h
0004h	Valid	Enables/disables the section: 00h: Disable Other: Enable
0005h	Reserved	
0008h	MMCHS_SYSCTRL(MSW)	Update MMCHS SYSCTRL interface register with the value specified in these fields. The register is not updated if the value is 0xFFFFFFFF.
000Ah	MMCHS_SYSCTRL(LSW)	
000Ch	MMCHS interface bus width	1: 1 bit 2: 4 bits 4: 8 bits 0xFFFF FFFF: Do not update bus width. Others: Reserved

The ROM code provides a booting parameter structure to the initial software (see [Section 27.4.8.4, Image Execution](#)). This structure contains a field that indicates whether the configuration header items have been correctly processed. For a CHMMCS D item, if the MMCHS\_SYSCTRL and bus width fields are set to 0xFFFF FFFF, the booting parameters report that the CHMMCS D section has not been executed, regardless of the value of the Valid field.

#### 27.4.8.3 GP Header

When the booting memory device is non-XIP (for example, MMC) the image must contain a small header, located before the executable code, and having the size of the software to load and the destination address of where to store it. [Table 27-51](#) describes the image format. The GP header is not required when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

**Table 27-51. GP Header Format**

Field	Non-XIP Device Offset	XIP Device Offset	Size (Bytes)	Description
Size	0x0000	–	4	Size of the image
Destination	0x0004	–	4	Address where to store the image or code entry point
Image	0x0008	0x0000	x	Executable code

**NOTE:** The Destination address field stands for:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

Users must take care to locate the code entry point to the target address for image copy.

#### 27.4.8.4 Image Execution

The image is executed when the ROM code performs the branch to the first executable instruction in the initial software. For a GP device in non-XIP, the execution address is the first word after the GP header. The branch is performed in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting execution. [Table 27-52](#) shows the booting parameter structure.

**Table 27-52. Booting Parameter Structure**

Offset	Field	Size (Bytes)	Description
0x00	Booting message	4	Last received booting message
0x04	Memory booting device descriptor	4	Pointer to the memory device descriptor that has been used during the memory booting process
0x08	Current booting device	1	Code of device used for booting: 0x00: Void, no device 0x02: XIP memory 0x02: XIPWAIT memory (wait-signal monitoring on) 0x03: NAND 0x04: OneNAND 0x05: MMC1 0x06: MMC2(1) 0x07: MMC2(2) 0x43: UART3 0x45: USB(1) (internal transceiver) 0x46: USB-ULPI 0x47: USB(2) (internal transceiver) Others: Reserved
0x09	Reset reason	1	Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset [1]: Global software warm reset [2]: Reserved [3]: MPU watchdog or WDTIMER2 reset [4]: Reserved [5]: External warm reset [6]: VDD MPU voltage manager reset

**Table 27-52. Booting Parameter Structure (continued)**

Offset	Field	Size (Bytes)	Description
			[7]: VDD IVA voltage manager reset [8]: VDD Core voltage manager reset [9]: ICEPick reset Other bits: Reserved
0x0A	CH flags	1	Configuration header items flag. Each item is described by 1 bit. A set bit indicates that the item was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMCS Other bits: Reserved

### 27.4.9 Tracing

Tracing in the public ROM code consists in three 32-bit vectors for which each bit corresponds to a particular way point in the ROM code execution sequence. [Table 27-53](#) through [Table 27-55](#) list the organization of the tracing data in RAM. Tracing vectors are initialized at the beginning of the start-up phase and are updated all along the boot process.

There are two sets of tracing vectors ([Table 27-13](#)). The first set is the current trace information (after a cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM code run after a cold reset. As a result, after a warm reset it is possible to have visibility on the boot scenario that occurred during a cold reset.

[Table 27-53](#) lists the organization of tracing vector 1.

**Table 27-53. Tracing Vector 1**

Bit	Group	Meaning
0	General	Passed the public reset vector
1	General	Entered main function
2	General	Running after the cold reset
3	Boot	Main booting routine entered
4	Memory boot	Memory booting started
5	Peripheral boot	Peripheral booting started
6	Boot	Booting loop reached last device
7	Boot	GP header (non-XIP) found
8	Boot	Booting message Skip peripheral booting received
9	Boot	Booting message Change device received
10	Peripheral boot	Booting message Peripheral booting received
11	Peripheral boot	Booting message Get ASIC ID received
12	Peripheral boot	Device initialized
13	Peripheral boot	ASIC ID sent
14	Peripheral boot	Image received
15	Peripheral boot	Peripheral booting failed
16	Peripheral boot	Booting message not received (time-out)
17	Peripheral boot	Image size not received (time-out)
18	Peripheral boot	Image not received (time-out)
19	Reserved	
20	Configuration header	CHSETTINGS found

**Table 27-53. Tracing Vector 1 (continued)**

Bit	Group	Meaning
21	Configuration header	CHSETTINGS executed
22	Configuration header	CHRAM executed
23	Configuration header	CHFLASH executed
24	Configuration header	CHMMCSDB clocks executed
25	Configuration header	CHMMCSDB bus width executed
26	Reserved	
27	Reserved	
28	Software booting configuration	SWCFG general detected
29	Software booting configuration	SWCFG clocks detected
30	Software booting configuration	SWCFG time-out detected
31	Reserved	

Table 27-54 lists the organization of tracing vector 2.

**Table 27-54. Tracing Vector 2**

Bit	Group	Meaning
0	Power-management IC	TWL6030 detected
1	Power-management IC	VBUS detected (in TWL6030)
2	Power-management IC	VMMC 3 V switched on (in TWL6030)
3	Power-management IC	VUSB 3.3 V switched on (in TWL6030)
4	USB	USB connect
5	USB	USB configured state
6	USB	USB VBUS valid (in USBOTGHS)
7	USB	USB session valid
8	Power-management IC	PrevStartOk set
9	USB	Suspend event
10	USB	Resume event
11	USB	Charger detected
12	Memory boot	Memory booting trial 0
13	Memory boot	Memory booting trial 1

## 27.5 Services for HLOS Support

The ROM code provides different services that can be called on GP devices for L2 cache maintenance, wake up of slave CPU(s), etc. These services are implemented in monitor mode (the service must be called by writing the function ID into the R12 register and using the SMC instruction) and do not use any resources like RAM/stack or hardware outside the master CPU. The caller must ensure the save and restore of the processor registers before and after calling the monitor service.

The following code example shows how the monitor ROM code functions can be accessed by an application running in public mode:

```

;----- ;
FUNCTION: PL310_SetDebugL2Cache
;
; DESCRIPTION: Function calls the Monitor Service to configure the debug
;               control register of the L2 cache.
;
; INPUTS: r0 Value to set in the debug control register
;
; RETURN:
;
;-----
PL310_SetDebugL2Cache FUNCTION
    PUSH {R1-R12, LR}
    LDR R12, =API_MONITOR_L2CACHE_SETDEBUG_INDEX
    SMC 0x1
    POP {R1-R12, PC}
ENDFUNC

```

### 27.5.1 L2 Cache Maintenance

**Table 27-56. L2 Cache Write Debug Register**

Function ID	Description	
R12 = 0x100	This function sets the input parameter value in the L2 Cache Debug register.	
Parameters		
Type	Location	Description
Input	R0	Debug register value to set
Output		
Return		

**Table 27-57. L2 Cache Clean and Invalidate Range of Physical Address**

Function ID	Description	
R12 = 0x101	This function cleans and invalidates a range Physical Addresses. This is a workaround of the clean and invalidate L2 cache.	
Parameters		
Type	Location	Description
Input	R0 R1	Physical Start Address of the range Size of the range to invalidate
Output		
Return		

**Table 27-58. Enable/Disable L2 Cache**

Function ID	Description
R12 = 0x102	This function sets the given input value in the L2 Cache Control register (enable/disable)

**Table 27-58. Enable/Disable L2 Cache (continued)**

Function ID	Description	
<b>Parameters</b>		
Type	Location	Description
Input	R0	Control register value to set
Output		
Return		

**Table 27-59. Write Auxiliary Control Register**

Function ID	Description	
R12 = 0x109	This function writes the PL310 Auxiliary Control register with the input given value in R0.	
<b>Parameters</b>		
Type	Location	Description
Input	R0	Value to set in the register
Output		
Return		

**Table 27-60. Write Tag and Data RAM Latency Control Register**

Function ID	Description	
R12 = 0x112	This function writes the PL310 Tag and Data RAM Latency Control Register with the input given value in R0 and R1.	
<b>Parameters</b>		
Type	Location	Description
Input	R0 R1	Tag RAM latency to set Data RAM latency to set
Output		
Return		

**Table 27-61. Write Prefetch Control Register**

Function ID	Description	
R12 = 0x113	This function writes the PL310 prefetch control register with the input given value in R0.	
<b>Parameters</b>		
Type	Location	Description
Input	RO	Value to set in the register
Output		
Return		

## 27.5.2 Multicore Infrastructure Maintenance

**Table 27-62. Read AUX\_CORE\_BOOT\_0 and AUX\_CORE\_BOOT\_1 Registers**

Function ID	Description	
R12 = 0x103	This function reads both AUX_CORE_BOOT_0/1 registers. The function is kept for compatibility with OMAP4430 ES1.0. AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 have memory-mapped access. See <a href="#">Chapter 4, Dual Cortex-A9 Subsystem</a> .	
<b>Parameters</b>		

**Table 27-62. Read AUX\_CORE\_BOOT\_0 and AUX\_CORE\_BOOT\_1 Registers (continued)**

Function ID	Description	
Type	Location	Description
Input		
Output	R0 R1	AUX_CORE_BOOT_0 register value AUX_CORE_BOOT_1 register value
Return		

**Table 27-63. Modify AUX\_CORE\_BOOT\_0**

Function ID	Description	
R12 = 0x104	This function modifies the AUX_CORE_BOOT_0 register used as a status bit. The function sets and clears the bit given in the parameter and returns the new register value after operation. This function is kept for compatibility with OMAP4430 ES1.0. AUX_CORE_BOOT_0 has memory-mapped access. See <a href="#">Chapter 4, Dual Cortex-A9 Subsystem</a> .	
Parameters		
Type	Location	Description
Input	R0 R1	Bit mask to set Bit mask to clear
Output		
Return	R0	AUX_CORE_BOOT_0 register new value

**Table 27-64. Write AUX\_CORE\_BOOT\_1**

Function ID	Description	
R12 = 0x105	This function sets the value of the AUX_CORE_BOOT_1 register value used to give the CPU1 boot address. The given address can be virtual or physical. CPU1 MMU must be enabled before jumping to this address. This function is kept for compatibility with OMAP4430 ES1.0. AUX_CORE_BOOT_1 has memory-mapped access. See <a href="#">Chapter 4, Dual Cortex-A9 Subsystem</a> .	
Parameters		
Type	Location	Description
Input	R0	Value to set in the register
Output		
Return		

**Table 27-65. Read WKG\_CONTROL\_0/1 Register**

Function ID	Description	
R12 = 0x106	This function returns the value of the WKG_CONTROL_0/1 register (CPU0 or CPU1) depending on the input parameter value. The function is kept for compatibility with OMAP4430 ES1.0. See the memory mapping and description in <a href="#">Chapter 4, Dual Cortex-A9 Subsystem</a> .	
Parameters		
Type	Location	Description
Input	R0	CPU ID
Output		
Return	R0	Value of the WKG_CONTROL_0/1 register

**Table 27-66. Clear WKG\_CONTROL\_0/1 Register**

Function ID	Description	
R12 = 0x107	This function clears the given bit mask of the WKG_CONTROL_0/1 register depending on the CPU ID.	
Parameters		
Type	Location	Description
Input	R0 R1	CPU ID Bit mask to clear
Output		
Return		

### 27.5.3 Snoop Control Unit (SCU)

**Table 27-67. Set Power Status Register**

Function ID	Description	
R12 = 0x108	This function sets the power status register of the CPU and cleans the full CPU L1 data cache, if the cache will be switched off when CPU enters into low-power state.	
Parameters		
Type	Location	Description
Input	R0 R1	CPU power state value to set (0x2: CSWRET, 0x3: OFF) L1 data cache state (0x00: RET, 0xFF: OFF)
Output		
Return		

### 27.5.4 Lockdown Translation Lookaside Buffers (TLBs)

**Table 27-68. Select the TLB Entry for Read**

Function ID	Description	
R12 = 0x10A	This function writes the Select Lockdown TLB Entry for Read register.	
Parameters		
Type	Location	Description
Input	R0	TLB entry
Output		
Return		

**Table 27-69. Select the TLB Entry for Write**

Function ID	Description	
R12 = 0x10B	This function writes the Select Lockdown TLB Entry for Write register.	
Parameters		
Type	Location	Description
Input	R0	TLB entry
Output		
Return		

**Table 27-70. Read the TLB VA Entry**

Function ID	Description	
R12 = 0x10C	This function reads the Lockdown TLB VA register (Selected TLB Entry for Read).	
Parameters		
Type	Location	Description
Input		
Output		
Return	R0	Value of the register

**Table 27-71. Write the TLB VA Entry**

Function ID	Description	
R12 = 0x10D	This function writes the Lockdown TLB VA register (Selected TLB Entry for Write). The NS bit is forced to 1.	
Parameters		
Type	Location	Description
Input	R0	Value to write
Output		
Return		

**Table 27-72. Read the TLB PA Entry**

Function ID	Description	
R12 = 0x10E	This function reads the Lockdown TLB PA register (Selected TLB Entry for Read).	
Parameters		
Type	Location	Description
Input		
Output		
Return	R0	Value of the register

**Table 27-73. Write the TLB PA Entry**

Function ID	Description	
R12 = 0x10F	This function writes the Lockdown TLB PA register (Selected TLB Entry for Write).	
Parameters		
Type	Location	Description
Input	R0	Value to write
Output		
Return		

**Table 27-74. Read the TLB Attributes Entry**

Function ID	Description	
R12 = 0x110	This function reads the Lockdown TLB Attributes register (Selected TLB Entry for Read).	
Parameters		
Type	Location	Description
Input		
Output		

**Table 27-74. Read the TLB Attributes Entry (continued)**

Function ID	Description	
Return	R0	Value of the register

**Table 27-75. Write the TLB Attributes Entry**

Function ID	Description	
R12 = 0x111	This function writes the Lockdown TLB Attributes register (Selected TLB Entry for Write). The NS bit is forced to 1.	
Parameters		
Type	Location	Description
Input	R0	Value to write
Output		
Return		

## On-Chip Debug Support

This chapter describes the on-chip debug support.

## 28.1 Introduction

Debugging a system containing an embedded processor involves an environment that connects high-level debugging software, executing on a host computer, to a low-level debug interface supported by the target device. In between these levels is a debug and trace controller (DTC) that facilitates communication between the host debugger and the debug support logic on the target chip.

A combination of hardware and software that connects the host debugger to the target system, the DTC uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG® commands and scans that execute the core hardware.

The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors.

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

For easy integration into applications, a set of libraries (APIs) for debug-IP programming and a software message library are being provided. CToolsLib is a collection of embedded target APIs/library to enable easy programmatic access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem capabilities of TI devices. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

<http://processors.wiki.ti.com/index.php/CToolsLib>

The previous link(s) connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

## 28.2 Debug Ports

### 28.2.1 IEEE1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: nTRST, TCK, TMS, TDI, and TDO
- A return clock (RTCK) due to the clocking requirements of the ARM968™ processor
- Two EMU [1:0] or five EMU [4:0] TI extensions, depending on the pin count (14 pins or 20 pins) in the JTAG header of the device.

Table 28-1 describes the IEEE1149.1 signals.

**Table 28-1. IEEE1149.1 Signals**

Pin Name	Internal Signal Name	Type (1)	Pull Type (3)	Function	Description
jtag_nrst	nTRST	I	PD	Test reset	When asserted (active low), causes all test and debug logic in the device to be reset along with the IEEE1149.1 interface
jtag_tck	TCK	I	PD	Test clock	This is the test clock used to drive an IEEE1149.1 test access port (TAP) state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the RTCK monitoring.
jtag_rtck	RTCK	O	N/A	Returned (synchronized) test clock	Depending on the DTC attached to the device, either the JTAG signals are clocked from RTCK or the RTCK is monitored by the DTC to the gate TCK.
jtag_tms_tmsc	TMS	I	PU	Test mode select	Directs the next state of the IEEE1149.1 TAP state-machine
jtag_tdi	TDI	I	PU	Test data input	Scans data input to the device
jtag_tdo	TDO	O	PU	Test data output	Scans data output by the device
dpm_emu0	EMU0	IO	PU	Emulation 0	Channel 0 trigger OR boot mode OR trace port
dpm_emu1	EMU1	IO	PU	Emulation 1	Channel 1 trigger OR boot mode OR trace port
dpm_emu2(2)	EMU2(2)	O	PD	Emulation 2	Trace port
dpm_emu3(2)	EMU3(2)	O	PD	Emulation 3	Trace port
dpm_emu4(2)	EMU4(2)	O	PD	Emulation 4	Trace port

(1) I = Input; O = Output

(2) 20-pin JTAG header only

(3) Internal pullup (PU)/pulldown (PD)

For information about the JTAG ID code value, see [Chapter 1, Introduction](#).

### 28.2.2 IEEE1149.7

Besides the standard (legacy) JTAG mode of operation, the target debug interface can also be switched to a compressed JTAG mode of operation, commonly referred to as IEEE1149.7 standard. An IEEE1149.7 adapter module runs a 2-pin communication protocol on top of an IEEE1149.1 JTAG TAP. The debug-IP logic serializes the IEEE1149.1 transactions, using a variety of compression formats, to reduce the number of pins needed to implement a JTAG debug port. The device implements only a subset of the IEEE1149.7 protocol (see [Table 28-3](#)).

---

**NOTE:** At power-on-reset (POR), the default debug interface mode is IEEE1149.1. See the IEEE1149.7 specification for the scan sequence required to switch modes.

---

The IEEE1149.7 communication protocol can switch between serial and parallel formats. The parallel format consists of the IEEE1149.1 signals, TCK, TMS, TDI, TDO, nTRST, and a RTCK return clock, if stalls are required. The serial format uses two signals, TCK and TMS. The values of the TMS, TDI, TDO, and RTCK signals are multiplexed on the bidirectional pin, jtag\_tms\_tmsc, by the Debug-IP logic. Each TCK of the DTC is serialized into a packet, which is transmitted to the IEEE1149.7 adapter, where it is converted back to parallel. The TDO and RTCK information are returned during the packet transmission.

---

**NOTE:** Only MScan, Oscan0, and Oscan4 formats can be used if the device requires stalls.

---

Table 28-2 describes the IEEE1149.7 signals.

**Table 28-2. IEEE1149.7 Signals**

Pin Name	Internal Signal Name	Type (1)	Pull Type (2)	Function	Description
jtag_tck	TCK	I	PD	Test clock	This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the TMS RDY field monitoring.
jtag_tms_tmsc	TMSC	I/O	PU	Test mode control and data scan	Compressed JTAG packet. The TMSC signal is driven only when the TCK signal is low. The signal level must be maintained by a keeper while the TCK signal is high.

(1) I = Input; O = Output

(2) Internal pullup (PU)/pulldown (PD)

Table 28-3 summarizes the IEEE1149.7 features subset supported by the device.

**Table 28-3. IEEE1149.7 Features Subset**

	IEEE1149.7 Feature	Device Support	Comment
<b>Configuration</b>	Class 4 TAP	✓	Supports 2-pin operation
	Class 5 TAP	–	No BDX or CDX channel
<b>Optional Components</b>	FRST	–	Functional reset (done via ICEPick)
	TRST	–	Test reset
	RDBK capability	✓	Read back of register data
	Aux Pin Functions	–	Reuse of TDI and TDO pins
	TCKWID	✓	Programmable TCK width

**Table 28-3. IEEE1149.7 Features Subset (continued)**

	IEEE1149.7 Feature	Device Support	Comment
<b>Scan Formats</b>	JScan0	✓	Parallel mode
	JScan1	✓	Parallel with firewall

### 28.2.3 Trace Port

On-chip debug and trace events can be exported to external equipment through the trace port in the device. The following exportable debug events and trace sources are supported:

- Debug events
  - Triggers. For more information about triggers, see [Section 28.4.2, Cross-Triggering](#).
- Trace sources
  - Processor trace: Cortex-A9 MPU trace supported by program trace macrocell (PTM) and trace port interface unit (TPIU) modules. For more information about processor trace, see [Section 28.7, Processor Trace](#).
  - System trace: Trace coming from various system instrumentation modules and supported by system trace module (STM). For more information about system trace, see [Section 28.8, System Instrumentation](#).

Note that not all debug and trace features can be supported concurrently due to limited amount of pins allocated to debug. Thus, a multiplexing among debug and trace sources is implemented. The configuration and the debug/trace source selection are done through the debug resource manager (DRM) module embedded in the debug subsystem.

[Table 28-4](#) describes the trace port signals.

**Table 28-4. Trace Port Signals**

Pin Name	Internal Signal Name	I/O	Pull Type <sup>(1)</sup>	Description
dpm_emu19	EMU19	O	PD	Debug resource manager pin 19
dpm_emu18	EMU18	O	PD	Debug resource manager pin 18
dpm_emu17	EMU17	O	PD	Debug resource manager pin 17
dpm_emu16	EMU16	O	PD	Debug resource manager pin 16
dpm_emu15	EMU15	O	PD	Debug resource manager pin 15
dpm_emu14	EMU14	O	PD	Debug resource manager pin 14

<sup>(1)</sup> Internal pullup (PU)/pulldown (PD)

**Table 28-4. Trace Port Signals (continued)**

Pin Name	Internal Signal Name	I/O	Pull Type <sup>(1)</sup>	Description
dpm_emu13	EMU13	O	PD	Debug resource manager pin 13
dpm_emu12	EMU12	O	PD	Debug resource manager pin 12
dpm_emu11	EMU11	O	PD	Debug resource manager pin 11
dpm_emu10	EMU10	O	PD	Debug resource manager pin 10
dpm_emu9	EMU9	O	PD	Debug resource manager pin 9
dpm_emu8	EMU8	O	PD	Debug resource manager pin 8
dpm_emu7	EMU7	O	PD	Debug resource manager pin 7
dpm_emu6	EMU6	O	PD	Debug resource manager pin 6
dpm_emu5	EMU5	O	PD	Debug resource manager pin 5
dpm_emu4	EMU4	O	PD	Debug resource manager pin 4
dpm_emu3	EMU3	O	PD	Debug resource manager pin 3
dpm_emu2	EMU2	O	PD	Debug resource manager pin 2
dpm_emu1	EMU1	I/O	PU	Debug resource manager pin 1
dpm_emu0	EMU0	I/O	PU	Debug resource manager pin 0

**NOTE:** The dpm\_emu[19:0] pins are shared with other functional (application) pins on the device boundary. To use the dpm\_emu[19:0] pins, user must program the device application pin manager (control module) appropriately. For more information, see [Chapter 18, Control Module](#).

For more information about DRM multiplexing and concurrent debug modes, see [Section 28.9, Concurrent Debug Modes](#).

### 28.2.4 End Product

For an end product phone, there are usually severe connectivity constraints and the standard debug ports may not be available at board level. This could make it difficult to trace and debug software.

To ease the process of tracing and debugging, a Narrow Interface for Debug and Test (NIDnT) concept defined by MIPI is used. NIDnT is based on IEEE1149.7 and STM interfaces and re-uses application interface pins. In the context of the device, the application interface that can serve as a NIDnT port is the MMC1 interface. To use the NIDnT port, the relevant MMC1 pins must be set to the appropriate MUX mode through control module.

[Table 28-5](#) shows the NIDnT port re-using MMC interface pins along with the corresponding MUX modes.

**Table 28-5. NIDnT Port Reusing MMC Interface Pins**

Module	Control Module Multiplexing		
	MUX0 (MMC)	MUX2 (STM)	MUX4 (IEEE1149.7)
Extension card (MMC)	sdmmc1_clk	dpm_emu19	–
	sdmmc1_cmd	uart1_rx	–
	sdmmc1_dat0	dpm_emu18	–
	sdmmc1_dat1	dpm_emu17	–
	sdmmc1_dat2	dpm_emu16	jtag_tms_tmssc
	sdmmc1_dat3	dpm_emu15	jtag_tck

---

**NOTE:** The nTRST signal must be driven high for the MMC1 interface to be used for IEEE1149.7 protocol.

---

**NOTE:** Uart1\_rx is an optional return channel. Depending on the trace receiver, the return channel is implemented by IEEE1149.1/IEEE1149.7.

---

For more information about how to configure the proper MUX mode, see [Chapter 18](#), *Control Module*.

For more information about the NIDnT concept, see *MIPI Alliance Test and Debug – NIDnT-Port* specification.

### **28.2.5 Trace Connector and Board Layout Considerations**

Because the device supports processor trace and system trace export, a 60-pin header in place of the traditional TI 14-pin, or a TI 20-pin emulation header may be required at board level. For more information about the trace connectors and board layout considerations for these high-speed signals, see *Emulation and Trace Headers* (TI literature number SPRU655).

## 28.3 Debugger Connection

### 28.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is the IEEE1149.7 adapter connected to the ICEPick module embedded in the debug subsystem.

---

**NOTE:** ICEPick version D (ICEPick-D) is used in the device.

---

System-on-chip (SoC) designs typically have multiple processors, each having a JTAG test access port (TAP) embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view, and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
  - Serially linking up to 16 TAP controllers
  - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management
  - Provides the power and clock states of each domain
  - Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
  - Applies system reset
  - Provides wait-in-reset (WIR) boot mode
  - Provides global and local WIR release
  - Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key has been properly programmed, ICEPick signals and subsystems emulation logics should be turned on.

For more information about ICEPick dynamic TAP insertion, see [Section 28.3.3, Dynamic TAP Insertion](#).

For more information about ICEPick power, reset, and clock management features, see [Section 28.5, Power, Reset, and Clock Management Debug Support](#).

### 28.3.2 Boot Modes

The initial configuration of ICEPick is determined by the level of the dpm\_emu0 and dpm\_emu1 pins upon POR release. At POR, dpm\_emu0 and dpm\_emu1 are automatically configured as inputs. The dpm\_emu0 and dpm\_emu1 pins are free once POR has been released.

[Table 28-6](#) summarizes the ICEPick boot modes.

**Table 28-6. ICEPick Boot Modes Upon POR**

dpm_emu1	dpm_emu0	TAPs in the TDI → TDO Path	Other Effects/Comments
0	0	None	Reserved (do not use)
0	1	None	Reserved (do not use)
1	0	ICEPick	TAP only + wait-in-reset mode

**Table 28-6. ICEPick Boot Modes Upon POR (continued)**

dpm_emu1	dpm_emu0	TAPs in the TDI → TDO Path	Other Effects/Comments
1	1	ICEPick	TAP only (default mode)

### 28.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This is the recommended boot mode.

### 28.3.2.2 Wait-In-Reset

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors may be released from reset (local), or all processors held in the reset state may be released at the same time (global).

## 28.3.3 Dynamic TAP Insertion

### 28.3.3.1 ICEPick Secondary TAPs

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

Figure 28-1 shows the TAPs in the ICEPick scan chain.

**Figure 28-1. ICEPick Scan Chain**

debug-002

**NOTE:** RES = Reserved/not used

CM3 = Cortex™-M3

DAP = Debug access port

Table 28-7 shows the secondary debug TAPs connected to the ICEPick scan chain along with the modules that can be accessed. The TAP number shows the position of the TAP in the scan chain.

## 28.4 Primary Debug Support

### 28.4.1 Processor Native Debug Support

#### 28.4.1.1 Cortex-A9 MPU

The dual Cortex-A9 processor supports the following native debug features:

- Halt mode and monitor mode debugging
- Six breakpoints and four watch points
- Asynchronous aborts
- Performance monitoring
- Cross-triggering: Allows stopping one CPU upon debug event (for example, breakpoint) detection in the other CPU

For more information about Cortex-A9 native debug support features, see the *Cortex-A9 Technical Reference Manual*.

#### 28.4.1.2 Cortex-M3 MPU

The Cortex-M3 processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watch point on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M3 native debug support features, see the *Cortex-M3 Technical Reference Manual*.

#### 28.4.1.3 DSP

The DSP core supports limited Advanced Event Triggering (AET), with the following capabilities:

- Hardware program breakpoints: Specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture
- Data watch points: Specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture

Known restrictions of this DSP core:

- No DSP processor trace support
- No real-time mode debug mode support
- Limited AET support, only two watch point units
- No HSRTDX support

#### 28.4.1.4 IVA-HD ARM968

The ARM968E-S processor supports the following native debug features through its EmbeddedICE-RT logic:

- Two hardware watch points/breakpoints
- Halt mode and monitor mode debugging
- Debug control and status registers
- Debug communications channel

For more information about ARM968 native debug support features, see the *ARM968E-S Technical Reference Manual*.

### 28.4.1.5 IVA-HD Hardware Accelerators

Hardware accelerators offer the following debug capabilities through their embedded SyncBox module:

- Manual halt: Halt occurs at the SyncBox task boundary, when requested by the debugger
- Single-step execution at SyncBox task level (from 1 to  $n$  macroblocks depending on the user software)
- Cross-triggering: Hardware accelerator can halt, after the execution of current SyncBox task, based on trigger event detection
- Global run

[Table 28-9](#) summarizes the debug capabilities of the hardware accelerator SyncBox.

**Table 28-9. Hardware Accelerator Debug Capability Options**

Feature	iME3	iPE3	MC3	CALC3	iLF3	ECD3
Core reset	-	-	-	-	-	-
Execution request	-	-	-	-	-	-
Trigger output	-	-	-	-	-	-
Trigger input	✓	✓	✓	✓	✓	✓
Number of trigger channels	1	1	1	1	1	1
Number of counters	0	0	0	0	0	0
Number of watch points	0	0	0	0	0	0
Number of hardware breakpoints	0	0	0	0	0	0

### 28.4.2 Cross-Triggering

The device supports a cross-triggering feature, which provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, a given *subsystem A* can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another *subsystem B* can be programmed to be sensitive to the trigger line input and to generate an action upon trigger detection.

Examples of debug events are: processor entering debug state, watch point match, PTM trigger, ETB full, ETB acquisition complete, etc.

Examples of debug actions are: debug request generation, restart (Cortex-A9 synchronous run), interrupt request generation, start/stop trace, etc.

Subsystems cross-triggering is consolidated at the device level by the XTRIGGER module, which is embedded in the debug subsystem.

---

**NOTE:** XTRIGGER is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

---

### 28.4.2.1 SOC Level Cross-Triggering

Table 28-10 summarizes the device cross-triggering capabilities.

**Table 28-10. XTRIGGER**

Subsystem	Module		Cortex-A9	PTM/E TB	Cortex-M3	Cortex-M3	Target Core	IVA3-C64x	IVA-HD ARM968	IVA-HD ARM968	HWA	PMI	CMI	OCP-WP	EMU0/ EMU1

**NOTE:** The following modules support only trigger inputs:

- IVA-HD hardware accelerators
- IVA-HD SMSET
- PMI
- CMI

### 28.4.3 Suspend

The device supports a suspend feature, which provides a way to stop a "closely coupled" hardware process running on a peripheral-IP when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (MPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and so coded using 1bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the corresponding peripheral-IP TRM chapter.

#### 28.4.3.1 Debug Aware Peripherals and Host Processors

Table 28-11 lists the mapping of the device processors to the suspend control input lines.

**Table 28-11. Debug Subsystem Suspend Input Lines**

Suspend Input Line	Host Processor

## 28.5 Power, Reset, and Clock Management Debug Support

The global power, reset, and clock management (PRCM) module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
  - Current power setting indicating whether the power domain is on or off
  - Loss of power detected since the software last checked the status
  - Current clock setting indicating whether the clock domain is on or off
  - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
  - Subsystem reset state
  - Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

ICEPick handles debug power management at the device level. In addition, the device implements a second level of debug power management through the DAP-PC module integrated in the Cortex-A9 MPU subsystem, which provides the same capabilities as ICEPick for the two Cortex-A9 CPUs. Each Cortex-A9 CPU core is in its own independent power domain, which DAP-PC manages. The hierarchical debug power-management approach provided by DAP-PC at the subsystem level and by ICEPick at the device level ensures a theoretically independent debug capability for each Cortex-A9 CPU core.

---

**NOTE:** The debugger must properly sequence global ICEPick and local DAP-PC commands:

- To force clocks/power:
    1. The debugger must first force it for the Cortex-A9 MPU subsystem at the ICEPick level.
    2. The debugger must then force it for a specific Cortex-A9 CPU at the DAP-PC level.
  - To release clocks/power:
    1. The debugger must first release it for a specific Cortex-A9 CPU at the DAP-PC level.
    2. The debugger must then release the Cortex-A9 MPU subsystem controls at the ICEPick level.
-

## 28.6 Performance Monitoring

### 28.6.1 Cortex-A9 MPU Subsystem Performance Monitoring

#### 28.6.1.1 Performance Monitoring Unit

The Cortex-A9 processor includes a performance monitoring unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU provides six counters to gather statistics about the operation of the processor and memory system. Each counter can count any of the events available in Cortex-A9. Upon counter overflow, PMU can generate an interrupt on its PMUIRQ output. This interrupt signal is mapped to the CTI TRIGIN[1] input and also routed to a Cortex-A9 MPU interrupt controller input (MA\_IRQ\_54 for Cortex-A9 CPU0 PMU; MA\_IRQ\_55 for Cortex-A9 CPU1 PMU).

The Cortex-A9 PMU outputs 52 events (PMUEVENT[51:0]) to PTM (see [Table 28-13](#)).

**Table 28-13. PMU Events**

PMU Event	Description
0	Software increment
1	Instruction fetch that causes a refill
2	Instruction fetch that causes a TLB refill
3	Data read or write operation that causes a refill
4	Data read or write operation that causes a cache access
5	Data read or write operation that causes a TLB refill
6	Data read architecturally executed
7	Data write architecturally executed
8,9	Number of instructions renamed: b00 = No instructions renamed b01 = One instruction renamed b10 = Two instructions renamed
10	Exception taken
11	Exception return architecturally executed
12	Change to context ID retired
13	Software change of PC
14	Immediate branch architecturally executed
15	Number of predictable function returns
16	Unaligned access architecturally executed
17	Branch mispredicted or not predicted
18	Branches or other change in program flow
19	Java byte code executed
20	Software Java byte code executed
21	Jazelle backward branches executed
22	Coherent line fill request that misses in other uniprocessors
23	Request for coherent line fill that hits in other uniprocessors
24	Instruction cache dependent stalls
25	Data cache dependent stalls
26	TLB miss dependent stalls
27	STREX passed
28	STREX failed
29	Data eviction
30	Issue does not dispatch any instruction.
31	Issue is empty.
32	Main execution unit pipe

**Table 28-13. PMU Events (continued)**

PMU Event	Description
33	Second execution unit pipe
34	Load/store pipe
35, 36	Number of floating-point instructions renamed: b00 = No floating-point instruction renamed b01 = One floating-point instruction renamed b10 = Two floating-point instructions renamed
37, 38	Number of NEON instructions renamed: b00 = No NEON instruction renamed b01 = One NEON instruction renamed b10 = Two NEON instructions renamed
39	PLD stall
40	Write stall
41	Instruction main TLB miss stall
42	Data main TLB miss stall
43	Instruction micro TLB miss stall
44	Data micro TLB miss stall
45	DMB stall
46	Integer core clock enabled
47	Data engine clock enabled
48	ISB
49	DSB
50	DMB
51	External interrupt

For more information about Cortex-A9 PMU, see the *ARM Cortex-A9 Technical Reference Manual*.

### 28.6.1.2 Snoop Control Unit

The individual CPU event monitors can be configured to gather statistics about the operation of the snoop control unit (SCU).

### 28.6.1.3 L2 Cache (PL310)

The Cortex-A9 MPU subsystem includes 512KB of L2 cache and uses PL310 as the L2 cache controller. The PL310 includes logic to support cache event monitoring.

[Table 28-14](#) summarizes the PL310 L2 cache events.

**Table 28-14. PL310 L2 Cache Events**

Event	Event Description
0	Eviction of a line from the L2 cache
1	Data read hit in the L2 cache
2	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
3	Data write hit in the L2 cache
4	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
5	Data write lookup to the L2 cache with Write-Through attribute. Subsequently results in a hit or miss.
6	Instruction read hit in the L2 cache
7	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
8	Prefetch line-fill sent to L3
9	Allocation into the L2 cache caused by a write (with Write-Allocate attribute) miss

The PL310 implements two 32-bit event counters. The PL310 can be configured to generate interrupts on error conditions or event counter overflow or increment. The PL310 interrupt is routed to MA\_IRQ\_0. When an interrupt occurs, software can look at the relevant interrupt status register to determine the source of the interrupt.

For more information about PL310, see the ARM *PrimeCell Level 2 Cache Controller (PL310) Technical Reference Manual*.

## 28.6.2 Cortex-M3 MPU Subsystem Performance Monitoring

### 28.6.2.1 Subsystem Counter Timer Module

The dual Cortex-M3 MPU subsystem includes a subsystem counter timer module (SCTM), which is embedded in shared cache and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- Forty-four shared cache events
- Four sleep/deep-sleep events from Cortex-M3 cores (one sleep and one deep sleep event per core)

[Table 28-15](#) describes the repartition of the Cortex-M3 SCTM counters.

**Table 28-15. Cortex-M3 SCTM Counters Repartition**

Counters	Features
0 – 1	Timer and event

### 28.6.3 DSP Subsystem Performance Monitoring

#### 28.6.3.1 Subsystem Counter Timer Module

The DSP subsystem includes an SCTM, which is embedded in the DSP megamodule and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect L1 and L2 events.

Table 28-15 describes the repartition of the DSP SCTM counters.

**Table 28-17. DSP SCTM Counters Repartition**

Counters	Features
0 – 1	Timer and event
2 – 7	Event (no chaining)

**28.6.3.2 L1 and L2 Events**

Table 28-18 summarizes the SCTM events for DSP subsystem.

**Table 28-18. SCTM Events for DSP Subsystem**

<b>Event</b>	<b>Event Description</b>
1	L1 Slave0 (program) tag hit
2	L1 Slave1 (data) tag hit
3	L1 Slave0 (program) tag miss
4	L1 Slave1 (data) tag miss
5	L1 Slave0 (program) fill buffer hit
6	L1 Slave1 (data) fill buffer hit
7	L1 Slave1 (data) write buffer access
8	L1 Allocation FIFO
9	L1 Slave0 (program) bank conflict
10	L1 Slave1 (data) bank conflict
11	L1 Slave0 (program) cached request
12	L1 Slave1 (data) cached request
13	L1 Slave0 (program) waiting for fill buffer
14	L1 Slave1 (data) waiting for fill buffer
15	L1 Slave0 (program) waiting for maintenance
16	L1 Slave1 (data) waiting for maintenance
17	L1 Eviction occurred
18	L1 Replacement occurred
19	L1 Allocation failed due to locked lines occurred
20	L2 tag hit
21	L2 tag miss
22	L2 fill buffer hit
23	L2 write buffer access
24	L2 allocation FIFO
25	L2 cached request
26	L2 waiting for fill buffer
27	L2 waiting for maintenance
28	L2 eviction occurred
29	L2 replacement occurred
30	L2 allocation failed due to locked lines occurred
31	Tied-off to 0

---

**NOTE:** Input index [0] is reserved for the free-running subsystem clock (used for total cycle profiling).

---

## 28.7 Processor Trace

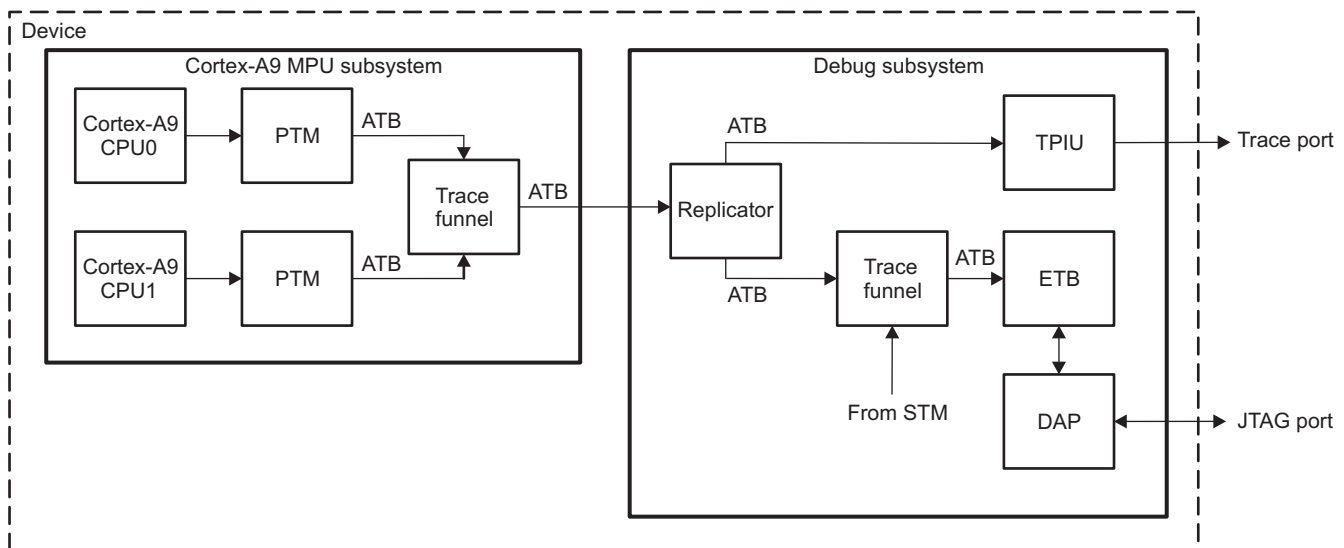

The device supports only Cortex-A9 processor trace. The main Cortex-A9 processor trace characteristics are:

- Program trace only (no data trace)
- Separate PTM for each Cortex-A9 CPU
- Trace can be:
  - Exported off-chip through TPIU in the debug subsystem (maximum number of trace data pins = 18)
  - Stored on-chip to ETB through CS-TF in the debug subsystem
- Trace can be optionally:
  - Cycle accurate useful for profiling sections of code
  - Interleaved dynamically between the two Cortex-A9 CPUs by a CS-TF embedded in the Cortex-A9 MPU subsystem

**NOTE:** Depending on use case, the device may not be able to interleave two cycle accurate traces without overflow (bandwidth restriction).

Figure 28-2 shows an overview of the processor trace flow.

**Figure 28-2. Processor Trace Flow**

debug-004

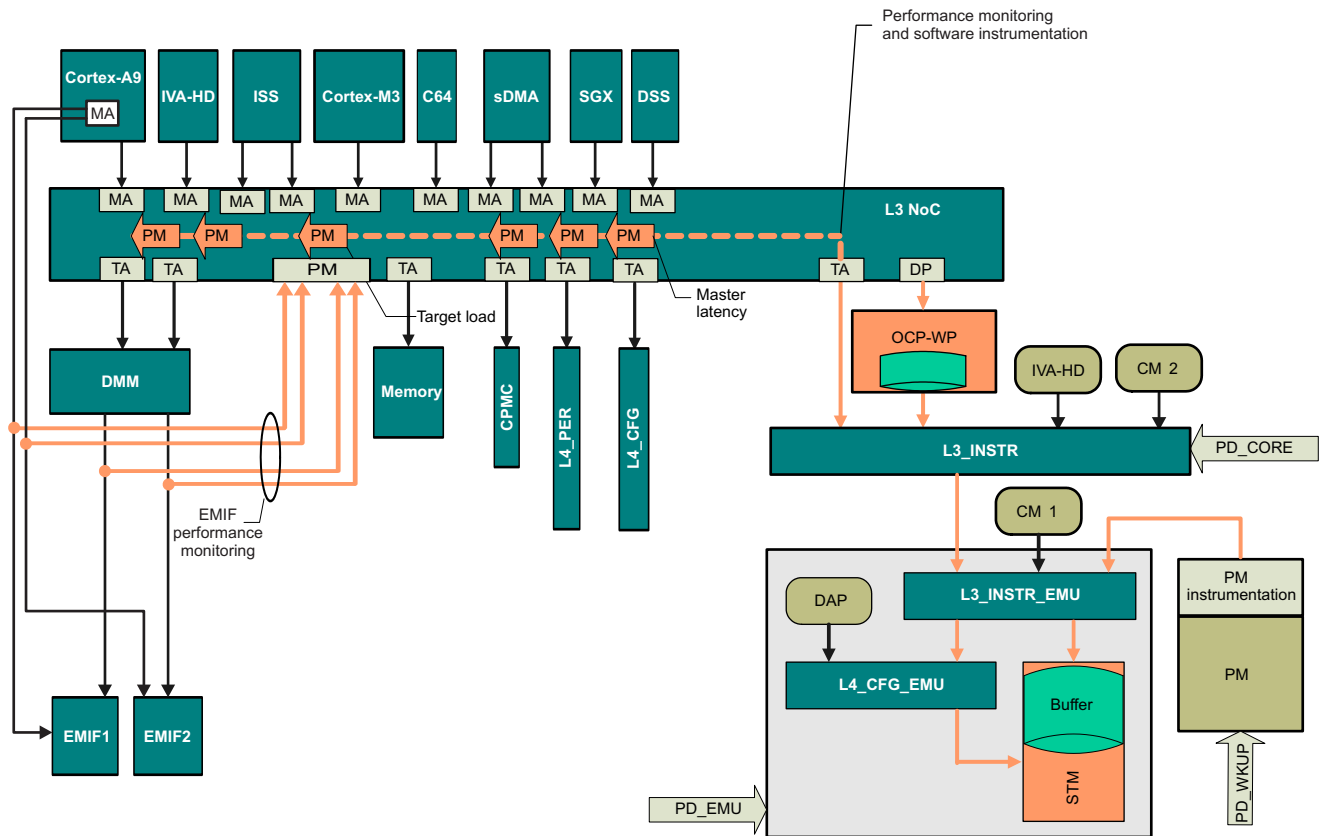

## 28.8 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace (see Section 28.8.2, *Software Instrumentation*)
- OCP target traffic monitoring (see Section 28.8.3, *OCP Watch-Point*)
- OCP target load and master latency monitoring (see Section 28.8.5, *NoC Statistics Collector*)
- HWA load monitoring (see Section 28.8.4, *IVA-HD Pipeline*)
- PM events trace (see Section 28.8.6, *PM Instrumentation [PMI]*)
- CM events trace (see Section 28.8.7, *CM Instrumentation [CMI]*)

Figure 28-3 is an overview of the device system instrumentation framework.

Figure 28-3. System Instrumentation Framework

debug-005

### 28.8.1 MIPI STM

MIPI-STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 1.0) with the following characteristics:
  - Highly optimized for software-generated traces
  - Automatic timestamping of messages
  - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
  - Software messages
  - Hardware instrumentation trace from hardware agents:
    - OCP-WP
    - PMI

- CMI
- SMSET
- L3 NoC statistics collectors
- Exports trace data to:
  - External trace receiver
  - On-chip ETB buffer
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver
- Dedicated 128 × 32-bit FIFO buffer

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

### 28.8.2 Software Instrumentation

The device provides support for real-time software trace through user-defined message writes to specific memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the software protocol implemented. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the on-going debugging task. The message structures in STP are optimized to provide an efficient transport for software data through the STM module.

The software masters are:

- Cortex-A9 MPU subsystem
- DAP (for testing purpose)
- DSP subsystem
- Dual Cortex-M3 MPU subsystem
- sDMA controller write port (SDMA\_WR)
- IVA-HD subsystem

Each software master has a master-ID assigned to it.

Software messages can be interleaved with other hardware messages.

Software messages are intrusive and use both processor cycles and memory.

### 28.8.3 OCP Watch-Point

The L3 interconnect provides five functional probes embedded and attached to the following L3 targets:

- GPMC
- L4-PER
- L4-CFG
- DMM1 (DMM target port 1)
- DMM2 (DMM target port 2)

The probes output are muxed together and then sent to the L3 interconnect debug port. A component called OCP-WP is used to collect data from functional probes and then transmit captured data to the STM module. The OCP-WP drives a Probe-ID signal to the L3 interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP-WP provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:

- Address range
- Initiator-ID (see [Table 28-20](#))
- Transaction type
- Transaction qualifier
- Generating a trigger upon watch-point match
- Starting and stopping OCP traffic monitoring upon:
  - WP address match
  - External trigger
- OCP-WP messages can be interleaved with software messages
- Programming from:
  - Debugger
  - Application

---

**NOTE:** The OCP-WP is restricted to monitor request flow.

---

[Table 28-19](#) summarizes the OCP targets that can be monitored by the OCP-WP and their respective probe-ID.

**Table 28-19. L3 Interconnect Functional Probe Mapping**

Probe-ID	L3 OCP Target
000	Reserved
001	GPMC
010	L4-PER
011	L4-CFG
100	DMM1 (DMM target port 1)
101	DMM2 (DMM target port 2)
110	Reserved
111	Reserved

[Table 28-20](#) summarizes the ConnID (Initiator-ID) mapping from a debug point of view.

**Table 28-20. ConnID Mapping (Debug View)**

ConnID	Initiator
0x0	Cortex-A9 MPU subsystem
0x4	CS-DAP
0x8	DSP

0x14	sDMA_RD
0x15	sDMA_WR
0x18	SGX
0x1C	Display subsystem
0x24	HSI
0x28	MMC1
0x29	MMC2

**Table 28-20. ConnID Mapping (Debug View) (continued)**

ConnID	Initiator
0x30	HSUSBHOST
0x31	HSUSBOTG
0x32	FSUSB
Other values	Reserved

**NOTE:** For information about ConnID values from a protection/error logging point of view, see [Section 13.2.3.2.3](#), Master NIU Identification, in [Chapter 13](#), Interconnect,

### 28.8.4 IVA-HD Pipeline

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding IVA-HD micro-task sequencing. This is supported through a SMSET module instantiated in the IVA-HD subsystem. The micro-task boundaries are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the MIPI-STM module.

The IVA-HD instrumentation scheme allows the user to understand micro-task dependencies, hardware accelerators load balancing, and potential bottlenecks. DMA transfer boundaries are reported as IVA-HD events. Software messages from ARM968 execution can be interleaved with IVA-HD events.

### 28.8.5 NoC Statistics Collector

The L3 interconnect supports a built-in performance monitoring feature by implementing a statistics collector (SC) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the MIPI-STM interface. Three SC instances are instantiated in the device:

- One statistics collector dedicated to SDRAM load monitoring – SC\_SDRAM (see [Section 28.8.5.1](#), *L3 Target Load Monitoring*, for more information)
- Two statistics collectors dedicated to master latency monitoring – SC\_LAT0 and SC\_LAT1 (see [Section 28.8.5.2](#), *L3 Master Latency Monitoring*, for more information)

Statistics collectors (SDRAM and LAT0/1) can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- % Link occupancy on the request link (for store transactions) during a sampling window
- % Link occupancy on the response link (for load transactions) during a sampling window
- % Arbitration conflict cycles on the request link
- % Initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16, 16–32, 32–128) each sampling window.
- Histogram of quality of service (QoS) metric for IVA-HD initiator (for example, low priority, high priority) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3 interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the events summarized in [Table 28-21](#).

**Table 28-21. Performance Monitoring Events Detection**

Event	Definition
NONE	No event selected
ANY	Any clock cycles
TRANSFER	Word has been accepted by the receiver.
WAIT	Transfer has been initiated but the transmitter currently has no data to send.
BUSY	Receiver applies flow control
PKT	Transfer of a new packet header
DATA	Transfer of a payload word
IDLES	No communication over the link
LATENCY	Debug bit detection

The probes can be configured to filter the traffic based on the criteria summarized in [Table 28-22](#).

**Table 28-22. Performance Filtering Options**

Probe Filtering Options	Comment
Master address	Mask and match
Slave address <sup>(1)</sup>	
UserInfo	
Read	
Write	
Error	
OCP address <sup>(2)</sup>	

<sup>(1)</sup> SC\_LAT0/1 only

<sup>(2)</sup> SC\_SDRAM only

[Table 28-23](#) specifies the slave address mapping (SC\_LAT0/1 only).

**Table 28-23. Statistics Collector Slave Address Mapping**

Slave	Address (hex)
HOST CLK1	0
DMM1 – NIU	1
DMM2 – NIU	2

L4_PER1 – NIU	10
L4_PER2 – NIU	11
L4_PER3 – NIU	12
Reserved	13
Reserved	14

**Table 28-23. Statistics Collector Slave Address Mapping (continued)**

Slave	Address (hex)
Reserved	15
Reserved	16
HOST CLK3	18
DEBUGSS – NIU	19

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

---

**NOTE:** Statistics collectors counter values are not accessible by application software.

---

[Table 28-24](#) summarizes the performance probe aggregation modes.

**Table 28-24. Aggregation Modes**

Aggregation Mode	Description
FILTER_HIT	The counter increments by 1 when the filter hits.
MIN_MAX_HIT	The counter increments by 1 when the filter hits and the selected event information is within range. - Payload length (bytes) - Pressure value - Request/response latency (clock cycles)
EVT_INFO	The selected event information is added to the counter value when the filter hits. Payload length (bytes) Pressure value Request/response latency (clock cycles)
AND_FILTER	The counter increments by 1 when all unit filters hit.
OR_FILTER	The counter increments by 1 when at least one unit filter hits.
SUM_REQ_EVT	The counter sums the events from any request port.
SUM_RSP_EVT	The counter sums the events from any response port.
SUM_ALL_EVT	The counter sums the events from any port.
EXT_EVT	The counter increments by 1 when selected external event input signal is sampled high.

### 28.8.5.1 L3 Target Load Monitoring

The L3 interconnect implements five performance monitoring probes on LPDDR2 memory channels. The traffic statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

SC\_SDRAM supports the following main features:

- Five probe inputs
  - Probe 0 – EMIF1 (DMM-EMIF1 128-bit port)
  - Probe 1 – EMIF2 (DMM-EMIF2 128-bit port)
  - Probe 2 – Memory Adapter 1 (MA-EMIF1 128-bit port)
  - Probe 3 – Memory Adapter 2 (MA-EMIF2 128-bit port)
  - Probe 4 – Reserved
- Eight 16-bit counters shared concurrently
  - Counter 0 with two filters
  - Counter 1 with one filter
  - Counter 2 with two filters
  - Counter 3 with one filter

- Counter 4 with one filter
- Counter 5 with one filter
- Counter 6 without any filter
- Counter 7 without any filter
- Simple (with one element) or complex (with several elements) filters available
- Filtering according to:
  - Initiator of traffic
  - Access priorities
  - OCP address
- No latency counter. Only bandwidth measurement on this collector
- 16-bit collecting window counter
- Dump Identifier is 0x0 (tie-off value)
- Dumps frames at L3 interconnect slave address 0x19 (debug subsystem)

Table 28-25 summarizes the SC\_SDRAM configuration.

**Table 28-25. SC\_SDRAM Configuration**

Counters	Min Max	Filter Elements	L3 Target				
			EMIF1	EMIF2	MA1	MA2	Reserved
Counter 0	Yes	2	EMIF1	EMIF2	MA1	MA2	Reserved
Counter 1	Yes	1	EMIF1	EMIF2	MA1	MA2	Reserved
Counter 2	Yes	2	EMIF1	EMIF2	MA1	MA2	Reserved
Counter 3	Yes	1	EMIF1	EMIF2	MA1	MA2	Reserved
Counter 4	Yes	1	EMIF1	EMIF2	MA1	MA2	Reserved
Counter 5	Yes	1	EMIF1	EMIF2	MA1	MA2	Reserved
Counter 6	Yes	No	No	No	MA1	MA2	Reserved
Counter 7	Yes	No	No	No	MA1	MA2	Reserved

### 28.8.5.2 L3 Master Latency Monitoring

The device L3 interconnect implements nine performance monitoring probes on the main L3 initiators:

- Cortex-A9 MPU subsystem
- DSP
- sDMA controller read port (SDMA\_RD)
- sDMA controller write port (SDMA\_WR)
- IVA-HD
- DSS
- ISS
- SGX
- Dual Cortex-M3 MPU subsystem

The master latency statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with on-going execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

### 28.8.5.2.1 SC\_LAT0 Configuration

SC\_LAT0 supports the following main features:

- Six probe inputs:
  - Probe 0: Cortex-A9 MPU subsystem
  - Probe 1: DSP subsystem
  - Probe 2: SDMA\_RD
  - Probe 3: SDMA\_WR
  - Probe 4: DSS
  - Probe 5: ISS
- Four 16-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter
  - Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 16-bit collecting window counter
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

Table 28-26 summarizes the SC\_LAT0 configuration.

**Table 28-26. SC\_LAT0 Configuration**

Counters	Min Max	Filter Elements	L3 Master					
			Cortex-A9 MPU subsystem	DSP	SDMA_RD	SDMA_WR	DSS	ISS
Counter 0	Yes	1	Cortex-A9 MPU subsystem	DSP	SDMA_RD	SDMA_WR	DSS	ISS
Counter 1	Yes	1	Cortex-A9 MPU subsystem	DSP	SDMA_RD	SDMA_WR	DSS	ISS
Counter 2	Yes	1	Cortex-A9 MPU subsystem	DSP	SDMA_RD	SDMA_WR	DSS	ISS
Counter 3	Yes	1	Cortex-A9 MPU subsystem	DSP	SDMA_RD	SDMA_WR	DSS	ISS

### 28.8.5.2.2 SC\_LAT1 Configuration

SC\_LAT1 supports the following main features:

- Five probe inputs:
  - Probe 0: IVA-HD
  - Probe 1: Cortex-A9 MPU subsystem
  - Probe 2: SDMA\_WR
  - Probe 3: SGX
  - Probe 4: Dual Cortex-M3 MPU subsystem
- Four 16-bit counters shared concurrently:
  - Counter 0 with one filter
  - Counter 1 with one filter
  - Counter 2 with one filter

- Counter 3 with one filter
- Filtering according to:
  - L3 target
  - Access priorities
- 10-bit counter for latency measurement
- 16-bit collecting window counter
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

Table 28-27 summarizes the SC\_LAT1 configuration.

**Table 28-27. SC\_LAT1 Configuration**

Counters	Min Max	Filter Elements	L3 Master				
			IVA-HD	Cortex-A9 MPU subsystem	SDMA_WR	SGX	Dual Cortex-M3 MPU subsystem
Counter 0	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	SDMA_WR	SGX	Dual Cortex-M3 MPU subsystem
Counter 1	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	SDMA_WR	SGX	Dual Cortex-M3 MPU subsystem
Counter 2	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	SDMA_WR	SGX	Dual Cortex-M3 MPU subsystem
Counter 3	Yes	1	IVA-HD	Cortex-A9 MPU subsystem	SDMA_WR	SGX	Dual Cortex-M3 MPU subsystem

### 28.8.6 PM Instrumentation (PMI)

The device takes advantage of the system trace infrastructure to provide visibility to the user about the major power management events. This is supported through a PMI module (PM profiler) instantiated in the PRM module. The PRM state changes are handled as generic events and encapsulated in STP hardware messages and exported through the MIPI-STM module. The nature of the PM events does not require accurate timestamping and thus, timestamping is handled at STM or trace receiver level.

The PM events are organized by class. Any PM state change from a specific class refreshes the entire instrumentation frame associated with that class. The STP message structure includes a PM event-ID indicating the class of the PM events.

The PM event classes supported are:

- Logic voltage domain OPP change
- Memory voltage domain OPP change
- Logic power domain state change
- Memory power domain state change

The PMI has a unique hardware master-ID assigned to it.

The PMI supports the possibility to report on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

Software events from the PM routines instrumentation can be interleaved with the PM hardware events. The user can take advantage of that feature to understand latencies for a specific power-management scenario or strategy.

### 28.8.7 CM Instrumentation (CMI)

The device instantiates two CMI modules (CM profilers), one in CM1 (CMI1), and one in CM2 (CMI2). The CMI1 and CMI2 modules are instantiations of the same debug-IP and can operate concurrently. Each of them has a separate unique hardware master-ID assigned to it.

The CM events profiling is similar to the PM instrumentation. Two exclusive instrumentation modes are supported:

- Clock activity:
  - Exposes to the user a snapshot of the state of all the clock domains derived from the same DPLL when CM detects a state change in the clock domain
  - Exposes to the user a snapshot of the DPLL settings when the CM signals a DPLL programming
- Module activity:
  - Exposes to the user periodically the active cycles count of the target modules
  - Exposes to the user periodically the active cycles count of the initiator modules

It provides visibility to the user about the state of the major clock domains along the application code execution. The STP message reports the effective state of the clock domain and therefore can highlight scenarios where a particular dependency is preventing the clock domain from being switched off.

The CM event classes supported are:

- Events capture mode – four classes:
  - Clock domain state
  - DPLL settings update
  - Clock frequency divider ratio
  - Clock source selection update
- Module activity collection mode – two classes:
  - Target module activity
  - Initiator module activity

When in events capture mode, the CMI supports the possibility of reporting on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

## 28.9 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin.

Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

[Table 28-28](#) summarizes the trace port configuration.

**Table 28-28. Trace Port Configuration**

Pin Name	Internal Signal Name	I/O	Trigger	JTAG 20-Pin Header	TPIU PTM (ARM Trace)		STM (System Trace)		
					16-Bit Mode	18-Bit Mode	Option 1	Option 2	Option 3
dpm_emu19	EMU19	O		EMU4	TRACEDATA[15]	TRACEDATA[17]		STM_CLK	
dpm_emu18	EMU18	O		EMU3	TRACEDATA[14]	TRACEDATA[16]		STM_DATA[0]	
dpm_emu17	EMU17	O		EMU2	TRACEDATA[13]	TRACEDATA[15]		STM_DATA[1]	
dpm_emu16	EMU16	O			TRACEDATA[12]	TRACEDATA[14]		STM_DATA[2]	
dpm_emu15	EMU15	O			TRACEDATA[11]	TRACEDATA[13]		STM_DATA[3]	
dpm_emu14	EMU14	O			TRACEDATA[10]	TRACEDATA[12]		UART1_RX	
dpm_emu13	EMU13	O			TRACEDATA[9]	TRACEDATA[11]			
dpm_emu12	EMU12	O			TRACEDATA[8]	TRACEDATA[10]			
dpm_emu11	EMU11	O			TRACEDATA[7]	TRACEDATA[9]			
dpm_emu10	EMU10	O			TRACEDATA[6]	TRACEDATA[8]			
dpm_emu9	EMU9	O			TRACEDATA[5]	TRACEDATA[7]			
dpm_emu8	EMU8	O			TRACEDATA[4]	TRACEDATA[6]			
dpm_emu7	EMU7	O			TRACEDATA[3]	TRACEDATA[5]			
dpm_emu6	EMU6	O			TRACEDATA[2]	TRACEDATA[4]			
dpm_emu5	EMU5	O			TRACEDATA[1]	TRACEDATA[3]			
dpm_emu4	EMU4	O			TRACEDATA[0]	TRACEDATA[2]	STM_DATA[3]		
dpm_emu3	EMU3	O			TRACECTL	TRACECTL	STM_DATA[2]		
dpm_emu2	EMU2	O			TRACECLK	TRACECLK	STM_CLK		
dpm_emu1	EMU1	I/O	Trigger 1	EMU1		TRACEDATA[1]	STM_DATA[1]		STM_CLK
dpm_emu0	EMU0	I/O	Trigger 0	EMU0		TRACEDATA[0]	STM_DATA[0]		STM_DATA[0]

**NOTE:** The configuration of the trace port must comply with [Table 28-28](#); otherwise, it will be ignored by DRM hardware. For example, if Trigger0 is programmed on EMU10 and Trigger1 is programmed on EMU11, this configuration will be ignored.

[Table 28-29](#) summarizes the concurrent debug and trace in the device.

**Table 28-29. Concurrent Debug and Trace**

Debug Use Case	Concurrent Debug Flows	Debug Pins	Trace Pins		
		Triggers	Data	Control	Clock

## 28.10 Memory Mapping

Table 28-30 summarizes the memory mapping of the debug modules.

**Table 28-30. Debug Modules Memory Mapping**

Memory Space	Module Name	Start Address (hex)	End Address (hex)	Size
L3_EMU	MIPI-STM (256 x 4K channels) (address space 0)	0x5400 0000	0x540F FFFF	1MB
	MIPI-STM (256 x 1K channels) (address space 1)	0x5410 0000	0x5413 FFFF	256KB
	Cortex-A9 CPU0 debug/PMU	0x5414 0000	0x5414 1FFF	8KB
	Cortex-A9 CPU1 debug/PMU	0x5414 2000	0x5414 3FFF	8KB
	CTI0 component	0x5414 8000	0x5414 8FFF	4KB
	CTI1 component	0x5414 9000	0x5414 9FFF	4KB
	PTM0 component	0x5414 C000	0x5414 CFFF	4KB
	PTM1 component	0x5414 D000	0x5414 DFFF	4KB
	CS-TF <sup>(1)</sup>	0x5415 8000	0x5415 8FFF	4KB
	DAP-PC	0x5415 9000	0x5415 9FFF	4KB
	DRM	0x5416 0000	0x5416 0FFF	4KB
	MIPI-STM	0x5416 1000	0x5416 1FFF	4KB
	CS-ETB	0x5416 2000	0x5416 2FFF	4KB
	CS-TPIU	0x5416 3000	0x5416 3FFF	4KB
	CS-TF <sup>(2)</sup>	0x5416 4000	0x5416 4FFF	4KB
L4_CFG	CMI1	0x4A00 4F00	0x4A00 4FFF	256B
	CMI2	0x4A00 9F00	0x4A00 9FFF	256B
	OCP-WP	0x4A10 2000	0x4A10 2FFF	4KB
L4_WKUP	PMI	0x4A30 7F00	0x4A30 7FFF	256B
IVA-HD configuration	ICECrusher-9 (iCONT1)	0x5A04 0000	0x5A04 07FF	2KB
	ICECrusher-9 (iCONT2)	0x5A04 0800	0x5A04 0FFF	2KB
	SMSET	0x5A04 1000	0x5A04 1FFF	4KB
L3 configuration	SC_SDRAM	0x4500 0400	0x4500 05FF	512B
	SC_LAT0	0x4500 0600	0x4500 07FF	512B
	SC_LAT1	0x4500 0800	0x4500 09FF	512B
DSP configuration	SCTM	0x01C3 0400	0x01C3 05FF	512B
Cortex-M3 MPU subsystem configuration	SCTM	0x5508 0400	0x5508 07FF	1KB
	ICECrusher-CS x 2 <sup>(3)</sup>	0xE004 2000	0xE004 2FFF	4KB

(1) Embedded in Cortex-A9 MPU subsystem

(2) Embedded in debug subsystem

(3) Private memory access per Cortex-M3 core

## Glossary

---

---

---

### 3

**3D**— Three Dimensional

**3G**— 3rd Generation of mobile communication systems

### A

**A/D**— Analog to Digital Converter

**ABB**— Adaptive Body Bias

**ABE**— Audio Back End

**ABEFW**— Audio Back End Firewall

**ACB**— ac–bias frequency

**ACBI**— ac–bias line transitions per interrupt

**ACE**— ASIC Compiler Environment.

**ACK**— Acknowledge

**ADC**— Analog–to–Digital Converter/Conversion.

**ADMA**— Audio DMA

**ADPLL**— All Digital Phase Locked Loop. A closed loop frequency control system whose function is based on the phase–sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).

**AE**— Audio Engine. The AESS own processor.

**AES**— Advanced Encryption Standard

**AESS**— Audio Engine Subsystem

**AEW**— Auto Exposure and Auto White Balance

**AF**— Auto Focus

**AFE**— Analog Front End

**AHB**— Advanced High-performance Bus

**ALE**— Address Latch Enable

**AMMU**— Attribute Memory Management Unit

**ANSI**— American National Standards Institute

**AP**— Address Protection

**APB**— Advanced Peripheral Bus

**APE**— Application Engine

**API**— Application Programming Interface

**AR**— Automatic Reload

**ARGB**— Alpha Red Green Blue

**ARM**— Advanced RISC Machine

**ASCII**— American Standard Code for Information Interchange

**ASIC**— Application-Specific Integrated Circuit. A chip built for a particular application. In the context of this document, this refers to the FPGA that resides on the EVM board.

**ASP**— Application-Specific Peripheral

**ATA**— Interface standard for the connection of storage devices

**ATB**— AMBA Advanced Trace Bus

**ATC**— Audio Traffic Controller

**AVDAC**— Audio-Video DAC

**AVS**— Adaptive Voltage Scaling

**AWB**— Auto White Balance

**B**

**B**— Byte, 8 bits

**BAYER**— Bayer Filter mosaic. A color filter array (CFA) for arranging RGB color filters on a square grid of photosensors.

**BB**— Bus Busy

**BCD**— Binary-Coded Decimal.

**BCH**— Bose-Chaudhuri-Hocquenghem

**BE**— Big Endian.

**BGA**— Ball Grid Array

**BGAP**— Band Gap

**BIOS**— Built-In Operating System

**BIST**— Built-In Self-Test

**BL**— Buffer Logic

**BOF**— Beginning of Frame

**BPP**— Bits Per Pixel

**BS**— Block Synchronization

**BSC**— Boundary Scan Chain

**BSMEM**— Bit Stream Memory

**BTA**— Bus Turn Around

**BTE**— Burst Translation Engine

**BW**— Band Width

**Bluetooth**— A short-range radio technology aimed at simplifying communications among network devices and between devices and the Internet. It also aims to simplify data synchronization between network devices and other computers.

## C

**CABAC**— Context-Adaptive Binary Arithmetic Coding

**CALC3**— Transform and Quantization Calculation Engine

**CAS**— Column Address Strobe

**CAVLC**— Context-Adaptive Variable Length Coder

**CB**— Copy Back

**CBP**— Coded Block Pattern

**CBUFF**— Circular Buffer

**CCCR**— Card Common Control Registers (SDIO)

**CCP**— Compact Camera Port

**CDP**— Coprocessor Data Operation

**CDR**— Clock Data Recovery

**CE**— Chip Enable

**CEA-861-D**— HDMI 1.3 video standard. It defines the video timing requirements, discovery structures, and data transfer structure.

**CEC**— Consumer Electronics Control

**CFA**— Color Filter Array

**CH**— Configuration Header. To use different settings than ROM Code defaults, that is, clock frequencies, SDRAM/DDRAM settings, GPMC settings if the customer wants.

**CID**— Card Identification Number

**CIR**— Consumer Infra Red

**CLE**— Command Latch Enable

**CLK**— Clock

**CLUT**— Color Look-Up Table

**CM**— Clock Management

**CMEM**— Coefficient Memory

**CMOS**— Complimentary Metal Oxide Semiconductor

**CODEC**— Coder/Decoder or Compression/Decompression. A device that codes in one direction of transmission and decodes in another direction of transmission.

**CP15**— Coprocessor 15. This coprocessor controls the operation and configuration of the TI925T.

**CPR**— Clock, Power, Reset

**CPU**— Central Processing Unit.

- CRC**— Cyclic Redundancy Check
- CS**— Chip-Select
- CS-ETB**— CoreSight Embedded Trace Buffer
- CS-ETM**— CoreSight Embedded Trace Macrocell
- CS-TPIU**— CoreSight Trace Port Interface Unit
- CSI**— Camera Serial Interface
- CSW**— Control Space Width
- CSWR**— Closed switch retention
- CTM**— Counter-Timer Module
- CTRL**— Control
- CTS**— Clear to Send
- CVBS**— Composite Video Broadcast Signal
- ConnID**— Connection Identifier. An Initiator Module Identifier. A ConnID is transmitted in-band with the request and is used for protection and error logging mechanism.

## D

- D2D**— Die-to-Die
- DAC**— Digital to Analog Converter
- DBB**— Digital Baseband
- DBI**— Display Buffer Interface
- DCD**— Data Carrier Detect
- DCO**— Digitally Controlled Oscillator
- DCS**— Display Command Set
- DCT**— Discrete Cosine Transform.
- DDC**— Display Data Channel
- DDMA**— DSP Subsystem Direct Memory Access module
- DDR**— Double Data Rate
- DE**— Data Enable
- DFF**— Digital Flip-Flop
- DFT**— Design For Test
- DI**— Data In
- DISPC**— Display Controller
- DL**— Data Length
- DLB**— Data Loopback.
- DLL**— Delay-Locked Loop
- DMA**— Direct Memory Access.

**DMC**— Data Memory Controller

**DMEM**— Data Memory

**DMIC**— Digital Microphone Controller

**DMM**— Dynamic Memory Management

**DNL**— Differential nonlinearity. It describes the deviation between two analog values corresponding to adjacent input digital values for a DAC.

**DO**— Data Out

**DPC**— Defect Pixel Correction

**DPCM**— Differential Pulse Code Modulation

**DPI**— Display Parallel Interface

**DPLL**— Digital Phase-Locked Loop. Digital implementation of PLL.

**DPS**— Digital Power Switching

**DRD**— Dual-Role Device (a type of OTG USB device)

**DRDY**— Data Ready

**DRM**— Digital Rights Management

**DRP**— Digital Radio Processor

**DSI**— Display Serial Interface

**DSP**— Digital Signal Processor.

**DSR**— Data Set Ready

**DSS**— Display Sub-System. Also DISS

**DT**— Data Type

**DTBC**— Data Buffer Controller

**DTCM**— Data Tightly Coupled Memory

**DTR**— Data Transmit Ready

**DVFS**— Dynamic Voltage and Frequency Scaling

**DVI**— Digital Video Interface

**E**

**EA**— Enumeration Address

**EAV**— End of Active Video

**ECC**— Error Checking and Correction. Also Error Correction Code.

**ECD3**— Entropy Coder/Decoder

**ED**— Endpoint Descriptor

**EFUSE**— Electrical Fuse. A one-time programmable memory location usually set at the factory

**EHCI**— Enhanced Host Controller Interface

**EMC**— External Memory Controller

**EMI**— Electromagnetic interference  
**EMIF**— External Memory Interface  
**EOB**— End of Block  
**EOF**— End of Frame  
**EOL**— End of Line  
**EOT**— End of Transfer  
**EPM**— Emulation Pin Manager  
**ES**— Erase Status  
**ETB**— Embedded Trace Bus  
**ETM**— Embedded Trace Macrocell

**F**

**FAT**— File Allocation Table  
**FCLK**— Functional Clock  
**FCS**— Frame Check Sequence  
**FD**— Face Detect  
**FE**— Framing Error.  
**FEC**— Frame End Code  
**FF**— Flip-Flop  
**FIFO**— First In First Out.  
**FIQ**— Fast Interrupt Request. See ISR.  
**FIR**— Fast Infrared  
**FM**— Frequency Modulate  
**FPS**— Frame per Second  
**FROM**— eFuse ROM  
**FS**— Full-Speed  
**FSC**— Frame Start Code. Also Frame Start Count.  
**FSM**— Finite State Machine.  
**FSR**— Fault Status Register  
**FV**— Focus Value  
**FW**— Firewall

**G**

**GBC**— Green Balance Correction  
**GDP**— Generic Dot Product  
**GHB**— Global History Buffer

**GPIO**— Genreal Purpose Input Output  
**GPMC**— General Purpose Memory Controller

## H

**H.263**— Video Codec Standart  
**H.264**— Video Codec Standart  
**H/W**— Hardware  
**HAL**— Hardware Abstraction Layer  
**HBP**— Horizontal Back Porch  
**HC**— Host Controller  
**HD**— High Definition  
**HDCP**— High-bandwidth Digital Content Protection  
**HDMI**— High-Definition Multimedia Interface  
**HDQ**— Single-wire communication interface  
**HDTV**— High-Definition Television  
**HFP**— Horizontal Front Porch  
**HLOS**— High-Level Operating System  
**HNP**— Host Negotiation Protocol (OTG feature)  
**HPF**— High-Pass Filter  
**HPI**— Host Port Interface  
**HS**— High-Speed  
**HSE**— Horizontal Sync End  
**HSI**— High Speed Synchronous Serial Interface  
**HSS**— Horizontal Sync Start  
**HSSCLL**— High-Speed Serial Control Channel  
**HSW**— Horizontal Synchronization Pulse Width  
**HSYNC**— Horizontal Synchronization.  
**HW**— Hardware  
**HWA**— Hardware Accelerators.  
**HWOBS**— Hardware Observability  
**HWSEQ**— Hardware Sequencer

## I

**I/F**— Interface  
**I/O**— Input/Output  
**I2C**— Inter-Integrated Circuit.

- I2S**— Inter-IC Sound.
- IA**— Identifier Address
- ICE**— In-Circuit Emulation
- ICEPICK**— Generic TAP for emulation control
- ICLK**— Interface Clock
- ICONT**— Imaging Controller
- ICR**— Intersystem Communication Registers
- ID**— Identification
- IDCT**— Inverse Discrete Cosine Transform. See DCT.
- ILF3**— Improved Loop Filter engine
- IM**— Initiator Module. A module is an initiator whenever it is able to initiate read and write requests to the chip interconnect (typically: processors , DMA...).
- IME3**— Improved Motion Estimation engine
- IMX**— Image Extension coprocessor
- INL**— Integral Nonlinearity. It describes the maximum deviation between the ideal output of a DAC and the actual output level.
- INT**— Interrupt .
- INTC**— Interrupt Controller
- IP**— Intellectual Property
- IPC**— Interprocessor Communication. (also referred to as mailbox on occasion)
- IPE3**— Intra Prediction Estimation engine
- IPIPE**— Image Pipe
- IPIPEIF**— Image Pipe Interface
- IQ**— Inverse Quantization
- IR**— Incremental Redundancy Buffer
- IRQ**— Interrupt Request.
- ISA**— Instruction Set Architecture
- ISIF**— Image Sensor Interface
- ISP**— Image Signal Processor
- ISR**— Interrupt Service Routine.
- ISS**— Image SubSystem
- IST**— Interrupt Service Thread.
- ITCM**— Instruction Tightly Coupled Memory
- IV**— Initialization Vector
- IVA**— Image and Video Accelerator

**IVA-HD**— High Definition Image and Video Accelerator

**IrDA**— Infrared Data Association.

## J

**JEDEC**— Joint Electronic Devices Engineering Council

**JPEG**— Joint Photographics Experts Group

**JTAG**— Joint Test Action Group.

## K

**KB**— Kilobyte, 1024 B

**KBD**— Keyboard

**Kbps**— Kilobits per second

## L

**L1**— Level 1 cache/memory

**L2**— Level 2 cache/memory

**L3**— First level of interconnect

**L4**— Second level of interconnect

**LA**— Logical Address

**LAN**— Local Area Network

**LC**— Logical Channel

**LCD**— Liquid Crystal Display.

**LCM**— Logical Channel to Memory

**LCh**— Logical DMA Channel. Also LCH

**LDC**— Load (from memory) to Coprocessor

**LDC2**— Lens Distortion Correction

**LDM**— Load Multiple

**LDO**— Low Dropout

**LE**— Little Endian.

**LEC**— Line End Code

**LED**— Light Emitting Diode.

**LF**— Loop Filter

**LFB**— Line-Fill-Buffer

**LFN**— Long File Name

**LH**— Local Host

**LINK**— Link Layer Device

**LLP**— Low-Level Protocol

**LP**— Low-Power, operation mode for PHY  
**LPCM**— Linear Pulse Code Modulation  
**LPDDR**— Low Power Double Data Rate  
**LPF**— Loop Filter  
**LPM**— Low-Power Mode  
**LPP**— Lines Per Panel  
**LRB**— Line-Read-Buffer  
**LS**— Low-Speed  
**LSB**— Least Significant Bit  
**LSC**— Line Start Code  
**LSR**— Linear Shift Register  
**LSW**— Least Significant Word  
**LUT**— Look-up Table

**M**

**M2**— Micro Memory  
**MAC**— Message Authentication Code  
**MB**— Megabyte, 1024 KB  
**MBAFF**— MB-Level Adaptive Frame/Field  
**MBR**— Master Boot Record  
**MC3**— Motion Compensation Engine  
**MCSPi**— Multichannel Serial Port Interface  
**MCU**— Microcontroller Unit. Refers to the MPU.  
**ME**— Motion Estimation  
**MEMIF**— Memory Interface  
**MIF**— Memory InterFace  
**MIPI**— Mobile Industry Processor Interface  
**MIR**— Medium Infrared  
**MJPEG**— Motion JPEG  
**MMC**— Multimedia Card  
**MMC/SD**— Multimedia Card/SD  
**MMU**— Memory Management Unit.  
**MP3**— MPEG Layer 3.  
**MPEG**— Motion Pictures Expert Group.  
**MPEG1**— The first MPEG compression scheme specification.

**MPU**— Microprocessor Unit.  
**MS**— Memory Stick  
**MSB**— Most Significant Bit  
**MSGIF**— Message Interface  
**Mb**— Megabit  
**Mbps**— Mega bits per second  
**McBSP**— Multichannel Buffered Serial Port.  
**Modem**— Modulator Demodulator

**N**

**N/A**— Not Applicable  
**NAC**— Network Access Control  
**NAK**— Not Acknowledged  
**NAND**— NAND Flash memory.  
**NC**— Not Connected  
**NIU**— Network Interface Unit  
**NMI**— Nonmaskable Interrupt. An interrupt that can be neither masked nor disabled.  
**NOP**— No OPeration (DSP/CPU instruction)  
**NOR**— A type of flash memory  
**NRZI**— Non-Return-to-Zero Inverted  
**NSF**— Noise Filter  
**NTSC**— National Television System Committee. Television broadcast system.  
**NVB**— Number of Valid Bytes  
**NVIC**— Nested Vectored Interrupt Controller  
**NVM**— Non-volatile Memory

**O**

**OCM**— On-chip Memory  
**OCMC**— On-chip Memory Controller  
**OCP**— Open-Core Protocol  
**OCPI**— Open-Core Protocol Interface  
**OE**— Output Enable  
**OHCI**— Open Host Controller Interface. This is an industry standard USB Host Controller Interface.  
**OMAP**— Open Multimedia Application Platform  
**ON2**— Video Codec Standart  
**OPP**— Operating Performance Point

- OS**— Operating System
- OSI**— (OSI model) Open Systems Interconnection Basic Reference Model
- OTG**— On-The-Go (USB 2.0 specification)

**P**

- PA**— Program Address
- PBIAS**— PMOS Bias transistor to provide the bias voltage to extended drain IOs
- PC**— Program Counter
- PCB**— Printed Circuit Board
- PCI**— Peripheral Component Interconnect.
- PCLK**— Pixel Clock
- PCM**— Pulse Code Modulation.
- PD**— Program Data
- PDA**— Personal Digital Assistant
- PDC**— Power-down Controller
- PDM**— Pulse Density Modulation
- PDU**— Protocol Data Unit
- PE**— Parity Error
- PF**— Packet Footer
- PFPW**— Prefetch and Prewrite posting engine
- PH**— Packet Header
- PHY**— Physical Layer Device
- PI**— Pixel Interpolation
- PID**— Protocol Identifier. The PID register is used in Windows CE mode only.
- PLL**— Phase-Locked Loop.
- PM**— Programming Model
- PMC**— Program Memory Controller
- PMEM**— Program Memory
- PMP**— Power Management Port
- POR**— Power-On Reset
- PPA**— Primary Protected Application.
- PPC**— Palm-size PC
- PPI**— Physical Layer Protocol Interface
- PPL**— Pixels per Line
- PRCM**— Power, Reset, Clock Management module

- PRM**— Power and Reset manager
- PS**— Packet Start
- PSC**— Prescaler Counter
- PSS**— Program Suspend Status
- PT**— Packet Type
- PTM**— Program Trace Macrocell
- PTV**— Prescale Clock Timer Value. Sets the value of the divisor used in scaling the clock.
- PU/PD**— Pull-Up / Pull-Down
- PWL**— Pulse Width Light (modulator). A 4096-bit randomsequence generator that provides control of the LCD backlighting and keypad.
- PWM**— Pulse Width Modulation
- PWR**— Power

**Q**

- QIQ**— Quantization and Inverse Quantization
- QMEM**— Quantizer Memory
- QMR**— Quantizer Matrix
- QVGA**— Quarter Video Graphics Array. One-fourth the resolution of VGA.

**R**

- R/W**— Read/Write. Also RW.
- R5**— Release 5 of 3GPP specifications on IMS and HSDPA standards
- R6**— Release 6 of 3GPP specifications on Wireless LAN networks, HSUPA, MBMS and enhancements to IMS standards
- RAM**— Random Access Memory. A memory element that can be written to, as well as read.
- RCA**— Relative Card Address
- RDR**— Receive Data Register
- RE**— Read Enable
- REQ**— Request
- RF**— Radio Frequency
- RFB**— Remote Frame Buffer
- RFBI**— Remote Frame Buffer Interface
- RFF**— Retention Flip-Flop
- RGB**— Red Green Blue
- RGBA**— Red Green Blue Alpha
- RI**— Ring Indicator
- RM**— Reed-Muller code

**RO**— Read Only

**ROM**— Read Only Memory. A semiconductor storage element containing permanent data that cannot be changed.

**RST**— Reset

**RT**— Real-Time

**RTA**— Retention Till Access

**RTC**— Real-Time Clock. A clock that keeps track of the time even when the device is turned off.

**RTL**— Register Transfer Level

**RTOS**— Real-Time Operating System

**RTS**— Request to Send

**RVLC**— Reversible Variable Length Coder

**RX**— Receive/Receiver

**RXD**— Receive Data

## S

**S/PDIF**— Sony/Philips Digital Interface

**S/W**— Software

**SAM**— Signal Amplitude Modulation

**SAR**— Save and Restore. Hardware context saving for power saving.

**SAV**— Start of Active Video

**SB**— Silicon Backplane (Trade Mark)

**SBC**— Stream Buffer Controller

**SCCB**— Serial Camera Control Interface. 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.

**SCL**— Serial Clock. Programmable serial clock used in the I2C interface. Also SCLK.

**SCM**— System Control Module

**SCP**— Serial Configuration Port

**SCR**— SDIO Configuration Registers

**SCRM**— System Clock and Reset Manager

**SCTM**— System Counter Timer Module

**SCU**— Snoop Control Unit

**SD**— SD card. A non-volatile memory card.

**SDA**— Serial Data. Serial data bus in the I2C interface.

**SDHC**— SD High Capacity card

**SDIO**— SD Input/Output

**SDMA**— System Direct Memory Access module

- SDP**— Software Development Platform
- SDR**— Single Data Rate
- SDRAM**— Synchronous Dynamic Random Access Memory
- SDRC**— SDRAM Controller.
- SE**— Safe Environment. Execution environment inside a device, which is protected against tampering
- SFL**— Subframe Length
- SGX**— Acronym for Graphics Accelerator
- SIM**— Subscriber Identity Module
- SIMCOP**— Still image coprocessor
- SIMD**— Single Instruction-Stream, Multiple Data-Stream
- SIR**— Slow Infrared
- SL2**— Shared Level 2 (memory/interface)
- SLM**— Static Leakage Management
- SLVS**— Scalable Low Voltage Signaling
- SMC**— Shared Message Channel
- SMEM**— Sample Memory
- SMI**— Safe Monitor Interrupt
- SMP**— Symmetric Multiprocessor Platform
- SMPS**— Switch Mode Power Supply
- SMSET**— Software Message and System Event Trace module
- SNR**— Signal-to-Noise Ratio
- SOC**— System-On-a-Chip
- SOF**— Start Of Frame
- SP**— Serial Port or Small Page
- SPI**— Serial Port Interface. A signaling protocol for exchanging serial data.
- SR**— SmartReflex
- SRAM**— Static Random Access Memory
- SRC**— Sample Rate Conversion
- SRG**— Sample Rate Generator
- SRP**— Session Request Protocol (OTG feature)
- SS**— Subsystem
- SSC**— Spread Spectrum Clocking
- SSI**— Serial Synchronous Interface
- ST**— Start Timer

- STC**— Store from Coprocessor (to memory) or System Time Clock, which is the master clock in an MPEG-2 encoder or decoder system.
- STM**— Synchronous Transfer Mode or Store Multiple.
- STN**— Super-Twist Nematic. A technique for improving LCD display screens by twisting light rays.
- SW**— Software
- SWI**— Software Interrupt
- SXGA**— Super eXtended Graphics Array
- SYSC**— System Control Module
- SmartReflex**— Dynamic voltage sensing module that generates the voltage error signal proportional to the difference in desired voltage and the current voltage

**T**

- TA**— Target Agent
- TAP**— Test Access Port
- TC**— Traffic Controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.
- TCK**— Test Clock
- TCM**— Tightly Coupled Memory
- TD**— Transfer Descriptor
- TDI**— Test Data Input
- TDM**— Time Division Multiplex/Multiplexing
- TDO**— Test Data Output
- TFT**— Thin Film Transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.
- TI**— Texas Instruments
- TL**— Transmission Line
- TLB**— Translation Lookaside Buffer. A cache that contains entries for virtual-to-physical address translation and access permission checking.
- TLL**— Transceiver Less Link. This is logic which allows the user to connect two USB transceiver interfaces together directly without the use of differential transceivers.
- TM**— Target Module. A target module cannot generate read/write requests to the chip interconnects, but respond to these requests. However it may generate interrupts or DMA request to the system (typically: peripherals, memory controllers).
- TMDS**— Transition Minimized Differential Signaling. A technology for transmitting high-speed serial data and is used by the DVI and HDMI video interfaces.
- TMS**— Test Mode Select
- TOC**— Table of Contents
- TP**— Tiny Page
- TRM**— Technical Reference Manual

- TRST**— Test Reset
- TRX**— USB Transceiver. The USB analog driver/receiver.
- TSHUT**— Temperature Shutdown.
- TTB**— Translation Table Base. It points to the base of a table in physical memory that contains section and page table descriptors.
- TTH**— Translation Table Hierarchy
- TTL**— Transistor Transistor Logic
- TWL**— Table Walking Logic
- TX**— Transmit/Transmitter

## U

- UART**— Universal Asynchronous Receiver/Transmitter. Another name for the asynchronous serial port.
- UE**— Unrecoverable Error
- UHS**— Definition of SD cards with higher frequency
- ULPI**— UTMI+ Low Pin Interface (12-pin interface standard for connecting USB core logic to a USB transceiver)
- ULPM**— Ultralow-Power Mode
- ULPS**— Ultralow-Power State
- UMC**— Unified Memory Controller
- USB**— Universal Serial Bus. An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.
- USSE**— Universal Scalable Shader Engine
- UTMI**— USB 2.0 Transceiver Macrocell Interface

## V

- VA**— Volt-Amps. A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.
- VBP**— Vertical Back Porch
- VC**— Virtual Channel
- VC-1**— Video Codec Standart
- VDMA**— Video Direct Memory Access module
- VENC**— Video Encoder
- VESA**— Video Electronics Standards Association
- VFP**— Vertical Front Porch
- VGA**— Video Graphics Array. An industry standard for video cards.
- VLC**— Variable Length Decoder
- VLCD**— Variable Length Coding and Decoding coprocessor

**VLCDJ**— Variable-Length Coder/Decoder for JPEG

**VLD**— Variable Length Coder

**VLIW**— Very Long Instruction Word

**VMODE**— Bi-level voltage control interface

**VP**— Video Port

**VRFB**— Virtual Rotation Fixed Buffer

**VS**— Vertical Synchronization

**VSE**— Vertical Sync End

**VSS**— Vertical Sync Start

**VSW**— Vertical Synchronization Pulse Width

**VSYNC**— Vertical Synchronization. A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode). Also VS.

## W

**WB**— Write Buffer

**WC**— Word Count

**WD**— Watchdog. A timer that requires the user program or OS periodically write to the count register before the counter underflows.

**WDT**— Watchdog Timer

**WE**— Write Enable

**WFI**— Wait For Interrupt

**WNP**— Write Non-Posted

**WP**— Write Protect

**WSS**— Wide-Screen Signaling

**WT**— Write Through

**WTBU**— Wireless Terminal Business Unit

**WUGEN**— Wake-Up Generator

**Word16**— 16 bits word

## X

**XGA**— eXtended Graphics Array. Also XVGA.

**XIP**— eXecution In Place

## Y

**YUV**— Luminance-Bandwidth-Chrominance

## e

**eMMC**— Embedded Multimedia Card

**eSD**— Embedded SD

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.

### Products

Audio	<a href="http://www.ti.com/audio">www.ti.com/audio</a>
Amplifiers	<a href="http://amplifier.ti.com">amplifier.ti.com</a>
Data Converters	<a href="http://dataconverter.ti.com">dataconverter.ti.com</a>
DLP® Products	<a href="http://www.dlp.com">www.dlp.com</a>
DSP	<a href="http://dsp.ti.com">dsp.ti.com</a>
