Bits	Field Name	Description	Type	Reset
31:26	RESERVED		R	0x00
25	CLKACTIVITY_PER_ABE_24M_FCLK	This field indicates the state of the PER_ABE_24M_FCLK clock in the domain. [warm reset insensitive]  Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
24	RESERVED		R	0
23	RESERVED		R	0
22	CLKACTIVITY_PER_MCBSP4_FCLK	This field indicates the state of the PER_MCBSP4_FCLK clock in the domain. [warm reset insensitive]  Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
21:20	RESERVED		R	0

Bits	Field Name	Description	Type	Reset
19	CLKACTIVITY_PER_96M_FCLK	This field indicates the state of the PER_96M_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
18	CLKACTIVITY_PER_48M_FCLK	This field indicates the state of the PER_48M_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
17	CLKACTIVITY_PER_32K_FCLK	This field indicates the state of the PER_32K_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
16	CLKACTIVITY_PER_24MC_FCLK	This field indicates the state of the PER_24MC_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
15	CLKACTIVITY_12M_FCLK	This field indicates the state of the FUNC_12M_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
14	CLKACTIVITY_GPT9_FCLK	This field indicates the state of the DMT9_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
13	CLKACTIVITY_GPT4_FCLK	This field indicates the state of the DMT4_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
12	CLKACTIVITY_GPT3_FCLK	This field indicates the state of the DMT3_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
11	CLKACTIVITY_GPT2_FCLK	This field indicates the state of the DMT2_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
10	CLKACTIVITY_GPT11_FCLK	This field indicates the state of the DMT11_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
9	CLKACTIVITY_GPT10_FCLK	This field indicates the state of the DMT10_FCLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0

Bits	Field Name	Description	Type	Reset
8	CLKACTIVITY_L4_PER_ICLK	This field indicates the state of the L4_PER_GICLK clock in the domain. [warm reset insensitive] Read 0x0: Corresponding clock is definitely gated Read 0x1: Corresponding clock is running or gating/ungating transition is ongoing	R	0
7:2	RESERVED		R	0x00
1:0	CLKTRCTRL	Controls the clock state transition of the L4PER clock domain. 0x0: NO_SLEEP: Sleep transition cannot be initiated. Wakeup transition may however occur. 0x1: SW_SLEEP: Start a software forced sleep transition on the domain. 0x2: SW_WKUP: Start a software forced wake-up transition on the domain. 0x3: HW_AUTO: Automatic transition is enabled. Sleep and wakeup transition are based upon hardware conditions.	RW	0x0

## Dual Cortex-A9 MPU Subsystem

---

---

---

This chapter describes the dual Cortex™-A9 MPU subsystem.

Topic	Page
4.1 Dual Cortex-A9 MPU Subsystem Overview .....	1088
4.2 Dual Cortex-A9 MPU Subsystem Integration .....	1091
4.3 Dual Cortex-A9 MPU Subsystem Functional Description .....	1096
4.4 Dual Cortex-A9 MPU Subsystem Register Manual .....	1124

## 4.1 Dual Cortex-A9 MPU Subsystem Overview

### 4.1.1 Introduction

The dual Cortex™-A9 microprocessor unit (MPU) subsystem of the device is based on the symmetric multiprocessor (SMP) architecture. Thus, the dual Cortex-A9 MPU subsystem delivers higher performance, optimal power management, and debug and emulation capabilities.

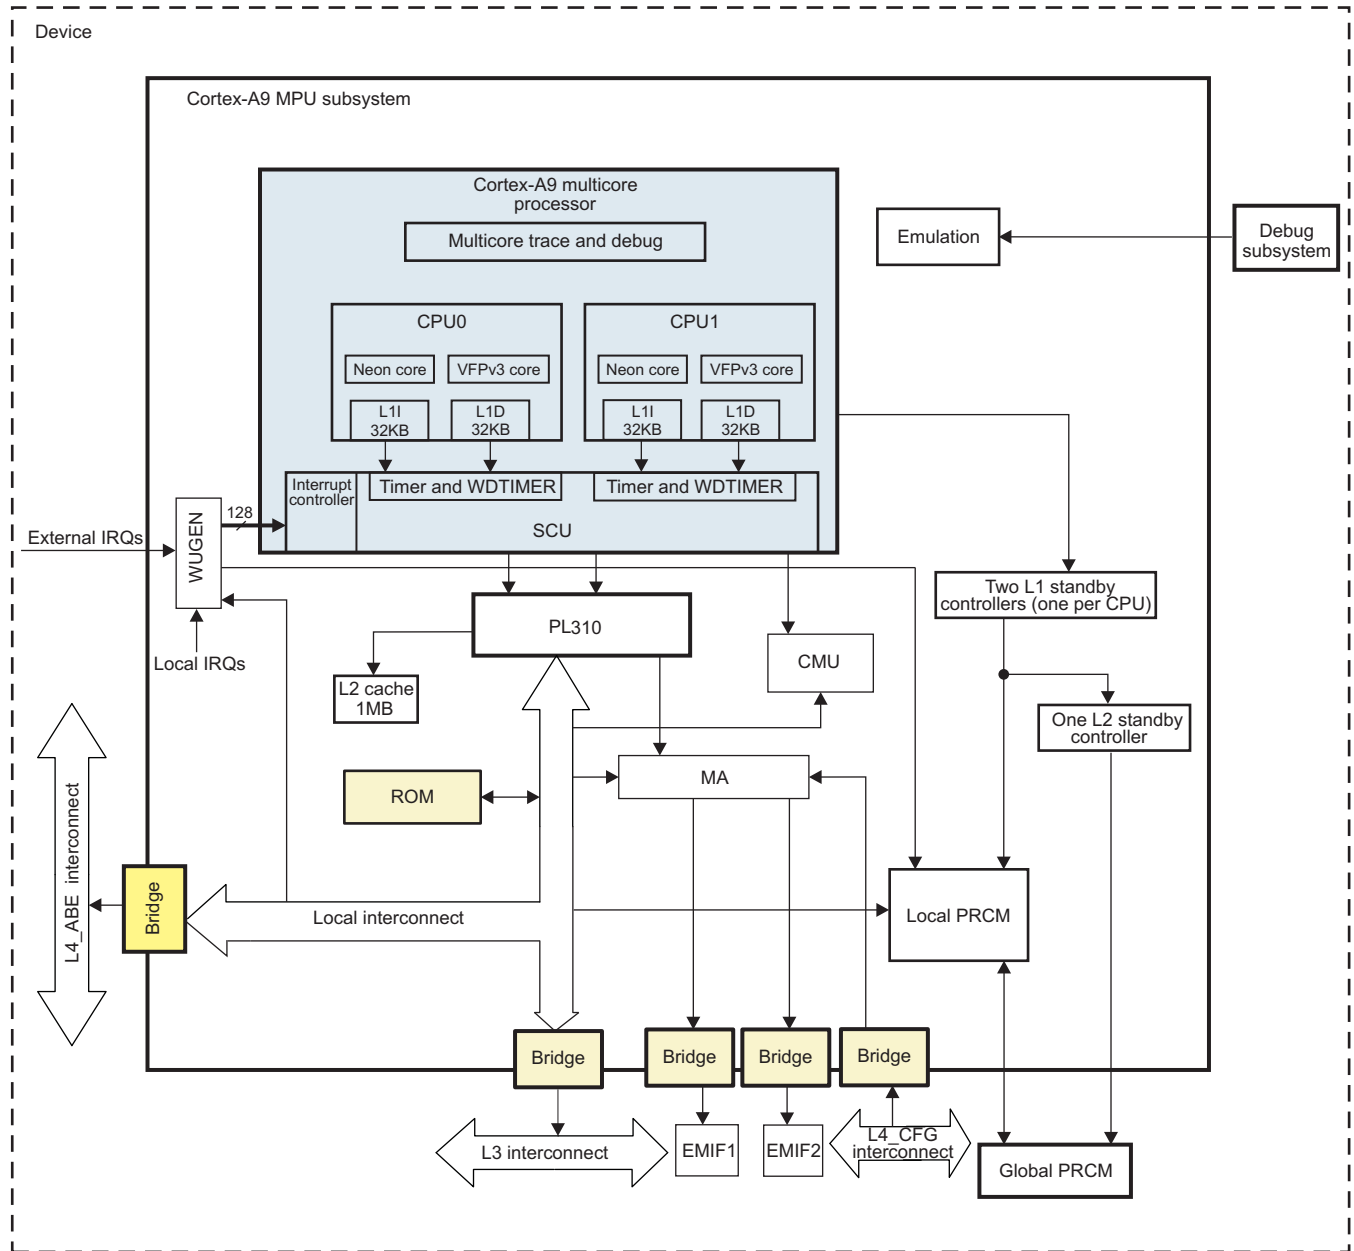

The dual Cortex-A9 MPU subsystem incorporates two Cortex-A9 central processing units (CPUs), level 2 (L2) cache shared between the two CPUs, and uses PL310 as an L2 cache controller. Each CPU has 32KB of level 1 (L1) instruction cache, 32KB of L1 data cache, separate dedicated power domain, and includes one Neon™ and Vector Floating Point Unit (VFPv3) coprocessors. The dual Cortex-A9 MPU subsystem also includes standard CoreSight™ components to support SMP debug and emulation, snoop control unit (SCU), interrupt controller (GIC), clock and reset manager, Memory Adapter (MA) and Cache Management Unit (CMU).

The MPU subsystem handles transactions among the ARM® core, L3 interconnect, EMIF controller (through the MA), L4-ABE, and interrupt controller (INTC).

Hereafter in this chapter, references to the dual Cortex-A9 MPU subsystem, Cortex-A9 MPU subsystem, and MPU subsystem are equivalent.

[Figure 4-1](#) shows a high-level block diagram of the MPU subsystem.

Figure 4-1. Cortex-A9 MPU Subsystem Overview

mpu\_a9-001

### 4.1.2 Features

The Cortex-A9 MPU subsystem integrates the following:

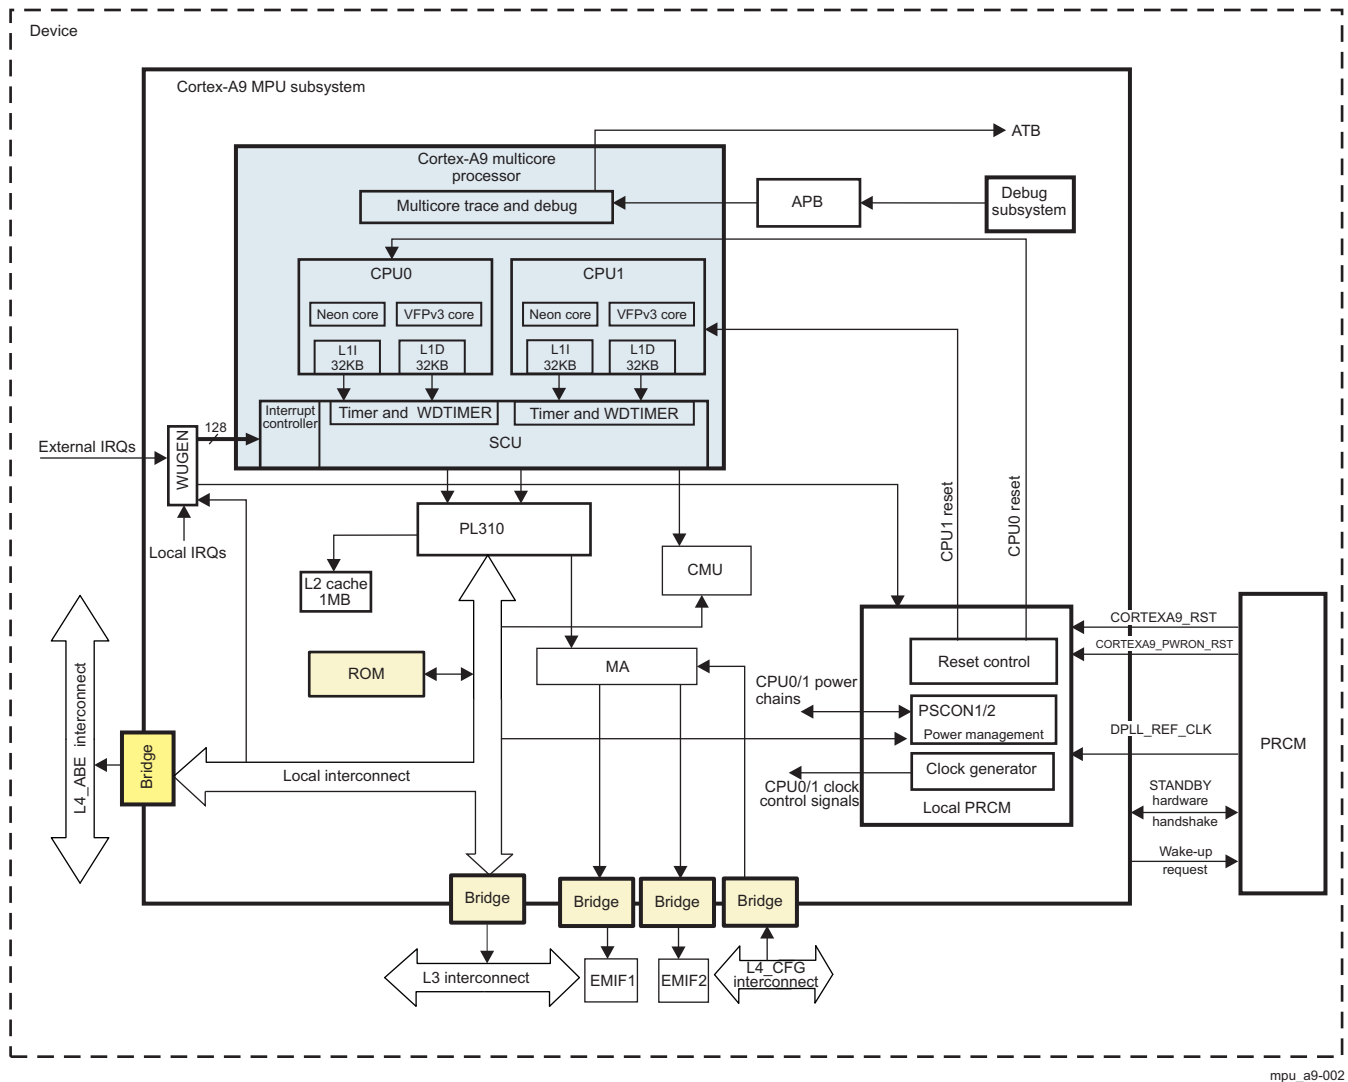

- ARM subchip
  - Cortex-A9 core revision r2p10
  - SMP architecture
  - Superscalar, dynamic multiple issue technology with an efficient 8-stage pipeline
  - Out-of-order (OoO) instruction dispatch and completion
  - ARM Neon™ Advanced SIMD (single instruction, multiple data) support for accelerated media and signal processing computation.
  - Include VFPv3 hardware to support single and double-precision add, subtract, divide, multiply and accumulate, and square root operations
  - 32KB L1 instruction and 32-KB L1 data cache – 32-byte line size, 4-way set associative
  - Memory management unit (MMU)
    - Two-level translation lookaside buffer (TLB) organization
    - First level is an 32-entry, fully associative micro-TLB implemented on the Instruction and Data side.
    - Second level is a unified, 2-way associative, 128-entry main TLB
    - Supports hardware TLB table-walk
  - SCU ensures memory coherency between the two CPUs
  - Integrated timer and watchdog timer per CPU
  - Interrupt controller with 128 hardware interrupt inputs
- PL310 L2 cache controller (revision r3p1-50rel0) with 1-MB cache size
  - 16-way set associative
  - 32-byte line size
  - PL310 address filtering function used to split accesses between MA and Local interconnect
  - Two slave ports and two master ports
  - Includes four 256-bit line-fill-buffers (LFBs) shared by the master ports
  - Each slave port includes two 256-bit line-read-buffers (LRBs)
  - Includes four 256-bit store buffers with merge capability
  - Support for 64-byte line fills issued to L3
- Program trace macrocell (PTM)
- Emulation logic (cross-triggers)
- AMBA advanced trace bus (ATB) trace port
- Advanced peripheral bus (APB) port
- ROM memory
- Wake-up generator (WUGEN) module: Responsible for waking up the CPUs
- Standby controllers: The Cortex-A9 MPU implements a two-level standby controller consisting of two L1 standby controllers (one per CPU) and one L2 standby controller. The standby controllers handle the power transitions inside the Cortex-A9 MPU subsystem.
- Interface to audio back-end (ABE) subsystem: Enables direct connection between the Cortex-A9 multicore processor and the ABE module to reduce power consumption during long audio playback
- Power, clock, and reset manager: The Cortex-A9 MPU subsystem implements a local PRCM module to handle CPU power domains.
- MA
- CMU

## 4.2 Dual Cortex-A9 MPU Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 4-2 shows the Cortex-A9 MPU integration.

**Figure 4-2. Cortex-A9 MPU Subsystem Integration**

mpu\_a9-002

**NOTE:** For more information about the STANDBY hardware handshake and the wake-up request, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 4-1 and Table 4-2 summarize the integration of the module in the device.

**Table 4-1. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
CORTEXA9	PD_MPU	L3

**Table 4-2. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CORTEXA9	MPU_DPLL_CLK	MPU_DPLL_CLK	PRCM	Interface and functional clock
Resets				
CORTEXA9	CORTEXA9_PWRON_RSTN	CORTEXA9_PWRON_RSTN	PRCM	Power-on reset (POR) for all the modules inside the MPU system power domain; nonretention
	CORTEXA9_RSTN	CORTEXA9_RSTN	PRCM	Warm reset for all the modules inside the MPU system power domain; nonretention

### 4.2.1 Clock Distribution

The Cortex-A9 MPU clock generator is fed by the MPU digital phase-locked loop (DPLL), which can be gated off by the global power, reset, and clock management (PRCM) module when system power domain is in a low-power state. There is a global clock gating for each CPU. Because of the MPU DPLL, the Cortex-A9 MPU subsystem is asynchronous from the rest of the device.

The clock generator generates the following clocks from the MPU DPLL output clock:

- ARM\_FCLK: ARM Cortex-A9 MPCore functional clock
- LOCAL\_INTCNT\_FCLK: Local interconnect functional clock
- CACHE\_CTRL\_FCLK: PL310 cache controller functional clock
- CMU\_CLK1 and CMU\_CLK2: CMU functional clocks
- MA\_CLK1, MA\_CLK2 and MA\_CLK3: MA functional clocks

The following clocks have the same frequency:

- ARM\_FCLK
- CACHE\_CTRL\_FCLK
- CMU\_CLK1
- MA\_CLK1

The frequency of the following clocks is half of ARM\_FCLK:

- LOCAL\_INTCNT\_FCLK
- CMU\_CLK2
- MA\_CLK2

The frequency of MA\_CLK3 is software-configurable (through the CM\_MPU\_MPU\_CLKCTRL[24] CLKSEL\_EMIF\_DIV\_MODE bit) and can be half of the ARM\_FCLK and one fourth of the ARM\_FCLK frequency.

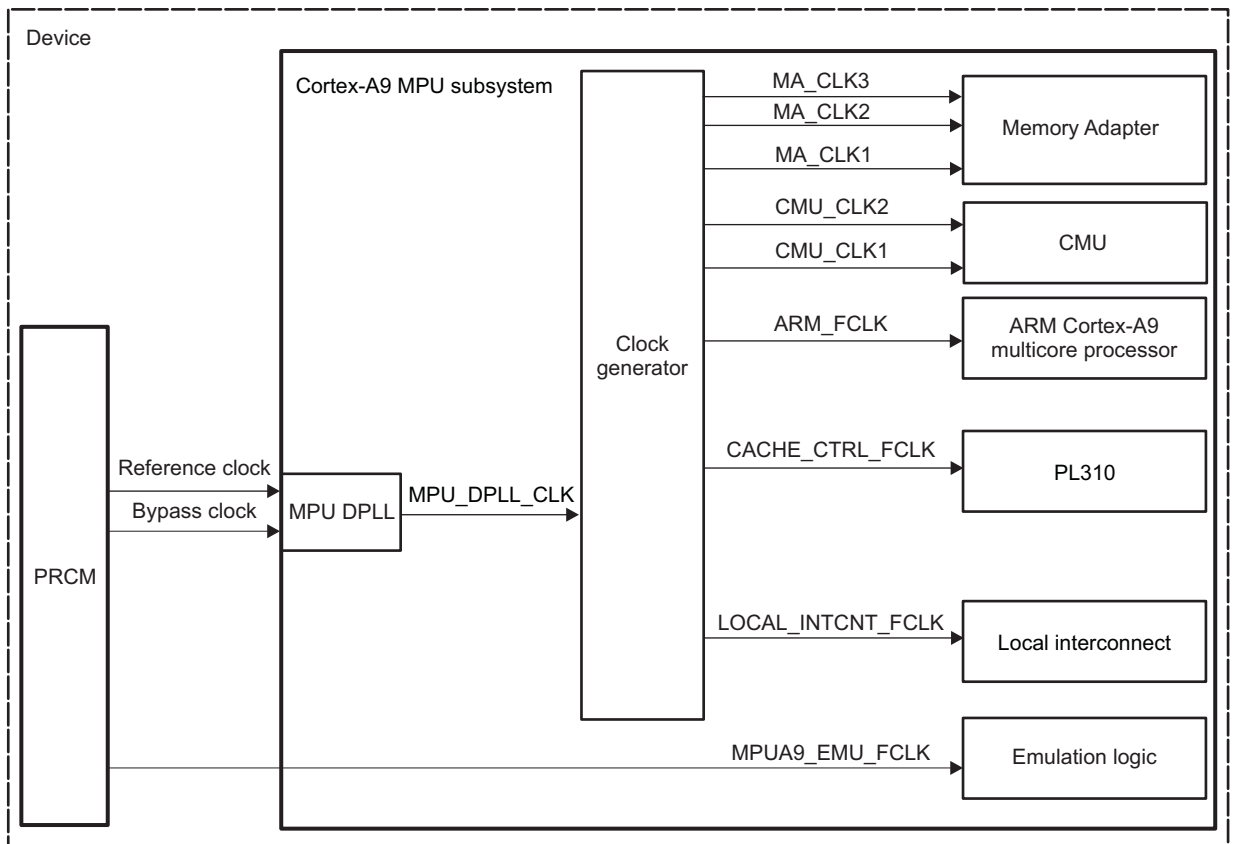

---

**NOTE:** For more information about setting the CM\_MPU\_MPU\_CLKCTRL[24] CLKSEL\_EMIF\_DIV\_MODE and CM\_MPU\_MPU\_CLKCTRL[25] CLKSEL\_ABE\_DIV\_MODE bits, see the *Data Manual Operating Condition Addendum*.

---

Figure 4-3 shows the MPU subsystem clocking scheme.

Figure 4-3. Cortex-A9 MPU Subsystem Clocking Scheme

mpu\_a9-003

**NOTE:** For more information about the MPU DPLL, see [Section 3.6.3.3, Generic DPLL Overview](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The reference clock in [Figure 4-3](#) is relevant to the DPLL\_REF\_CLK clock signal. The ARM Cortex-A9 multicore processor has no wake-up capabilities.

If only one Cortex-A9 CPU is needed, the ARM\_FCLK can be gated independently for each CPU. For more information about how to gate this clock, see [Section 4.3.6.2, Power States of CPU0 and CPU1](#).

The two Cortex-A9 CPUs cannot be clocked at different frequencies.

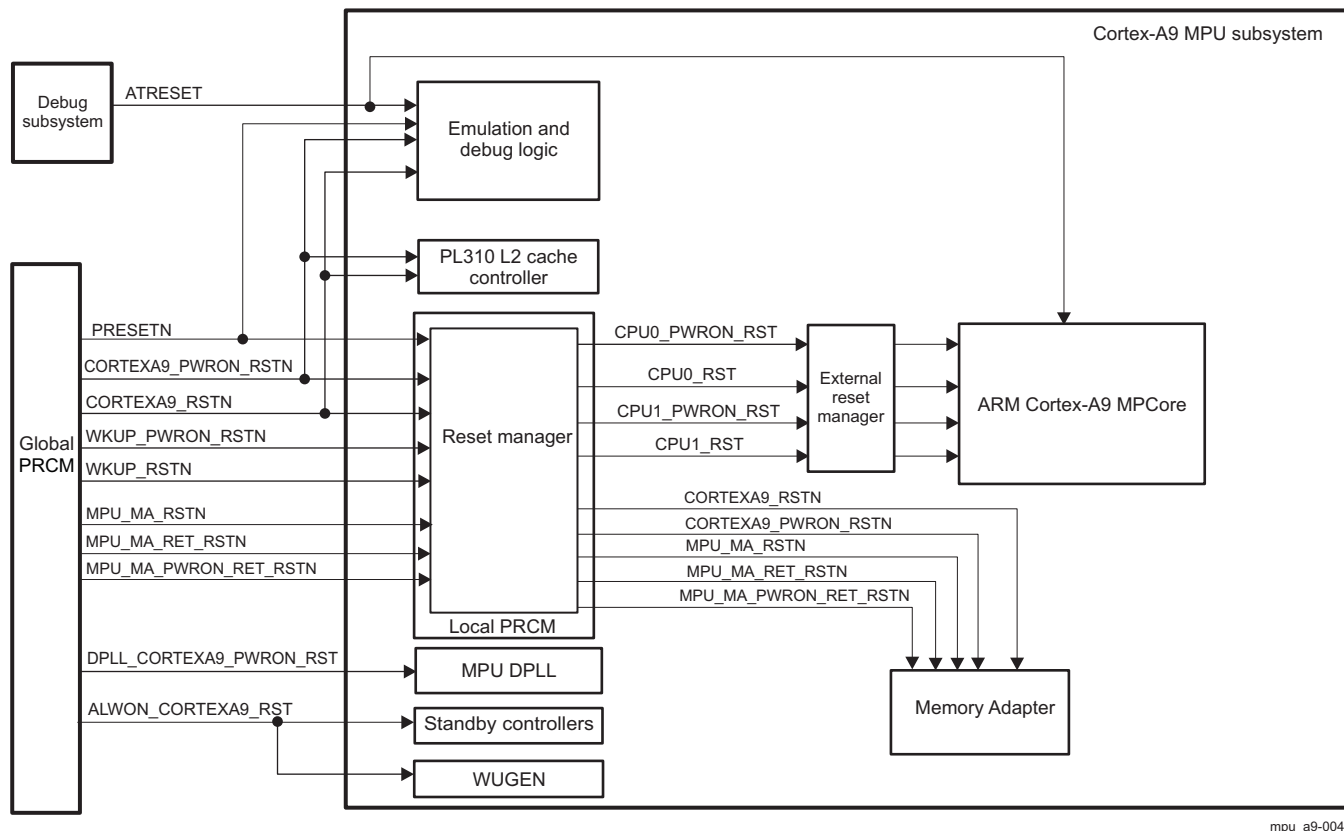

#### 4.2.2 Reset Distribution

Resets to the MPU subsystem are provided by the global PRM module and controlled by the local PRM module.

For more information about the power domains in the Cortex-A9 MPU subsystem, see [Section 4.3.6.1, Power Domains](#). [Figure 4-4](#) shows the reset scheme of the MPU subsystem.

Figure 4-4. Cortex-A9 MPU Subsystem Reset Scheme

mpu\_a9-004

All eight external resets that are input to the local PRCM signals are active low. All eleven external reset input signals are driven by the global PRCM, except the ATRESETN reset signal, which is driven by the device debug subsystem. There are four internal reset signals that are generated by the local PRCM module.

ATRESETN is asserted at initial device power up and resets the debug and trace modules. ATRESETN affects the debug logic of the Cortex-A9 MPU and ARM CPUs.

The PRESETN reset signal resets the debug logic in the Cortex-A9 MPU (CTI0/1, trace funnel, DAP\_PC) and ARM CPUs.

The WKUP\_PWRON\_RSTN reset signal is a global cold reset for the wake-up logic and resets the wake-up domain logic (the PSCON modules) in the local PRCM module. A cold reset is typically asserted when power is initially applied to the system. The user can check whether this reset event has occurred by reading the [PRM\\_RSTST\[0\]](#) GLOBAL\_COLD\_RESET bit.

The WKUP\_RSTN reset signal is a global warm reset that resets the wake-up domain logic (the PSCON modules) in the local PRCM module. Warm reset is typically used for resetting a system that has been operating for some time. The user can check whether this reset event has occurred by reading the [PRM\\_RSTST\[1\]](#) GLOBAL\_WARM\_RST bit.

The DPLL\_CORTEXA9\_PWRON\_RST reset signal resets the MPU\_DPLL.

The ALWON\_CORTEXA9\_RST reset signal resets the MPU always-on domain: The standby controllers and the WUGEN. The user can check whether the reset has occurred by reading the [WKG\\_CONTROL\\_0\[15\]](#) DOMAIN\_RST bit for CPU0 and the [WKG\\_CONTROL\\_1\[15\]](#) DOMAIN\_RST bit for CPU1.

The MA has five incoming reset signals:

- CORTEXA9\_RSTN
- CORTEXA9\_PWRON\_RSTN

- MPU\_MA\_RSTN
- MPU\_MA\_RET\_RSTN
- MPU\_MA\_PWRON\_RET\_RSTN

These five reset signals are driven by the Cortex-A9 MPU local reset manager and are active low.

The local PRCM module provides two reset signals for each CPU:

- The CPU0\_RST and CPU1\_RST reset signals are warm reset events. These reset signals initialize most of the ARM CPUs, except the debug logic (breakpoints and watchpoints are retained during this reset). The user can check whether these reset events have occurred by reading the [RM\\_PDA\\_CPUi\\_RSTCTRL\[0\]](#) RST bit.
- The CPU0\_PWRON\_RST and CPU1\_PWRON\_RST reset signals are cold and debug reset events.

For more information about clocks, resets, and power domains, and the CORTEXA9\_PWRON\_RSTN and CORTEXA9\_RSTN reset signals, see [Chapter 3, Power, Reset, and Clock Management](#).

## 4.3 Dual Cortex-A9 MPU Subsystem Functional Description

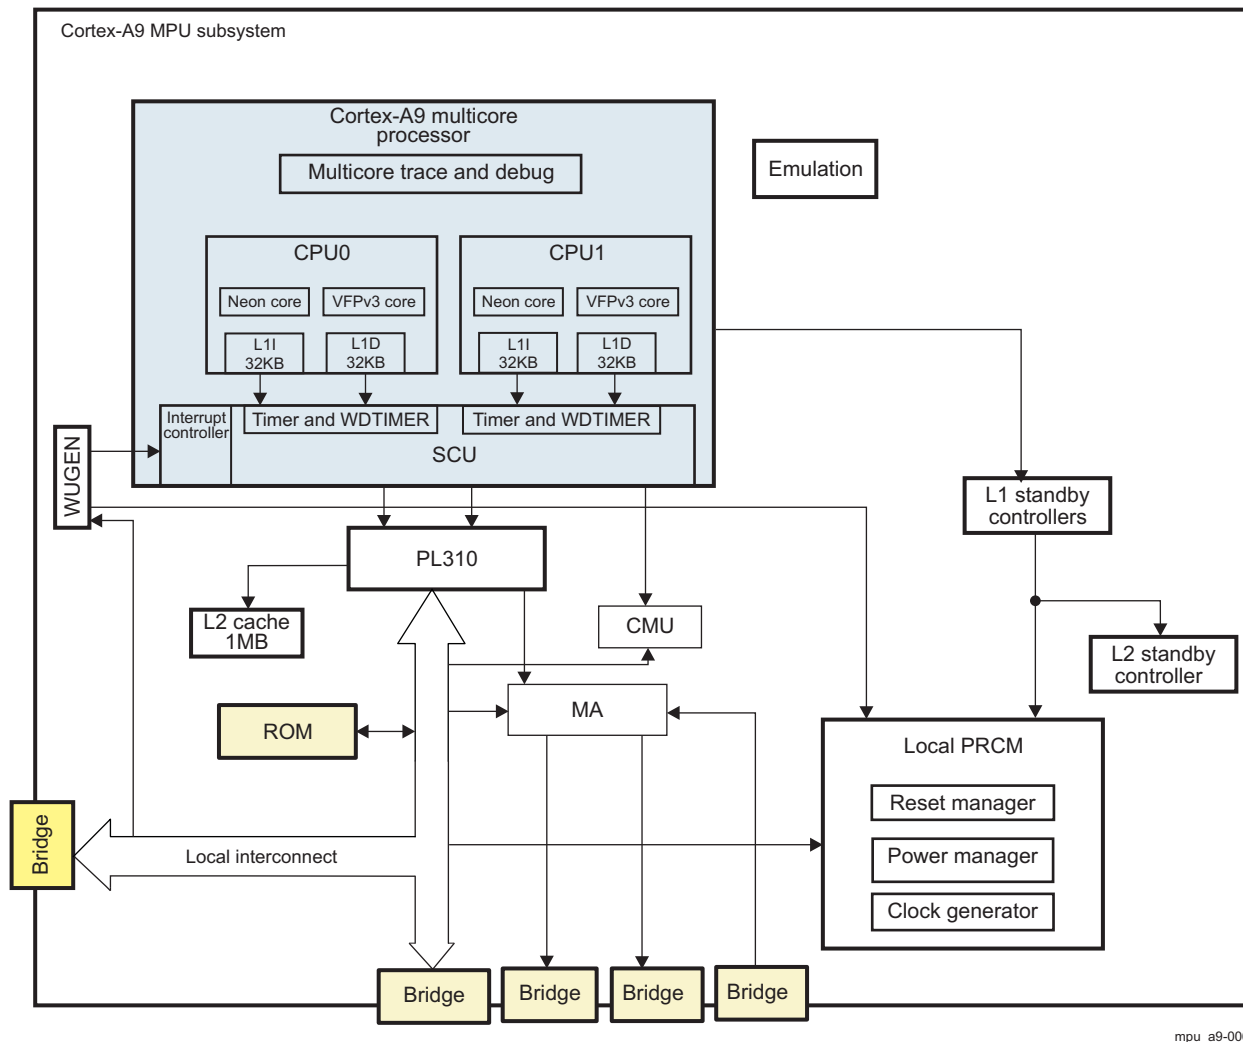

### 4.3.1 Cortex-A9 MPU Subsystem Block Diagram

The Cortex-A9 MPU subsystem integrates the following group of submodules:

- Two ARM Cortex-A9 CPUs. Each CPU contains:
  - ARM version 7 ISA™: Standard ARM instruction set plus Thumb®-2 , Jazelle® RCT, and Jazelle DBX Java™ accelerator
  - Neon SIMD coprocessor and VFPv3
- INTC: Handles module interrupts (for more information, see [Chapter 17, Interrupt Controller](#))
- PL310 L2 cache controller (revision r3p1-50rel0) with 1-MB cache and two 64-bit slave and two 64-bit master ports (for more information about the L2 cache controller, see the *ARM PL310 Cache Controller TRM* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).
- Local interconnect: Connects the ARM Cortex-A9 multicore processor to:
  - Level 3 (L3) interconnect
  - ABE interconnect
  - Local PRCM module
  - PL310 L2 cache controller
  - On-chip ROM
  - WUGEN
  - CMU
  - MA
- Power, clock, and reset manager
- On-chip ROM: CPU0 (the master CPU) can boot from this memory. The ROM size is 48KB, and the address range is from 0x4003 0000 to 0x4003 BFFF. For more information, see [Chapter 27, Initialization](#).
- WUGEN: Responsible for waking up the CPUs, used by the ROM code and OS during SMP boot. Two internal memory-mapped registers ([AUX\\_CORE\\_BOOT\\_0](#) and [AUX\\_CORE\\_BOOT\\_1](#)) are available to the OS for communicating start-up information. For more information, see [Chapter 27, Initialization](#).
- Standby controllers: Handle the power transitions inside the Cortex-A9 MPU subsystem
- SCU for L1 cache coherency
- One timer and one watchdog unit per core
- Caches memories:
  - 32-KB L1 instruction and 32-KB data caches: 4-way associative on each core
  - 1-MB L2 unified cache: 16-way associative
- MA
- CMU

[Figure 4-5](#) is the Cortex-A9 MPU block diagram.

Figure 4-5. Cortex-A9 MPU Block Diagram

### 4.3.2 ARM Core

The Cortex-A9 MPU subsystem implements ARM version 7 ISA. Table 4-3 lists the main functions of the Cortex-A9 core.

Table 4-3. ARM Core Key Features

Feature	Comment
ARM version 7 ISA	Standard ARM instruction set + Thumb-2, Jazelle RCT/DBX Java accelerator, and media extensions. Backward-compatible with previous ARM ISA versions.
L1 Icache and Dcache	32KB each

**Table 4-3. ARM Core Key Features (continued)**

Feature	Comment
L2 cache (PL310)	Main characteristics are: <ul style="list-style-type: none"> <li>• Physically addressed and physically tagged</li> <li>• 16-way associative</li> <li>• 32-byte line length</li> <li>• Critical word first transactions</li> <li>• Prefetching capability</li> <li>• Pseudo-random victim selection policy</li> <li>• Two 256-bit LFBs in each master port</li> <li>• Two 256-bit LRBs in each slave port</li> <li>• Three 256-bit write buffers (merging capable)</li> <li>• Three 256-bit eviction buffers</li> <li>• Two 64-bit slave ports from SCU</li> <li>• Two master ports, one 64-bit port to L3 (through the Local interconnect) and one 128-bit port to EMIF (through the MA)</li> <li>• PL310 address filtering function used to split accesses between MA and Local interconnect</li> <li>• Support for 64-byte line fills issued to L3</li> </ul>
SCU	The SCU controls by hardware the coherency of the two Cortex-A9 MPCores L1 data caches. The SCU supports up to four outstanding reads for each CPU. The SCU can be given an address range that redirects all memory transactions within this range to the second master ports (to L2 cache controller).
TLB	Two levels: Micro TLB (32 entries on each of instruction and data sides) + main TLB (instruction/data unified) implemented as a combination of a fully associative array of 4 elements (lockable) + a low-associative, 128 entries, 2-way
Trace interface	One program trace macrocell (PTM) per core
Branch prediction	512 entries per core + global history buffer (GHB) of 4096 2-bit predictors + 8-entry return stack
Enhanced MMU	Mapping sizes are 4KB, 64KB, 1MB, and 16MB.
Neon	Includes advanced SIMD instructions and the ARM VFPv3 instructions

### 4.3.3 Local Interconnect

The local interconnect is used in the device design to connect one of the 64-bit buses of the PL310 L2 cache controller to the L3 interconnect (64-bit width), MA, ABE interconnect port (32-bit width), and local power manager. The local interconnect must do some minimal address decoding to decide where to forward the requests.

Main features:

- Connects to the L3 interconnect through a 64-bit port. The interface frequency is configurable between one half (default value) and one fourth of the MPU\_DPLL\_CLK clock signal frequency. This is programmable in the CM\_MPU\_MPU\_CLKCTRL[24] CLKSEL\_EMIF\_DIV\_MODE bit.
- Connects to the ABE through a 32-bit port. The interface frequency is configurable between one fourth (default value) and one eighth of the MPU\_DPLL\_CLK clock signal frequency. This is programmable in the CM\_MPU\_MPU\_CLKCTRL[25] CLKSEL\_ABE\_DIV\_MODE bit.

---

**NOTE:** For more information about setting the CM\_MPU\_MPU\_CLKCTRL[24] CLKSEL\_EMIF\_DIV\_MODE and CM\_MPU\_MPU\_CLKCTRL[25] CLKSEL\_ABE\_DIV\_MODE bits, see the *Data Manual Operating Condition Addendum*.

---

- Connection to the CMU for register configuration
- Connection to the MA for register configuration
- Contains internal configuration register related to the MA function
- Supports single-request-multiple-data (data handshaking) burst mode to pipeline requests
- Supports multiple outstanding requests

- Supports posted and nonposted write transactions, based on the attributes of the transactions coming from the ARM Cortex-A9 processor. Software can override all writes from the local interconnect to the L3 interconnect to be nonposted, regardless of the attributes of the transactions coming from the ARM Cortex-A9 processor, by setting the FORCEWRNP[0] MPUFORCEWRNP bit to 0x1. For the register description, see [Chapter 18, Control Module](#).

---

**NOTE:** For the register description of the CM\_MPU\_MPU\_CLKCTRL, see [Chapter 3, Power, Reset, and Clock Management](#).

---

#### 4.3.4 Memory Adapter

The purpose of the MA is to improve the missed latency of the L2 cache between the ARM Cortex-A9 processor and external memory. One of the PL310 master ports is connected to the MA and is used for all accesses to SDRAM. The PL310 address filtering mechanism is used to split incoming addresses between the MA connected to one of the PL310 master ports and the local interconnect connected to the other PL310 master port.

Requests from the MA to the EMIF typically run at half the CPU frequency. In high-speed (turbo) mode, when the CPU runs at higher frequency, these requests can be run at one fourth of the CPU frequency. The MA matches the bandwidth of the PL310 port on burst accesses by packing the write data to 128-bit-wide words and unpacking the 128-bit read data at full processor speed. Because the MA duplicates some of the logic in the local interconnect and DMM module, the MA has similar functionality.

The main features of the MA are:

- Connected to the PL310 slave port
- Direct 128-bit interface each to EMIF1 and EMIF2
  - Single request multiple data
  - No write response on posted writes
- Full-speed interface to the PL310 L2 cache controller
- Programmable half-speed (default is one half) or one-fourth speed interface to the EMIF (EMIF1 and EMIF2). This is selected by the CM\_MPU\_MPU\_CLKCTRL[24] CLKSEL\_EMIF\_DIV\_MODE bit.

---

**NOTE:** For more information about setting the CM\_MPU\_MPU\_CLKCTRL[24] CLKSEL\_EMIF\_DIV\_MODE and CM\_MPU\_MPU\_CLKCTRL[25] CLKSEL\_ABE\_DIV\_MODE bits, see the *Data Manual Operating Condition Addendum*.

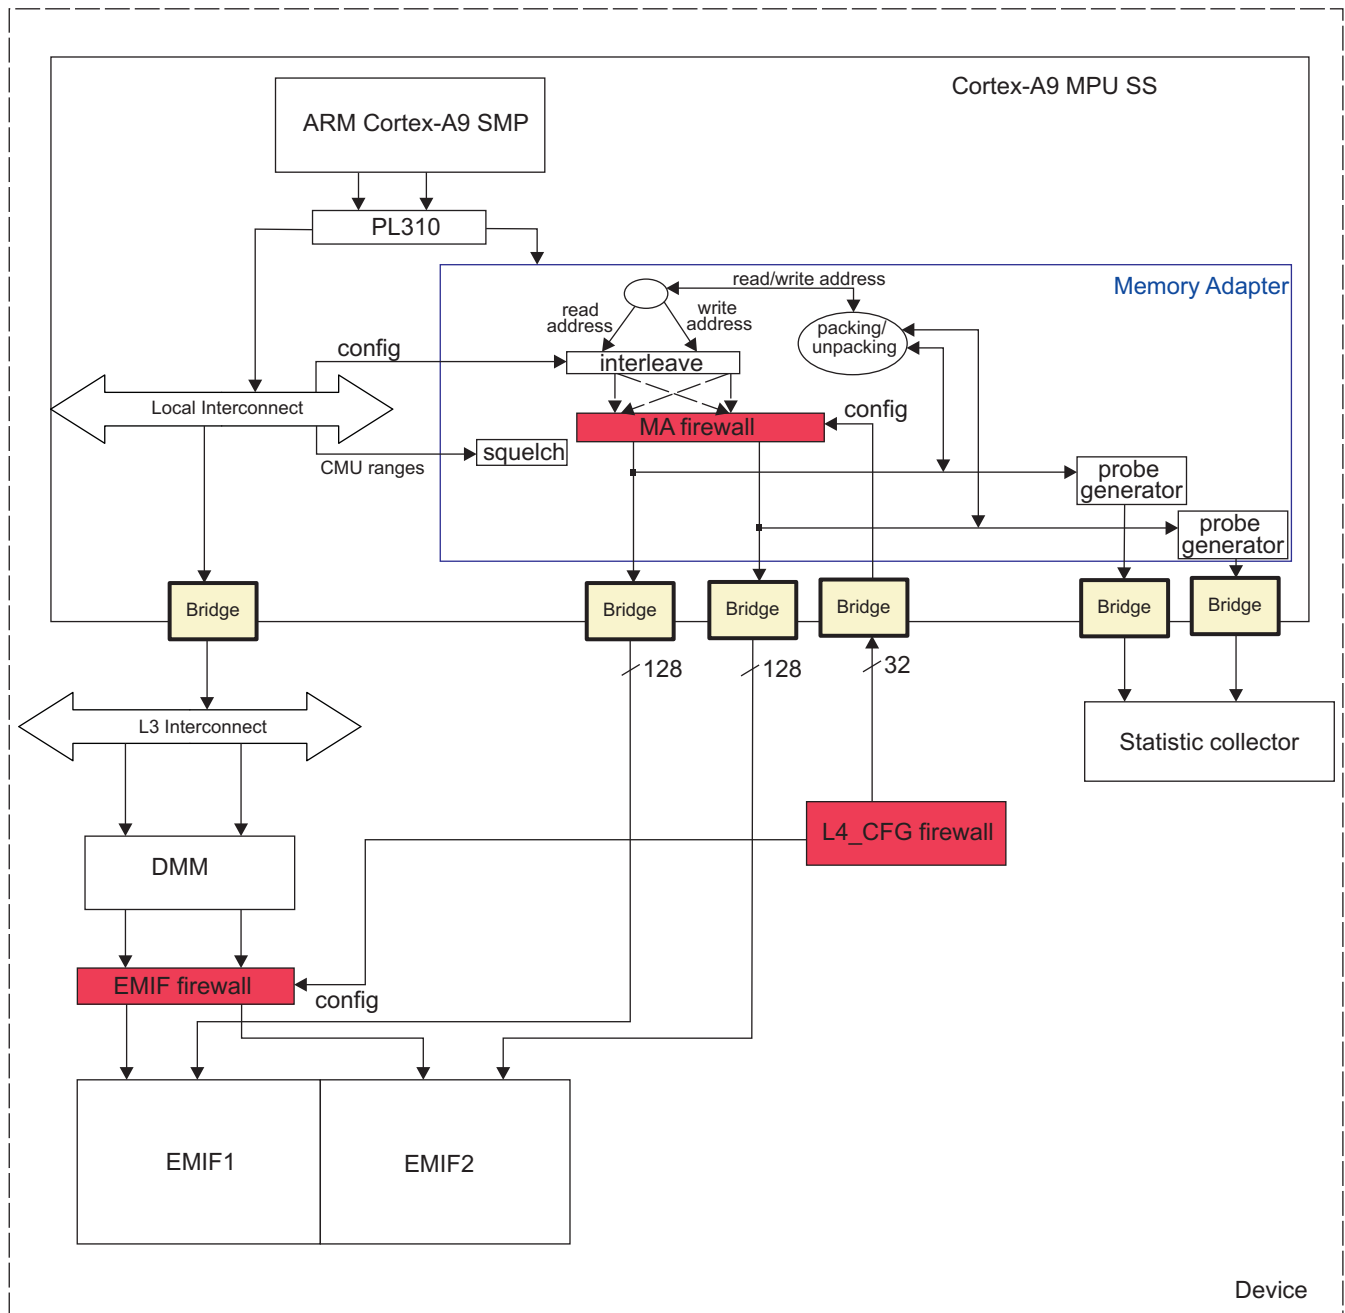

---

- Performs interleaving functions to optimize the bandwidth of the EMIF
- Uses firewall logic to check access rights of incoming addresses. The firewall on both EMIF supports:
  - Configurable number of regions with fixed priority
  - Access support for up to eight execution domains
  - Busy indicator during reconfiguration
- Blocked read and write access to the EMIF for all accesses failing authorization checks
- Parallel processing of reads and writes
- Packing of burst write data into 128-bit words at full processor clock speeds
- Unpacking of burst read data into 64-bit words at full processor clock speeds
- Support for narrow bursts
- Burst wrap for single and double cache line fills.
- Supports the CMU by squelching dummy accesses (single thread operation only)
- Supports boot from EMIF space
- MA section manager (SM) supports:
  - Programmable multi-zone DRAM mapping and interleaving configuration
  - Supports 4 prioritized sections for defining configuration regions within the external memory

- Supports interleaving at 128-, 256-, and 512-byte boundaries
- Supports standard disconnect and idle protocols for independent powering down of the MA and both EMIFs (the EMIF must be powered down or up as a pair).
- Probe interface for performance monitoring of the EMIF ports
- Splits all read bursts that cross 1-KB boundaries

Figure 4-6 shows the integration of the MA in the device.

**Figure 4-6. MA Block Diagram**

mpu\_a9-008

### 4.3.4.1 MA Functional Description

#### 4.3.4.1.1 Input Interface

The input is driven from one of the PL310 master ports. Only accesses that target EMIF external space appear on this interface. All accesses to the configuration registers of the EMIF, firewall, and MA SM appear on the other master port of the PL310 and are routed through the local interconnect.

#### 4.3.4.1.2 Interleaving

To optimize the bandwidth of the two EMIFs and their associated DDR memories, an interleaving scheme can be enabled. This interleaving is programmable and supports interleaving on 128-, 256-, and 512-byte boundaries. The programming can be performed in the MA\_LISA\_MAP\_i[19:18] SDRG\_INTL (where i = 0 to 3) bit fields. Some address translation is also part of this interleaving function. Because the EMIF memories are accessible by the Cortex-A9 MPU through the MA and the L3 interconnect through the DMM, the same interleaving scheme must be used. To ensure compatibility, the interleaving function is implemented by a scaled-down version of the MA SM, which implements the interleaving function in the DMM. For more information about the interleaving scheme of the MA SM, see [Section 15.2.3.5.1.1, Dynamic Mapping](#), and [Section 15.2.3.5.1.2, Address Mapping](#), in [Section 15.2, Dynamic Memory Manager](#). When reading, replace DMM with MA SM.

#### 4.3.4.1.2.1 Section Manager

The SM module in the MA contains one set of registers and three ports. Each port can handle one address translation, provide the interface size, and determine the EMIF mapping. Two of the ports process read and write addresses simultaneously. The third port processes the address of a split read burst. The MA SM supports four sections.

#### 4.3.4.1.2.2 Memory Adapter Registers

[Table 4-4](#) lists the DMM registers that are duplicated locally in the MA. These registers have the same names except that DMM is replaced by MA. Software must keep the content of these registers equal to the content of their counterparts in the DMM module.

**Table 4-4. MA Registers Duplicated From the DMM Register Map**

Register	Type	Width (Bits)	Base Address
MA_LISA_LOCK	RW	32	0x482A F01C
MA_LISA_MAP_P_i (where i = 0 to 3)	RW	32	From 0x482A F040 to 0x482A F04C

For descriptions of the registers, see [Section 15.2.6.2.2, DMM Register Description](#), in [Section 15.2, Dynamic Memory Manager](#). The only differences are the following reset values of the MA\_LISA\_MAP\_0 register:

- MA\_LISA\_MAP\_0[22:20] SYS\_SIZE = 0x1 (32-MB section)
- MA\_LISA\_MAP\_0[17:16] SDRG\_ADDRSPC = 0x1
- MA\_LISA\_MAP\_0[9:8] SDRG\_MAP = 0x1

The configuration of the MA must be programmed by the Cortex-A9 MPU to match the configuration of the DMM during boot. The registers must be locked after initial programming to avoid corruption by application software. When the SM configuration registers are being programmed there are no interlocks or safeguards to prevent accesses from being processed at the same time. The MA\_LISA\_LOCK and MA\_LISA\_MAP\_i registers are retained during power down of retention mode.

If an access is made to a region marked as having unused address space or an unmapped SDRG map, no access is made to the EMIF and an error is returned. If an access is made to a region marked as accesses-SDRG-internal-registers, no access occurs to the EMIF and an error is returned. This is because the internal registers are not accessible from this port.

#### 4.3.4.1.2.3 Posted and Nonposted Writes

On posted writes, a response is returned after all write data is accepted by the MA and one of the follow occurs:

- The request is canceled, because of an interleaving error or is stopped by the CMU logic.
- The request is pushed into the firewall FIFO.

On nonposted writes, a response is not returned until after all write data is accepted by the MA and one of the follow occurs:

- The request is canceled, because of an interleaving error or is stopped by the CMU logic.
- The request has a firewall violation.
- The associated response is received from the EMIF (access is completed in the EMIF).

When the FORCEWRNP[0] MPUFORCEWRNP bit is set to 0x1, all writes are forced to be converted to nonposted writes (prevents posted writes).

#### 4.3.4.1.2.4 Errors

If the region is marked as unmapped, targets EMIF internal registers or reserved space, access is blocked and an error response is returned. Such an error occurs on the first half of a potential split access and aborts the entire access at that time.

To avoid undefined results, the following program rules must be followed:

- A section cannot be mapped as interleaving (MA\_LISA\_MAP\_i[9:8] SDRC\_MAP = 0x3), and the MA\_LISA\_MAP\_i[19:18] SDRC\_INTL bit field must be equal to 0x0.
- If the section maps to a single EMIF (MA\_LISA\_MAP\_i[9:8] SDRC\_MAP = 0x1 or 0x2), the MA\_LISA\_MAP\_i[7:0] SDRC\_ADDR bit field must be aligned to the MA\_LISA\_MAP\_i[22:20] SYS\_SIZE bit field (that is, the lower SDRC\_ADDR bits must be 0).
- If the section maps to both EMIFs (MA\_LISA\_MAP\_i[9:8] SDRC\_MAP = 0x3), the MA\_LISA\_MAP\_i[7:0] SDRC\_ADDR bit field must be aligned to MA\_LISA\_MAP\_i[22:20] SYS\_SIZE – 1, because the addressable space for each EMIF is half.
- If the section maps to both EMIFs (MA\_LISA\_MAP\_i[9:8] SDRC\_MAP = 0x3), the MA\_LISA\_MAP\_i[22:20] SYS\_SIZE bit field cannot be 0.

#### 4.3.4.1.3 CMU Access Squelching

The CMU allows blocks of memory space to be flushed from the cache in the background while the Cortex-A9 MPU runs other user code. The CMU accomplishes this by generating dummy read and write accesses through the PL310 accelerator coherency port (ACP), which evicts or invalidates the required lines. If these dummy accesses reach the MA, they must be killed and the appropriate response returned. For more information about the CMU, see [Section 4.3.5, Cache Management Unit](#).

#### 4.3.4.1.3.1 Statistics Collector Probe Ports

To enable performance monitoring by the debug subsystem, a subset of interconnect signals must be monitored and sent to a statistics collector in the CORE domain. For more information about the statistics collector, see [Chapter 28, On-Chip Debug Support](#).

#### 4.3.4.1.4 MA Firewall

A firewall exists between the interleaving logic and each of the EMIF ports. The firewall checks the address and access qualifiers against the permission attributes for the highest priority region to which the address belongs. If the access fails to get permission, a violation occurs and the fw\_func\_error or fw\_debug\_error outputs are asserted. The failing access is blocked and a slave error response is returned on the MA port for read and nonposted accesses. For more information about the MA firewall, see [Chapter 13, Interconnect](#).

#### **4.3.4.1.5 MA Power and Reset Management**

The MA supports a power-down state where the MA SM and FW configurations are retained. It also supports a save-and-restore operation where external logic saves the configuration state of the firewall (does not include the MA SM) and reloads it before the Cortex-A9 MPU is brought out of reset state. For more information about the save-and-restore operation, see *sDMA*.

The MA SM supports only smart-idle mode.

### **4.3.5 Cache Management Unit**

#### **4.3.5.1 Overview**

The CMU provides the ability to perform maintenance operations on Cortex-A9 MPU caches by physical address range. This reduces the execution time required by the Cortex-A9 CPUs to perform cache maintenance operations, while improving the overall throughput of maintenance operations. This frees the CPUs for other useful work. The registers inside the CMU are configured using the 32-bit interconnect configuration port from the local interconnect. The CMU operates at half the clock speed of the CPU core.

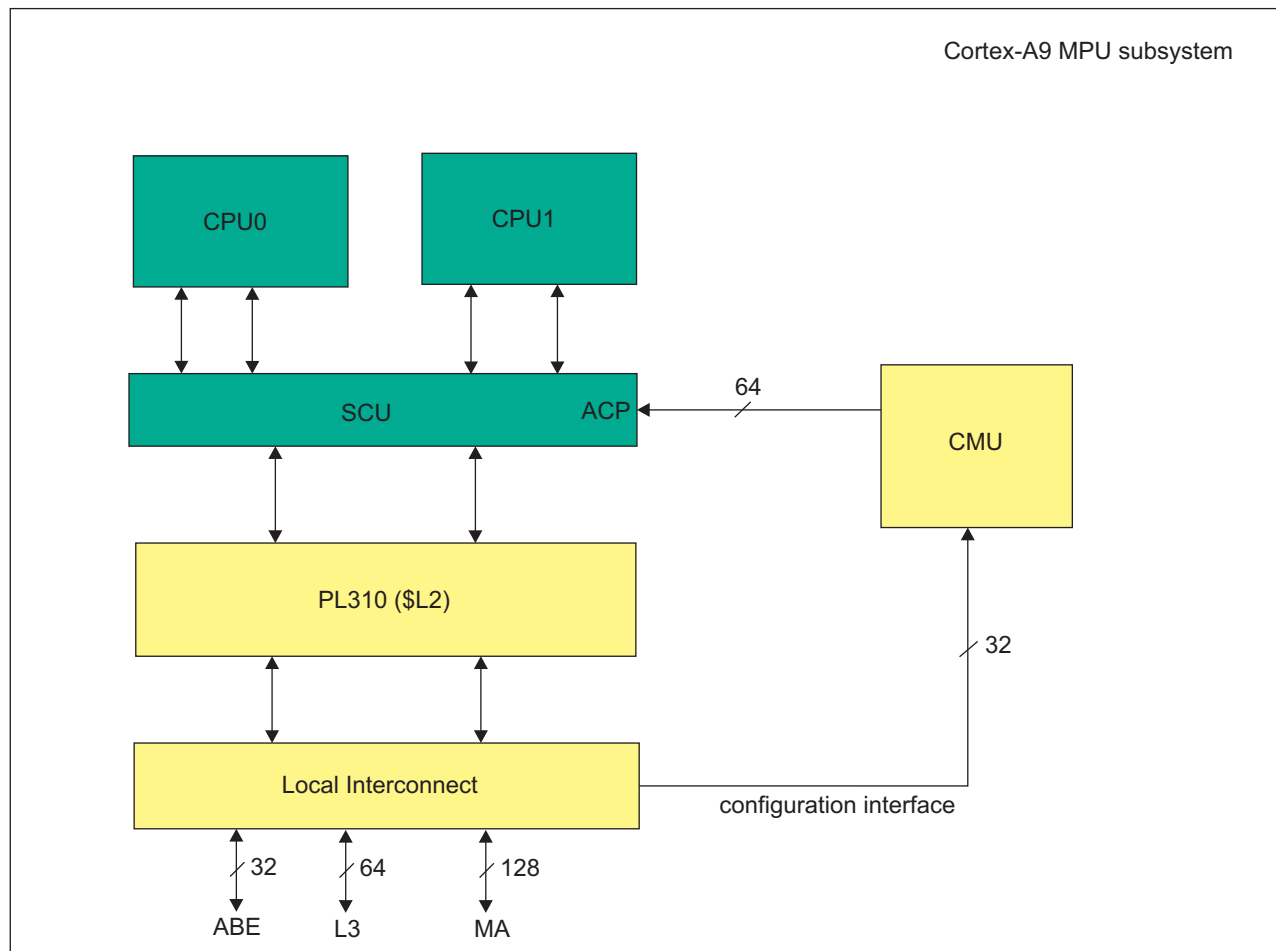

The main features of the CMU are:

- Autonomous cache invalidate and clean-and-invalidate operations on physical address ranges
- Multiprocessor and multiprogramming supported through built-in atomic range set allocation
- Independent programming of parameters in 64 range programming sets (RangeSets)
- Poll for status or interrupt on completion or error
- Handshake with power-management logic to ensure the CMU is idle before power management

The CMU indicates the idle status to the Cortex-A9 MPU subsystem, which implies all pending operations in the CMU are complete and is used by the local power-management logic to signal to the global PRCM module to shut down the domain clock and power of the Cortex-A9 MPU subsystem. The local power-management logic uses a handshake approach to ensure that the CMU completes all outstanding cache maintenance operations and enters IDLE state.

##### **4.3.5.1.1 Integration in the Cortex-A9 MPU Subsystem**

[Figure 4-6](#) shows the integration of the CMU into the Cortex-A9 MPU subsystem. The CMU is connected to the ACP of the SCU. The ACP is a 64-bit slave port over which the CMU can perform ACP reads and writes, coherent and noncoherent. The registers inside the CMU are configured using the 32-bit interconnect configuration port from the local interconnect.

**Figure 4-7. Integration of CMU in Cortex-A9 MPU Subsystem**

mpu\_a9-009

#### 4.3.5.1.2 Functionality

The CMU is programmed with:

- Starting physical address: [CMUSTARTPA\\_i\[31:0\]](#) STARTPA. It is a byte granular address and has no alignment restrictions.
- Length of region to be operated on: [CMULENGTH\\_i\[11:0\]](#) LEN. The maximum length can be as large as 4KB or as small as 1 byte. CMU operates on "line step" granularity, and the default value for line step is 32 bytes, which is the line size of the Cortex-A9 MPU. The line step can be programmed in the [CMUCONFIGREG\[2:0\]](#) LINESTEP bit field.
- Type of operation to be performed (clean/clean-invalidate/invalidate): [CMUOPERATION\\_i\[3:0\]](#) OPNSEL

This information is programmed in a structure called a range set.

The CMU performs the appropriate operation (clean/clean-invalidate/invalidate) on the address range in all cache levels on a line step basis and can be programmed to interrupt the processor when the operation completes, or to poll for the status. The CMU can generate an interrupt request (CMU\_IRQ\_P) to the Cortex-A9 MPU interrupt controller (mapped as MA\_IRQ\_6) when it finishes operating.

The CMU has 64 range sets. Allocation and deallocation of the 64 range sets is done as an explicit step in software. Allocation is performed by reading the [CMUALLOCATE](#) register. Deallocation is performed by writing in the [CMUDEALLOCATE](#) register. Two groups of registers can check the status of operations: [CMUOPERATION\\_i](#) and [CMURANGESTATE\\_i](#).

### 4.3.5.1.3 Clean/Clean-Invalidate/Invalidate Flow

For all flows, the following bits must be set in PL310 so that the L2 line is invalidated on a write if it hits in the L2 cache:

- Shared Attribute Override Enable = 0; bit 22 of the Auxiliary Control Register. This is the default behavior and transforms normal memory noncacheable transactions into:
  - Cacheable no allocate for reads: L2 is looked up.
  - Write Through (WT) and No Write Allocate (NWA) for writes: L2 is updated on a hit and write is sent to L3. These writes are done as part of the clean/clean-invalidate flow.
- Shared Attribute Invalidate Enable = 1; bit 13 of the Auxiliary Control Register. When this bit is set, the L2 line is invalidated in the L2 cache and a write is sent to L3.

#### 4.3.5.1.3.1 Clean/Clean-Invalidate Flow

For a clean/clean-invalidate operation:

1. The CMU performs an ACP read of the first line in the address range:
  - (a) If the address hit in L1 or L2, get data from L1 or L2. The CMU does not know where it came from.
  - (b) Else if the address missed in L1 and L2:
    - (i) PL310 sends a read request to L3.
    - (ii) The local interconnect returns a slave error to the CMU if the local interconnect sees a read request from the CMU/ACP and the CMU ends the operation on that line.
2. If the ACP read did not abort, the CMU performs an ACP write of data returned from the ACP read (all bytes valid ). This is called as an optimized transfer.
  - (a) ACP write of all bytes invalidates the line in L1: Cortex-A9 behavior
  - (b) ACP write goes to PL310 where if the address hits, the PL310 line is invalidated. To optimize CMU flows, some auxiliary control bits must be set to make use of the "invalidate L2 line if it hits" feature.
  - (c) ACP writes the data to L3 through the local interconnect: The line has been cleaned/clean-invalidated. Clean invalidates the line.
3. Return to Step 1 for the next line in the range if the address of the next line is less than the starting physical address + length.

---

**NOTE:** There is no difference between the clean and clean-invalidate flows.

---

---

**NOTE:** The PL310 auxiliary control register cannot be changed dynamically. L2 must be disabled, which requires flushing the buffers, etc. and then changing the register.

---

#### 4.3.5.1.3.2 Invalidate Flow

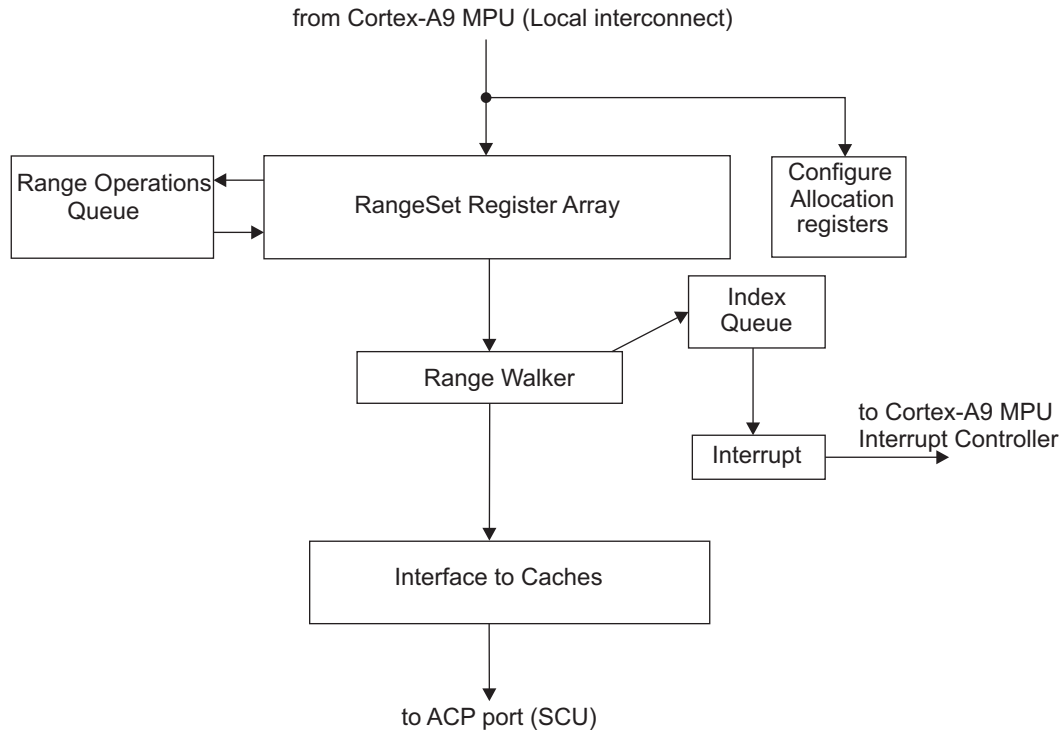

For an invalidate operation:

1. The CMU does an ACP write of all bytes. Data is set to 0.
2. This invalidates lines in L1 and L2; if it hit in L1 or L2, the write is sent to L3 by PL310. The local interconnect drops the write request and sends an OKAY response to the CMU.
3. If the address misses in L1 and L2, the PL310 sends the address to the local interconnect, which drops the write request and sends an OKAY response to the CMU.

### 4.3.5.2 Architecture

Figure 4-8 shows the major blocks of the CMU.

- Range Operations Queue: Queue of activated range sets
- RangeSet Register Array: Sets of registers holding the range sets
- Range Walker: Block that performs the operation
- Index Queue: Holds a queue of indices of the range set that needs to interrupt the CPUs

**Figure 4-8. Cache Maintenance Unit Blocks**

The Interface to Caches (see [Figure 4-8](#)) issues a request to no more than one cache line at a time.

#### 4.3.5.2.1 Range Sets

Each range operation is programmed into a set of range operation registers called a range set. The CMU has 64 range sets.

The CMU supports queuing of cache maintenance range operations. By enqueueing range sets, the programming interface is freed to allow programming of the next range set.

A range set has three registers that must be programmed to define the range set operation:

- The CMU Starting Address Register contains a 32-bit physical address ([CMUSTARTPA\\_i\[31:0\] STARTPA](#)).
- The CMU Length Register programs the length of a range in bytes ([CMULENGTH\\_i\[11:0\] LEN](#)). The value in this register must be the length of the data buffer minus 1 so that  $CMUSTARTPA + CMULENGTH$  is the address of the last byte within the range. Cache lines containing the starting address and every physical address up to and including  $CMUSTARTPA + CMULENGTH$  have the particular cache management operation (CMO) performed on them.
- The CMU Operation Register controls the operation performed and several other properties of the range set ([CMUOPERATION\\_i\[3:0\] OPNSEL](#)). The operations supported are clean, clean/invalidate, and invalidate. The write to set the operation register activates the range set. Once the range set is activated, software must not attempt to change any range set register.

[Figure 4-9](#) shows the relationship between the starting address and the length.

Figure 4-9. Start and Length of Range Set

mpu\_a9-011

Multiple range set may be programmed and will queue to execute. The programmer should not wait for previous range sets to complete before activating new range sets.

#### 4.3.5.2.2 Parallelism and Pipelining

The CMU can pipeline requests, thus achieving faster throughput on the execution of a range set operation.

The [CMUCONFIGREG\[10\] DISABLEPIPELINING](#) bit forces the interface to the caches to issue a request to no more than one cache line at a time. Depending on the particular interface to the caches, operations can normally be pipelined several cache lines deep by issuing operations against additional cache lines before earlier cache line requests are complete. The disable pipelining feature causes the CMU to perform the operations serially. When disable pipelining is enabled, the accesses are sent as strongly ordered accesses; this ensures that accesses are not pipelined. This feature detects bad addresses that have been programmed in the CMU, because this address goes to the local interconnect block, which then detects the bad addresses. Setting disable pipelining makes the CMU ineffective. Therefore, disable pipelining must be used only for debug purposes when bad address programming is suspected.

In addition, the CMU can process more than one range-set operation in parallel. Multithreading can occur through time-multiplexing or pipelining the operation of more than one range operation so that they occur at least partially in parallel. The [CMUOPERATION\\_i\[8\] WAIT](#) bit indicates that this range operation must not be started until all previously activated operations complete (wait does not affect allocated operations, only activated operations). Thus, the WAIT bit prevents a range operation from being threaded in parallel with any range operation activated earlier.

#### 4.3.5.2.3 Completion Handling

Completion of the handling of a range-set operation leaves it in completed state or error state. The completion handling option for a range set is programmed in the [CMUOPERATION\\_i\[10:9\] COMPLETION](#) bit field. No interrupt is sent if the [CMUCONFIGREG\[8\] INTEN](#) is set to 0.

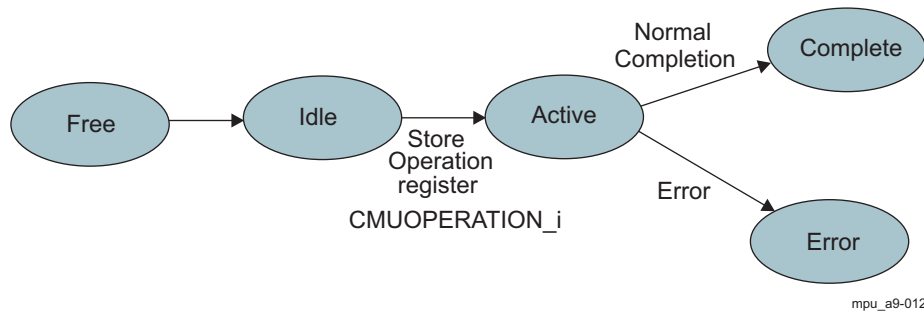

Anytime a normal or error completion generates an interrupt (or would, but  $INTEN = 0$ ), the INDEX, ERROR, and VALID bits of the [CMUINTRACK](#) register of the range set is put into the interrupt index queue of the CMU FIFO. If the FIFO is already full and  $INTEN = 1$ , the CMU suspends the processing of range sets until the completion can be recorded in the range set. If the FIFO is already full and  $INTEN = 0$ , the newest completion is lost and not recorded in the FIFO.

Normal completion is not signaled until any writes generated by clean operations have reached the point where they can be seen by all masters in the device, usually the main memory.

Figure 4-10 shows the states a range set can take:

- Free: Range set is available.
- Idle: Range set has been allocated or reserved by software, but not yet activated.
- Active: Range set has been activated.
- Complete: Range set completed normally.
- Error: Range set completed with an error.

**Figure 4-10. Range Set States**

#### 4.3.5.2.4 Allocation

To allocate a range set, software reads the allocation register ([CMUALLOCATE](#)). This register returns the index of a free range set (in free state). If there are no free range sets, the register returns with the NONE bit set ([CMUALLOCATE](#)[31] NONE = 0x1). The range set that is allocated is moved to idle state and is not available for allocation.

To return a range set to free state, software that has processed the completion must write the range set index to the deallocation register ([CMUDEALLOCATE](#)[7:0] INDEX). If software does not deallocate range sets, the pool of free range sets is exhausted and allocation fails.

This allocation and deallocation scheme places all mutual exclusion into the allocation hardware where it can be made atomic.

The number of allocations is the total number of range sets minus 8.

#### 4.3.5.3 Address Sequence Generation

The CMU generates a sequence of addresses according to the programmed quantities in a range set. The addresses generated are always aligned to the LINESTEP size.

Because the length register ([CMULENGTH\\_i](#)) encodes the range length (1 byte), the minimum length that can be encoded is 1 byte (encoded as 0 in the length field: [CMULENGTH\\_i](#)[11:0] LEN = 0x0).

The first address issued is always the StartingPA ([CMUSTARTPA\\_i](#)[31:0] STARTPA) aligned to the beginning of the cache line.

After each cache line step, the working address is incremented by the LINESTEP size (32 bytes). If the new working address is greater than [CMUSTARTPA\\_i](#) + [CMULENGTH\\_i](#), the operation is complete. Otherwise, the operation is performed using the new working address and execution loops to perform the next cache line step.

#### 4.3.5.4 Using the CMU

To use the CMU:

1. Allocate a range set.
2. Store StartPA and length.
3. Activate by storing the operation register.

4. Monitor for completion through an interrupt (preferred) or polling.
5. Free range set.

[Section 4.3.5.4.6](#) explains how to use the CMU with paged memory so that a single buffer can span the divide between pages and large buffers that are more than 4KB in length.

---

**NOTE:** It is important to follow the previous sequence. Otherwise, interconnect response errors can occur. For example, trying to free a range set before it completes (with or without error) can lead to an interconnect response error. Writing to a range that is not free (which is really IDLE, because free goes to IDLE after successful allocation) also leads to interconnect response errors.

---

It is not necessary to enable interrupts on all range sets. For example, if five ranges are enabled, then interrupt can be enabled for only the last range set (assuming range sets 0, 1, 2, 3, and 4 were activated in that order [0 first, 1 next, etc.]). Then, when interrupt is enabled for range set 4, range sets 0, 1, 2, and 3 are assured to be complete. However, it is still recommended to read the status of range sets 0, 1, 2, and 3 to ensure they are complete and without errors, before concluding that range sets 0 to 4 are complete.

#### 4.3.5.4.1 Allocating a Range Set

Software may attempt to allocate a range set by reading from the CMU allocation register ([CMUALLOCATE](#)). If the returned value is positive, it is the index of a range set that has been allocated by this read. The allocated range set is not eligible for allocation again until it is freed. The allocation register makes mutual exclusion unnecessary for choosing and programming a range set.

If the value returned by the allocation register is 1 (the [CMUALLOCATE\[31\]](#) NONE bit), no range set can be allocated. Software must wait to allow processing that can free a range set to complete before retrying the allocation.

The number of allocations is 56.

#### 4.3.5.4.2 Storing Starting Physical Address and Length

The first store into a range set must be to the [CMUSTARTPA\\_i\[31:0\]](#) STARTPA bit field.

The STARTPA is the lowest physical address in the range (the smallest value in unsigned arithmetic). It is a 32-bit byte address. There are no address alignment constraints because the range walker masks the generated addresses so that each cache operation is performed to the lowest address in a cache line.

The [CMULENGTH\\_i\[11:0\]](#) LEN bit field is defined to be the difference between the STARTPA and the byte of the range with the highest value (using unsigned arithmetic). This is the size of the range minus 1. The byte addressed by STARTPA + LEN is within the range. The largest range size is 4KB.

#### 4.3.5.4.3 Activate the Range Set by Storing the Operation Register

A range set is activated when its operation register is stored. This register is programmed with the cache operation ([CMUOPERATION\\_i](#)), whether to interrupt on completion, and other controls.

The registers of a range set are not writable unless they are in IDLE state. This must be enforced in software; otherwise, an interconnect response error occurs.

A range set cannot be deallocated unless it is in COMPLETE or ERROR state. This also must be enforced in software; otherwise, an interconnect response error occurs.

#### 4.3.5.4.4 Monitoring Completion

Two ways to monitor for completion are:

- Polling: To monitor for completion with polling, the status register [CMUSTATUSREG\[0\]](#) BUSY can be read to determine whether any range sets are still in operation, if wanting to wait for all range sets to complete, or poll the [CMURANGESTATE\\_i\[31:29\]](#) STATE bit field to watch for a particular range set to move to COMPLETE or ERROR state. These states indicate that the range operation completed

normally or stopped because of an error, respectively.

- **Interrupt:** To monitor for completion with interrupt, the [CMUOPERATION\\_i\[10:9\]](#) COMPLETION bit field must be set to interrupt on completion. The interrupt handler must read the [CMUINTRACK\\_NS\[11:0\]](#) INDEX bit field to get the range set index of the interrupt-generating cache operation. The status of the completed operation can be read from the range set, particularly the [CMURANGESTATE\\_i\[31:29\]](#) STATE bit field.

#### 4.3.5.4.5 Freeing a Range Set

When a range set operation completes and software is done examining the completion information, the range set must be freed to allow it to be reallocated. To free a range set, write its index to the [CMUDEALLOCATE\[7:0\]](#) INDEX bit field.

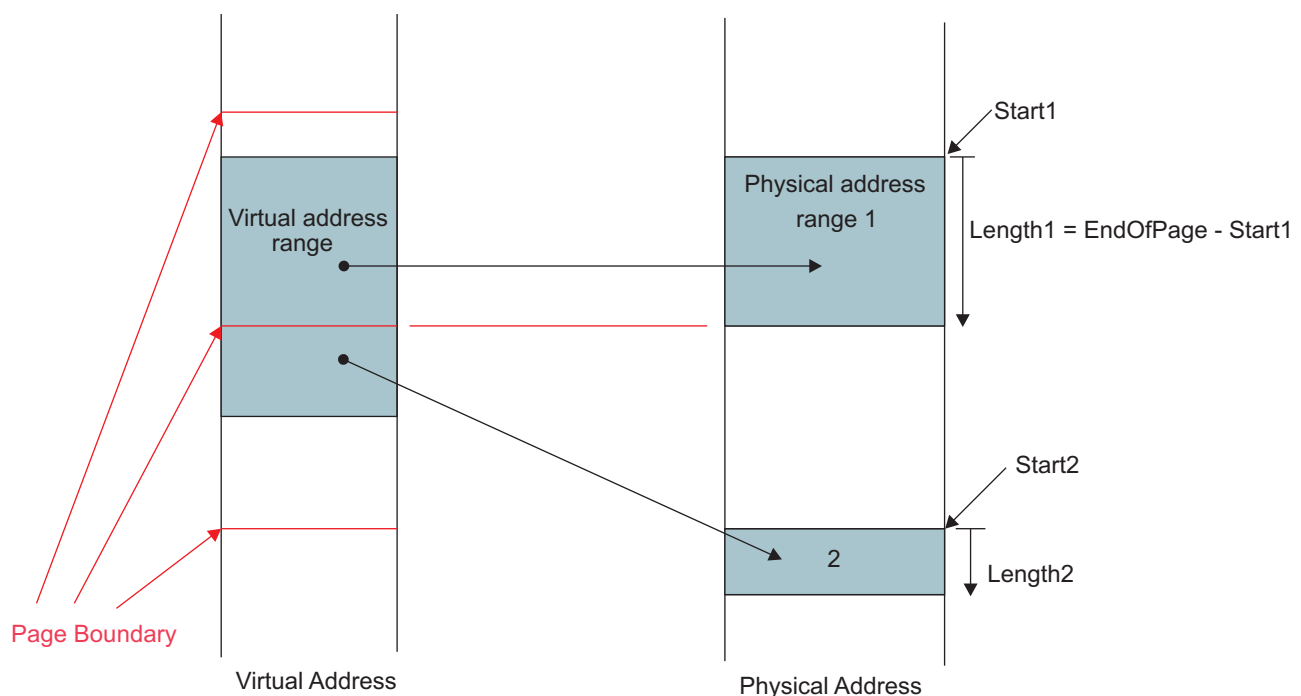

#### 4.3.5.4.6 Paged Memory

Any range more than 1-byte long may span a page boundary. The page mappings for contiguous virtual memory pages may not be contiguous in physical memory. Ranges must end when a page boundary is encountered so each page of the range can be translated separately to physical memory. The software must perform the page mapping (possibly using ARM CP15 operations for that purpose) to produce the physical address needed to program the CMU.

In a paged environment, even a small buffer may cross a page boundary and require two range operations to cover the two parts of the buffer. Two range sets must be used to program the two ranges, each wholly contained within a page.

[Figure 4-11](#) shows this scenario.

**Figure 4-11. Range in Paged Virtual Memory**

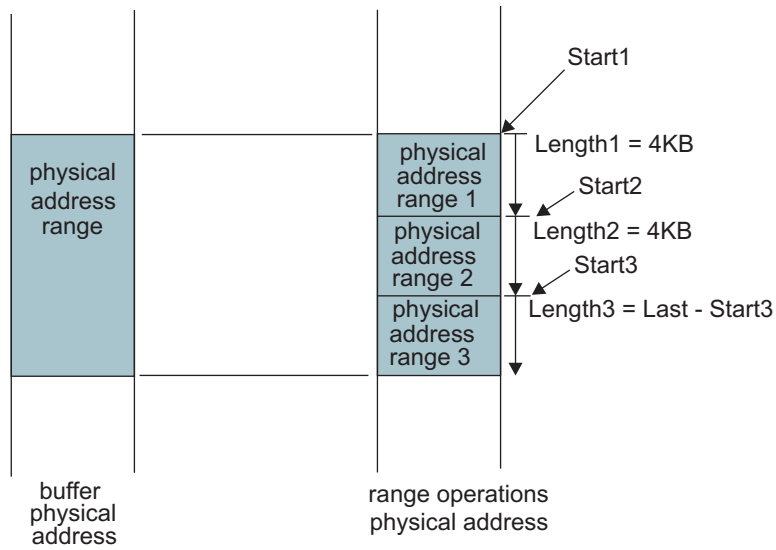

mpu\_a9-016

#### 4.3.5.4.7 Large Buffers

Even when a buffer is contiguous in physical memory it may be large enough that it cannot be contained within a range set, because the length is restricted to 4KB.

[Figure 4-12](#) shows the large buffer in physical memory.

Figure 4-12. Large Buffer in Physical Memory

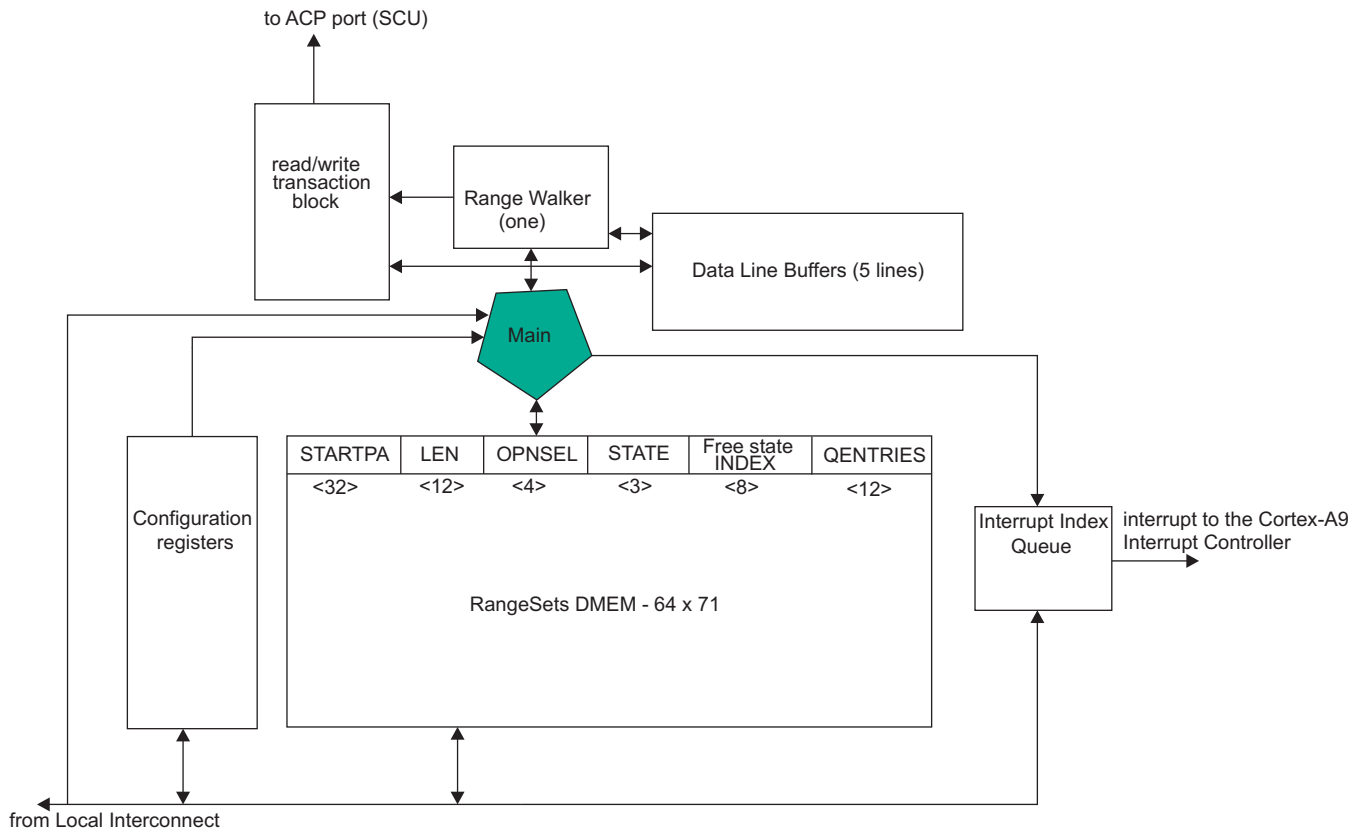

mpu\_a9-013

#### 4.3.5.5 Micro-Architecture of CMU

Different range sets can be activated by different masters; therefore, no assumptions must be made regarding the atomicity of range set register programming. The Start PA, length, and operation registers from multiple masters can be interleaved. Multiple range sets can be allocated to different masters and activation of them can be out of order.

Figure 4-13 shows the CMU micro-architecture.

**Figure 4-13. CMU Micro-Architecture**

mpu\_a9-014

#### 4.3.5.5.1 Range Set DMEM

This memory has 64 rows and each row is 71 bits wide.

#### 4.3.5.5.2 Data Line Buffers

The data line buffers hold the read data for the ACP reads that hit in L1 or L2 for clean/clean-invalidate operations. Each line is 32 bytes with a 64-bit interface from ACP. To maintain an optimal throughput, the Cortex-A9 MPU, which has a single range walker, needs at least four line buffers (five line buffers are available).

#### 4.3.5.5.3 Range Walker

The range walker is the block that steps through line steps using STARTPA until reaching STARTPA + LEN. The range walker gets two indices from main control that it uses to access range sets DMEM to get STARTPA, LEN, etc., and then interacts with the read/write transaction block. This block issues ACP reads, ACP writes, etc. for the range.

#### 4.3.5.5.4 Main Control

This is the main controller that coordinates between the various blocks and resolves arbitration conflicts for access to the DMEMs and maintains the free state indices and operation queue pointers.

#### 4.3.5.5.5 Interrupt Index Queue

The Interrupt index queue holds the index of the range set whose operation register `CMUOPERATION_i` indicates "interrupt on completion." The size is constant and is four entries.

### 4.3.5.5.6 Configuration Registers

This block holds all the common configuration registers, such as [CMUALLOCATE](#), [CMUDEALLOCATE](#), and others.

### 4.3.5.5.7 Read/Write Transaction Block

This is the block that creates the read/write transactions from the range walker into SCU-compatible protocol.

## 4.3.5.6 Free Set Management, Operation Queue Functionality, and Main Control

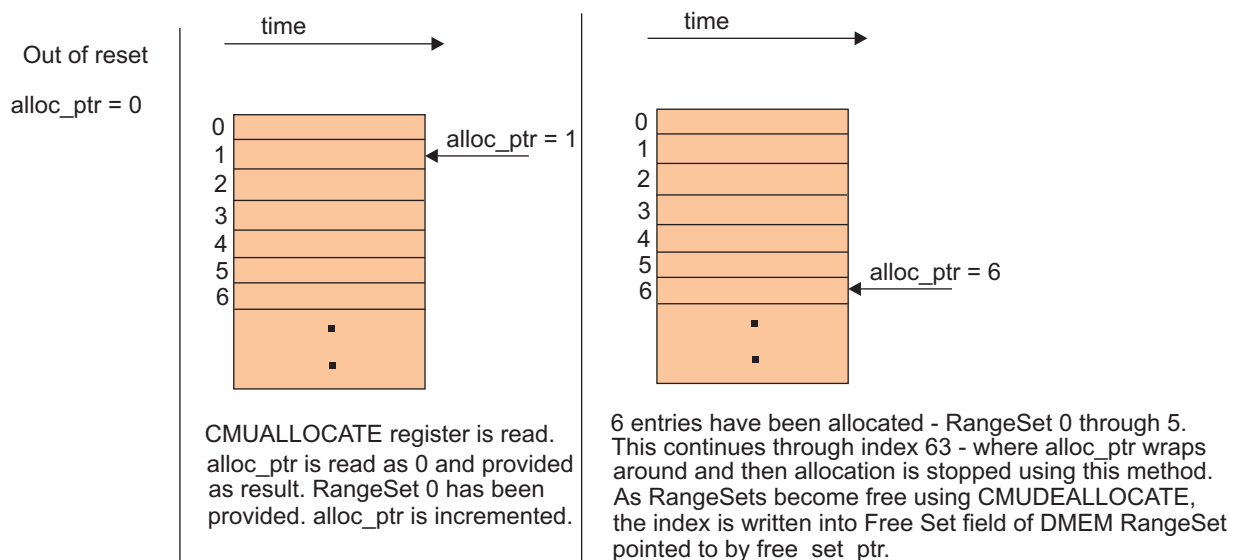

### 4.3.5.6.1 Allocation and Free Set Management

Using the CMU, the first step to enabling a range set is to read the [CMUALLOCATE](#) register. This returns the index of a range set that is in free state. Detecting a free range set is done in the following two ways.

#### 4.3.5.6.1.1 Out of Reset

Two pointers are maintained in main control, `alloc_ptr` and `active_ptr`. Both are 0 out of reset. When the [CMUALLOCATE](#) register is read, the value of `alloc_ptr` is returned and then incremented. This continues until `alloc_ptr` wraps around, which happens when all 64 range sets have been allocated (see [Figure 4-14](#)).

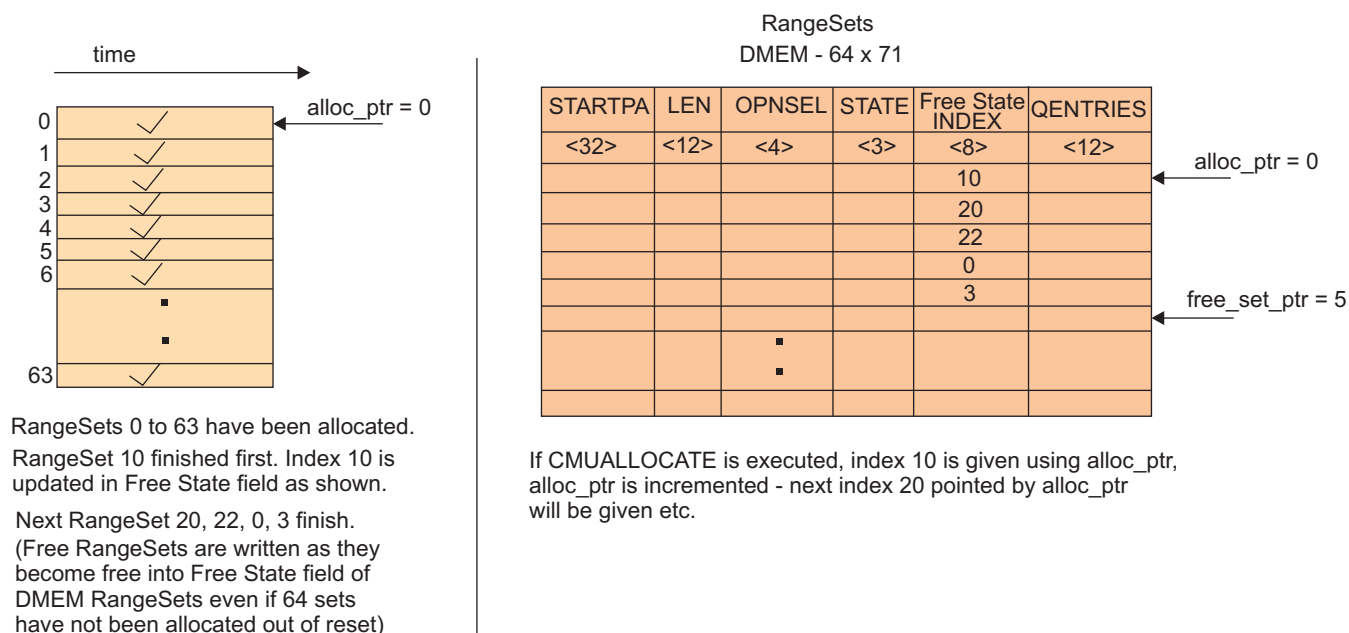

Figure 4-14. Free Set Allocation out of Reset

mpu\_a9-015

#### 4.3.5.6.1.2 Steady State – Once alloc\_ptr Has Wrapped Around

Once `alloc_ptr` has wrapped around, allocation cannot be based on the out-of-reset way. Allocations must be based on range sets that are free. Range sets can be activated in an order that differs from what was allocated. Software can program activations out of order with respect to allocations. This can happen naturally when there are multiple masters. When the [CMUDEALLOCATE](#) register is written, the index pointed to by the register contents is freed. This index is written into the free state INDEX field of the range set DMEM, as pointed to by `free_set_ptr`, which is then incremented (see [Figure 4-15](#)).

**Figure 4-15. Allocation in Steady State**

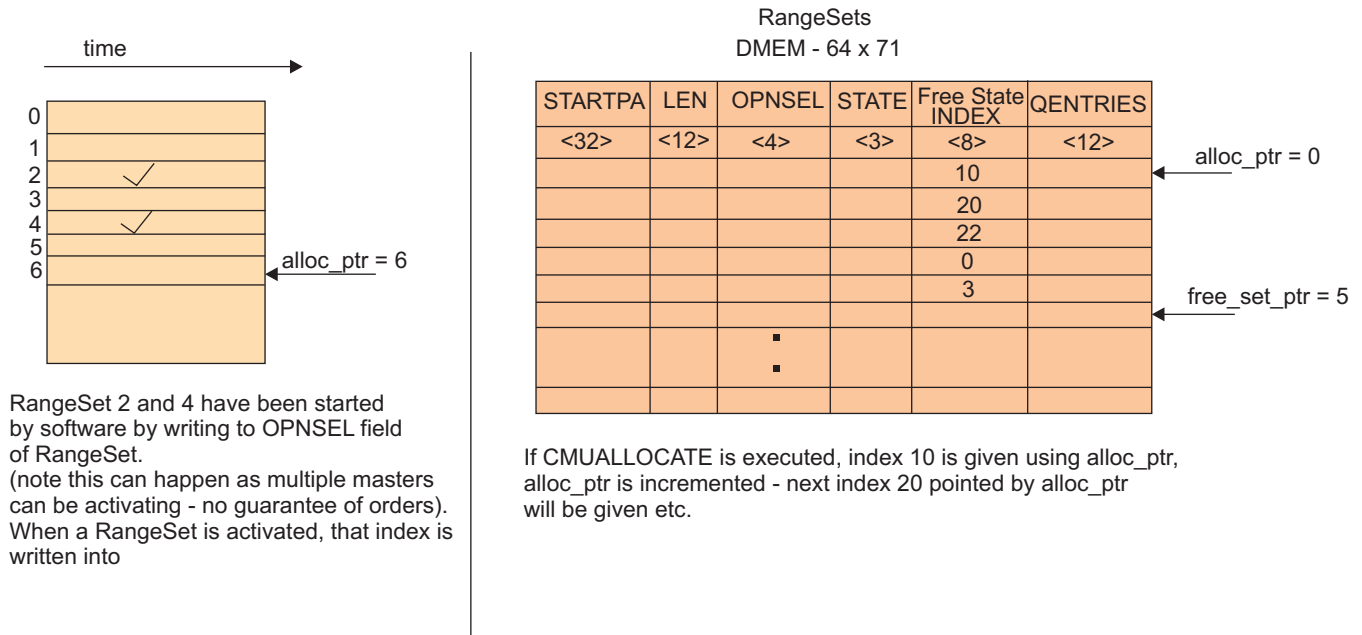

mpu\_a9-017

The check mark in each index indicates that the index has been allocated. Figure 4-15 shows a state where all 64 range sets have been allocated. Assume various range sets have been activated. Now, assume that range set 10 becomes free first when software writes to the **CMUDEALLOCATE** register with index 10. Index 10 is written into the Free State field as pointed to by free\_set\_ptr, which is 0 out of reset. Next, range sets 20, 22, 0, and 3 are freed. free\_set\_ptr points to entry 5 as the next entry to be updated when the **CMUDEALLOCATE** register is written. When a **CMUALLOCATE** register is read, the DMEM entry pointed to by alloc\_ptr is read. The contents of the Free Set field are read (10 is returned to **CMUALLOCATE** register read). alloc\_ptr is then incremented.

#### 4.3.5.6.2 Activation and Operation Queue Functionality

The operation queue stores the indices of the range sets that have been activated. When CMUOPERATION is stored that particular index is activated. The activated index is written into the operation queue (QENTRIES) field of DMEM RangeSets to the address pointed to by active\_ptr, which is 0 out of reset (see Figure 4-16).

Figure 4-16. Operation Queue Functionality

mpu\_a9-018

4.3.5.6.3 Main Control

These pointers are maintained in main control, which is made aware of the range walker. The main control block distributes active\_ptr to the range walker. The range walker needs two active\_ptr pointers for optimal throughput.

4.3.5.7 Priority of Range Set DMEM Accesses

The following must be the priority of DMEM accesses, from highest to lowest:

- 1. Interconnect configuration accesses to range sets: Programming range sets, CMUALLOCATE, CMUDEALLOCATE, etc.
- 2. Range walker access to read range sets and update range set state

Range walker access to read range sets and update states should be less frequent than configuration access. Once the range set is activated, all information necessary for performing operations is kept in local registers.

4.3.5.8 Interrupt Index Queue

When the CMUCONFIGREG\_i[8] INTEN bit is set to 1, and if the CMUOPERATION\_j[10:9] COMPLETION bit field is configured for interrupt, the index for the completed range set is placed in the interrupt index queue and the CMUINTRACK register is prepared before the interrupt is raised.

Software can read the CMUINTRACK[31] VALID bit and execute the ISR. Once software reads the CMUINTRACK register, the next valid index in the interrupt index queue is updated in the CMUINTRACK register, which software reads after it performs the ISR for the first index. If the VALID bit is 0, because no more entries are in the interrupt index queue, software exits the ISR processing. Hardware also disables the interrupt.

Thus, using one interrupt, ISR for multiple indices can be handled at one time.

The interrupt index queue has only the index and is maintained by pointers.

4.3.5.9 Important Programming Notes for Users of CMU

For optimal performance, software must do the following:

- The CMUCONFIGREG\_i[10] DISABLEPIPELINING and CMUCONFIGREG\_i[9] DISABLEPARALLEL bits must be set to 0. These come out of reset as 1, and if not set to 0, they serialize the operation of the CMU and reduce throughput significantly. Disable pipelining must be set to 0 for proper operation and should be used only when bad address programming is suspected; if this bit is set to 1, the CMU will not work.
- The CMUCONFIGREG\_i register must be programmed at the beginning or when the CMU is idle. The CMUCONFIGREG\_i[3] ENNSWR bit (enable NS write) must be set appropriately so that non-safe programs can write or not write to this register.
- All CMU writes must be done as device writes; otherwise, they are combined in the Cortex-A9 MPU and can become a burst write access, which the local interconnect does not have the logic to split.

---

**NOTE:** All interconnect write response errors are imprecise errors when writes are device writes, because they are a bufferable type in PL310. If precise errors are required, writes must be done as strongly ordered writes; however, these are slow and thus should be avoided. Because writes that encounter errors do not occur in the CMU, the effect of imprecise errors is that later instructions to the CMU that depend on earlier writes (that may have encountered an error) would have occurred. Because no such sequences are in the CMU, it should be okay to use device stores. Sequences do exist, however, where [CMUALLOCATE](#) read is done and if the read is successful, then a write to RangeSet occurs. However, [CMUALLOCATE](#) is a read followed by writes and read errors are always precise. CMUDELLOACTE is a write that may not happen (because of a software error, such as trying to deallocate something that is not complete or if the NS = 1 program is trying to deallocate an NS = 0 RangeSet). Subsequent writes to range sets, however, are protected by a read in between by [CMUALLOCATE](#).

---

- All CMU reads must be done as device reads.
- Writes to range sets must be done only when [CMUALLOCATE](#) read returns a valid range set ([CMUALLOCATE](#)); otherwise, an interconnect response error results.
- Writes to free a range set by a DEALLOCATE write must be done only after the status is examined to ensure that the range set is complete (with or without error); otherwise, an interconnect response error ([CMUDEALLOCATE](#)) results.
- It is preferable to use interrupt processing rather than polling to determine whether a range set is complete.

#### 4.3.5.10 Notes on Corner Cases – Hardware and Software Notes

- When the ACP performs a read of a line, for example in L1, it uses that data to perform an ACP write for clean/clean-invalidate. If the CPU modifies the data between the ACP read and ACP write, the CPU write is lost. The ACP/CMU has no way to detect this. Semaphores must be used to ensure that the CMU clean/clean-invalidate is started only after the CPU updates the buffer.
- The Cortex-A9 CPUs support prefetching and speculative caching of data into L1 and L2 caches. While CMU operations are in progress, Cortex-A9 may prefetch the data back into L1 and L2 after it has been invalidated; this may be because addresses close to the invalidated range were touched by the CPU. An external master may have updated the address that has been invalidated and for the CPU to see the updated state, the speculatively filled address must be invalidated out of L1/L2. This can be done as an invalidation of the L1/L2 address range just before fetching the updated buffer. Care should be taken to ensure that the CPU is not working on addresses being operated on the CMU.
- CMU data is always dirty; therefore, when data is clean in L1/L2, it still is written to external memory because the CMU data looks like the most recent write to dirty the clean data in L1/L2. Therefore, software must not attempt to start the consumer to consume the data until after the CMU operation has completed a clean or clean-invalidate range.
- Because all of the bytes of the cache lines at the beginning and end of a range are affected by cache maintenance, software must insure that this does not cause unintended effects. The most general solution is to allocate buffers that may be subject to cache maintenance so that they are aligned to a cache line boundary (32 bytes on this device, but for compatibility with old and future devices, 64-byte alignment is suggested). This will prevent unrelated data from sharing a cache line with the beginning of the buffer. In addition, the end of the buffer allocation should also be padded to a cache line

boundary so that no unrelated data shares the final cache line of the buffer.

- The CMU does not handle wrap-around from a high physical address to a low physical address. Software must not program a CMU range set with a starting address and length that exceeds  $2^{32} - 1$ . Such a range must be broken into parts so that no single range set is programmed to cross this boundary.

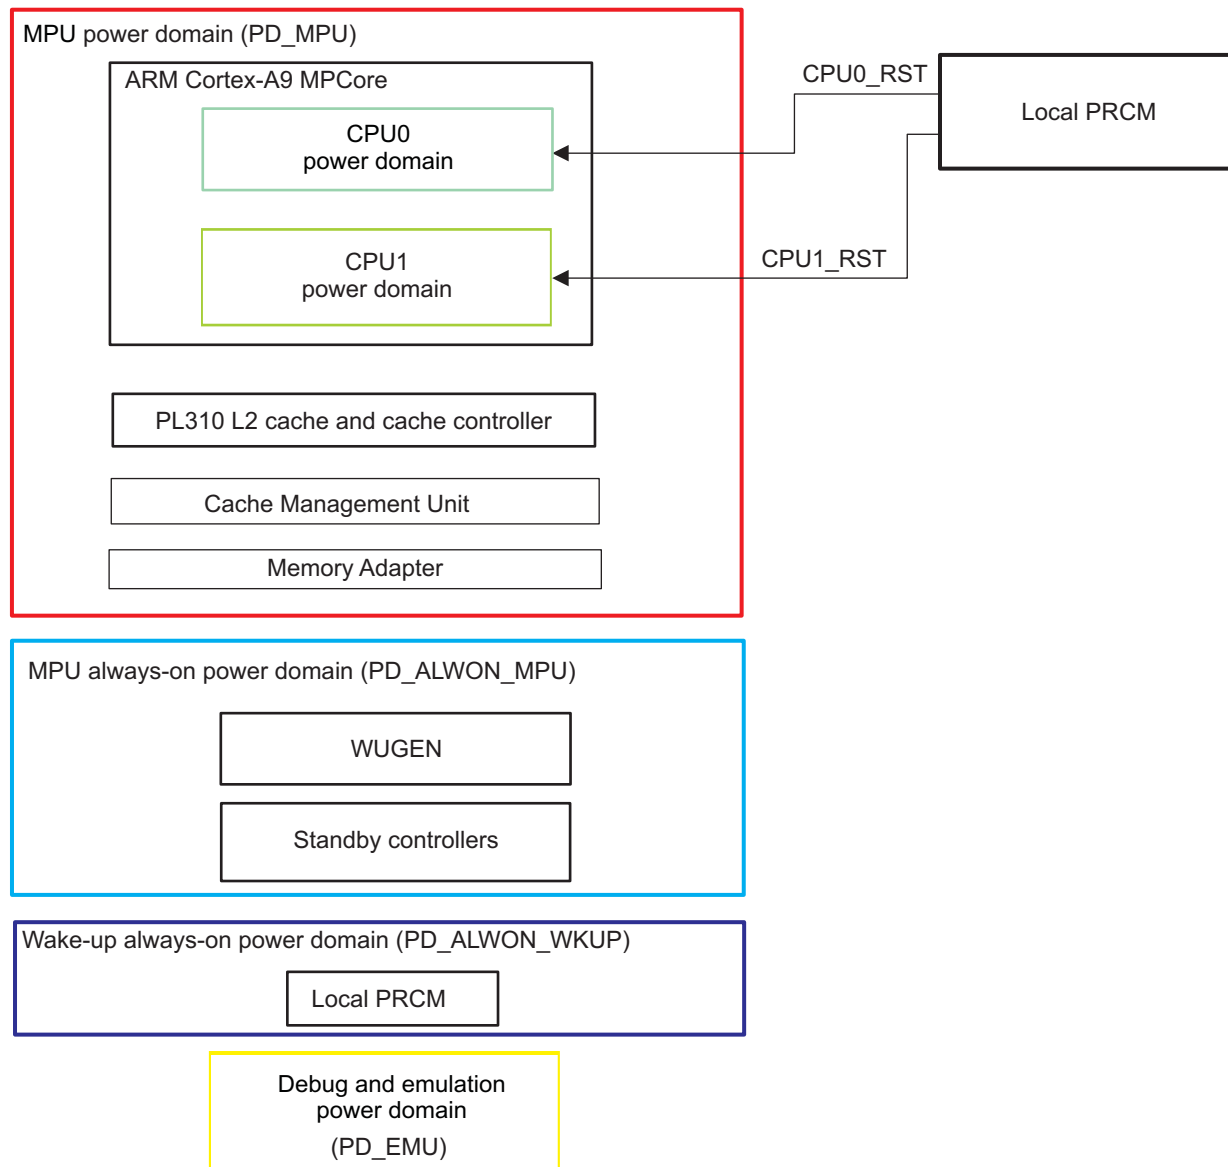

#### 4.3.6 Power Management

- The Cortex-A9 MPU subsystem implemented a local PRCM module to handle the local CPU power domain.
- Support cache retention
- The Cortex-A9 MPU subsystem has six power domains.
- The local PRCM module handles the power management in conjunction with the global PRCM. The local PRCM module has its own registers and is clocked by the system clock, which is the same as the global PRCM.

##### 4.3.6.1 Power Domains

The Cortex-A9 MPU subsystem is divided into six power domains controlled by the local or global PRCM module, as shown in [Figure 4-17](#).

**Figure 4-17. Cortex-A9 MPU Subsystem Power Domain Overview**

mpu\_a9-005

The CPU power domains (CPU0 and CPU1) and L1 cache are controlled by the local PRCM module. The system and emulation power domains (PD\_MPU and PD\_EMU) are controlled by the global PRCM. The power-management support for debug and emulation is distributed between the local and global PRCM modules.

The Cortex-A9 local PRCM module includes two PSCON modules to control the power chains for CPU0 and CPU1. The [PRM\\_PSCON\\_COUNT](#) register is used for that control purpose.

To maximize performance and SMP scalability, both CPUs must run at the same frequency. Do not lower the frequency of one CPU as a power-saving option.

The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross-reference to the different voltage domains.

For information about the physical power domains (PD\_MPU, PD\_EMU, and PD\_ALWON\_MPU) and the related voltage domains, see [Chapter 3, Power, Reset, and Clock Management](#).

### 4.3.6.2 Power States of CPU0 and CPU1

CPU<sub>x</sub> (where x = 0 or 1) changes power states only when the StandbyWFI signal is asserted. The user can check this in the [WKG\\_CONTROL\\_0/WKG\\_CONTROL\\_1](#)[8] STANDBYWFI bit. In conjunction with StandbyWFI, the CPU power state transition is also based on the SCU CPU Power Status register, which software must program before executing the wait for interrupt (WFI) instruction.

Each CPU clock can be gated independently. This clock gating is controlled by several hardware and software conditions.

Clock transition depends on the StandbyWFI assertion + the value of 3 bit fields:

- PWRCTLO from the SCU power status register (internal to ARM)
- CLKTRCTRL from the [CM\\_PDA\\_CPUi\\_CLKSTCTRL](#) register (local PRCM module)
- POWERSTATE from the [PM\\_PDA\\_CPUi\\_PWRSTCTRL](#) register (local PRCM module)

The power states of both CPUs do not have to be the same. The power state of CPU<sub>x</sub> can be:

- Normal (run) mode
- Dormant mode
- Power-off mode

[Table 4-5](#) gives details of the power state of the supported CPU<sub>x</sub> and the corresponding values of the local PRCM register.

**Table 4-5. CPU<sub>x</sub> Supported Power States**

Hardware Conditions		CPU <sub>x</sub> Programming Model				Resulting CPU <sub>x</sub> State			
StandbyWFI StandbyWFE	SCU CPU <sub>x</sub> Power Status	Local PRCM Power State <a href="#">PM_PDA_CPUi_PWRSTCTRL</a> [ 1:0] POWERSTATE	Local PRCM Logic Retention State <a href="#">PM_PDA_CPUi_PWRSTCTRL</a> [ 2] LOGICRETSTA TE	Local PRCM L1 Cache Memory Retention State <a href="#">PM_PDA_CPUi_PWRSTCTRL</a> [8] L1_BANK_RET STATE	Local PRCM Clock Transition Control <a href="#">CM_PDA_CPUi_CLKSTCTRL</a> [ 1:0] CLKTRCTRL	Logic	L1 Cache	ARM Cortex- A9 Internal Clock Gating	Power State at Local PRCM
CPU <sub>x</sub> running <sup>(1)</sup>	Any	Any	Any	Any	Any	ON	ON	ON	ON
CPU <sub>x</sub> in WFE <sup>(2)</sup>	Any	Any	Any	Any	Any	ON	ON	OFF	ON
CPU <sub>x</sub> in WFI	Normal	Any	Any	Any	NO_SLEEP/SW _WKUP	ON	ON	OFF	ON
		ON	Any	Any	HW_AUTO	ON	ON	OFF	ON
		INACTIVE	Any	Any	HW_AUTO	ON	ON	OFF	INACTIV E
CPU <sub>x</sub> in WFI	Dorman t	RETENTION	Open switch retention (OSW)	RETENTION	HW_AUTO	OFF	RET	OFF	Open switch retention
CPU <sub>x</sub> in WFI	Power off	OFF	Any	Any	HW_AUTO	OFF	OFF	OFF	OFF

<sup>(1)</sup> When CPU<sub>x</sub> is running, no power transition is possible.

<sup>(2)</sup> When CPU<sub>x</sub> is in WFE mode, no power transition is possible.

The [PM\\_PDA\\_CPUi\\_PWRSTCTRL](#) register is static over any power transition. That is, software programs it before executing the WFI instruction and does not change it until CPU<sub>x</sub> is again in running mode. In other words, when CPU<sub>x</sub> reaches a low-power state (DORMANT, POWER OFF), it cannot move to another low-power state. It must be woken up to reach another low-power state. To wake up CPU<sub>x</sub>, the user must:

1. Execute a forced wake-up transition to the CPU<sub>x</sub>: [CM\\_PDA\\_CPUx\\_CLKSTCTRL](#)[1:0] CLKTRCTRL = 0x2.
2. The CPU<sub>x</sub> interrupt handler must set back the automatic hardware transition [CM\\_PDA\\_CPUx\\_CLKSTCTRL](#)[1:0] CLKTRCTRL = 0x3.

The MPU subsystem power domain (PD\_MPU) must be at a higher or equal power state (state that consumes more power) than the higher of the two CPUs. For example, it is illegal for the MPU subsystem power state to be OFF, while the power state of one or both of the CPUs is DORMANT. Software must ensure that only legal power states are programmed. When an illegal state is entered, the behavior of the hardware is unpredictable. Do not program the Cortex-A9 MPU in CSWRET, L2\$ in OFF, or either or both CPUs in CSWRET.

For coherency, software must ensure that both CPUs are in the Running/ON or WFI/ON state.

Table 4-6 lists the available CPU power states in single and coherency mode.

**Table 4-6. Available CPU Power States in Single and Coherency Mode**

CPU0 Power State	CPU1 Power State	Mode
Running/ON or WFI/ON	Running/ON or WFI/ON	SMP mode (coherent mode)
Running/ON or WFI/ON	OFF	Single mode (CPU1 is out of coherency)
WFI/INACT	OFF	
WFI/OSWRET	OFF	
WFI/OFF	OFF	

Table 4-7 lists the MPU power states handled by the local and global PRCM.

**Table 4-7. MPU Power States Handled by the Local and Global (Device) PRCM Modules**

CPU State at Local PRCM	PRCM Power State	Logic Retention State	L2 Cache Memory Retention State	PRCM Clock Control	Logic Resulting State	L2 Cache Memory Resulting State	DPLL Clock	MPU Power State at PRCM
At least one is ON	Any	Any	Any	Any	ON	ON	ON	ON
Power state of both CPUs are INACTIVE, CSWR or OSWR	Any	Any	Any	No sleep/software wakeup	ON	ON	ON	ON
	ON	Any	Any	Hardware auto	ON	ON	OFF	ON
	INACTIVE	Any	Any	Hardware auto	ON	ON	OFF	INACTIVE
	RETENTION	CSW	RETENTION	Hardware auto	ON	RETENTION	OFF	CSWRET
	RETENTION	OSW	RETENTION	Hardware auto	OFF	RETENTION	OFF	OSWRET
RETENTION	OSW	OFF	OFF	Hardware auto	OFF	OFF	OFF	OSWRET
Power state of both CPUs is OFF	OFF	Any	Any	Hardware auto	OFF	OFF	OFF	OFF

WFI: State where logic is closed switch, memory is ON, and clock is gated off

DORMANT (for CPU0 or CPU1): State where logic is in opened or closed switch (depending on programming value), memory is in RETENTION, and clock is gated off

ON/OFF (for system logic): State where logic is in opened or closed switch, depending on whether the higher of the two CPU power states is opened or closed switch. For example, if CPU0 is in opened switch dormant mode and CPU1 is in closed switch dormant mode, system logic must be closed switch.

When the Cortex-A9 MPU reaches a low-power state (INACT, CSWRET, OSWRET, OFF), it cannot move to another low-power state. It must be woken up to reach another low-power state.

For the CPU0 and CPU1 power states and power state transitions, see the ARM Cortex-A9 MPCore TRM (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

### 4.3.6.3 WUGEN

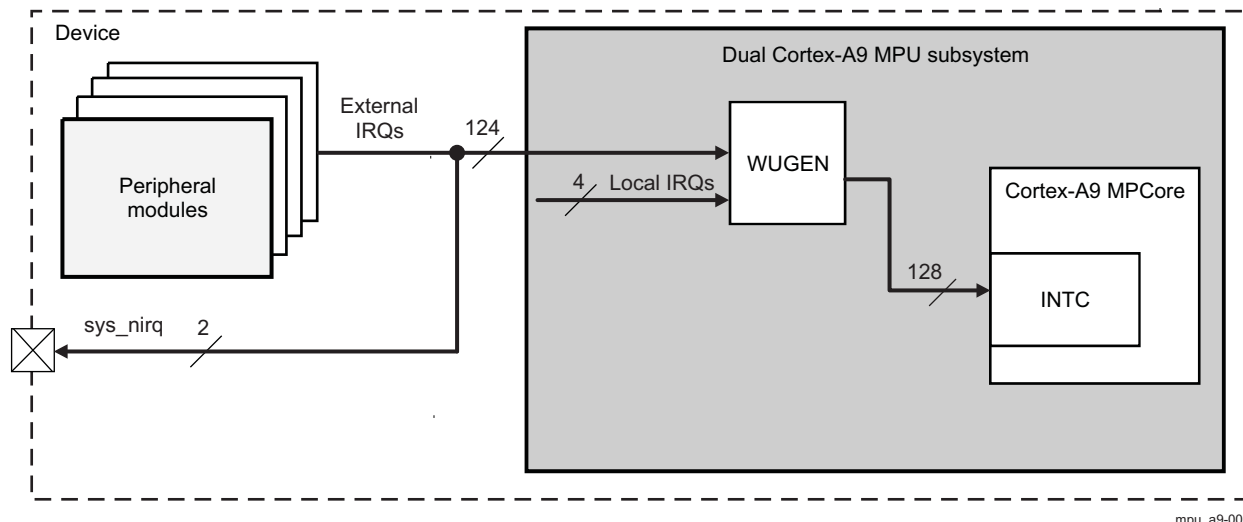

The WUGEN belongs to the MPU always-on power domain (PD\_ALWON\_MPU) and is responsible for generating wake-up events from the incoming interrupts (external and local) according to the enabled bits in the WUGEN registers.

The WUGEN unit has a 128-bit enable field (from [WKG\\_ENB\\_A\\_0](#) to [WKG\\_ENB\\_D\\_0](#) for CPU0 and from [WKG\\_ENB\\_A\\_1](#) to [WKG\\_ENB\\_D\\_1](#) for CPU1) which defines the interrupt that wakes up the corresponding CPU. The enable bits are reset to 0 and can be set to 1 to enable the interrupt to wake up the CPU. All interrupts are enabled after reset, except MA\_IRQ\_8 (which is not supported by the GP device). The Cortex-A9 MPU can access the WUGEN internal configuration registers through the local interconnect.

Software must program interrupt enabling and disabling coherently in the INTC and in the WUGEN enable registers. That is, a given interrupt for a given CPU is either enabled at both INTC and WUGEN, or disabled at both; no combination is allowed.

Figure 4-18 is a functional overview of the WUGEN in the Cortex-A9 MPU subsystem.

Figure 4-18. Cortex-A9 MPU Subsystem WUGEN

WUGEN includes two registers ([AUX\\_CORE\\_BOOT\\_0](#) and [AUX\\_CORE\\_BOOT\\_1](#)) that can be used by the ROM code and OS during SMP boot. The [AUX\\_CORE\\_BOOT\\_0](#) register is intended to indicate boot status to CPU1, the second core (also known as aux core); the [AUX\\_CORE\\_BOOT\\_1](#) register can be used to store execution start address of the CPU1.

For more information, see [Section 27.4.4, Startup and Configuration](#) in [Chapter 27, Initialization](#).

### 4.3.6.4 Power Transition Sequence

The three types of power transition sequences are:

- Power transitions that do not involve the local or global PRCM module  
When the CPU enters WFI state, provided the CPU power is not shut down or the DPLL is not gated off, the Cortex-A9 internally gates off the CPU clock and no action is required by local or global PRCM module. When an (enabled) interrupt is received, the Cortex-A9 exits WFI state.
- Power transitions handled by the local PRCM module  
When the CPU enters DORMANT or OFF states, the local PRCM module must participate to perform the power sequencing. If the system power domain remains ON and the DPLL is not gated off, the global PRCM module is not needed. To enable and control the CPU domain power mode transitions, write in the [CM\\_PDA\\_CPUi\\_CLKCTRL\[1:0\]](#) CLKTRCTRL bit field.
- Power transitions handled by the local and global PRCM modules  
When the CPU enters a power state that causes the system power domain to go into WFI, DORMANT,

or OFF state, the local and global PRCM modules must be involved in the power transition.

#### 4.3.6.5 CPU0 and CPU1 Power Domains Description

The PD\_CPUx (where x = 1 or 2) contains the following reset domains:

- CPU0\_RST
- CPU0\_PWRON\_RST
- CPU1\_RST
- CPU1\_PWRON\_RST

The PD\_CPUx contains the following clock domains:

- CD\_CPU0
- CD\_CPU1

Table 4-8 lists the logic retention capability for each module of the PD\_CPUx.

**Table 4-8. PD\_CPUx Modules Power Attributes**

Module	Logic Retention	DFF Context Status	RFF Context Status
CPUx	No	RM_PDA_CPUi_CONTEXT[0] LOSTCONTEXT_DFF	None

The DFF-based logic is nonretention flip flop. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

#### 4.3.6.5.1 Power Domain Modes

This section describes the various power modes supported by the logic and memory areas of the power domain. It also identifies the software control and associated status bit fields. For a functional description of the power-management architecture of a generic power domain, see [Power Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

##### 4.3.6.5.1.1 Logic and Memory Area Power Modes

Table 4-9 lists the power modes supported by the logic area of the power domain.

**Table 4-9. PD\_CPUx Logic Area Power Modes**

OFF	RETENTION-OSWR	RETENTION-CSWR	ON-INACTIVE	ON-ACTIVE
Available	Available	Available	Available	Available

Table 4-10 lists the power modes supported by the memory area of the power domain. A memory area power mode is identified with respect to a power state of the power domain. The Logic ON, Logic RETENTION, and Logic OFF columns identify the power states of the power domain. The values in these columns identify the supported power state of the memory area (see the Memory Bank column) or the module memory inside the memory area (see the Module – Memory column).

**Table 4-10. PD\_CPUx Memory Area Power Modes**

Memory Bank	Module – Memory	Logic ON	Logic RETENTION	Logic OFF
CPU0_L1		ON	OFF, RETENTION	OFF
	CPU0-CPU0_L1	always_on	software_control	
CPU1_L1		ON	OFF, RETENTION	OFF
	CPU1-CPU1_L1	always_on	software_control	

#### 4.3.6.5.1.2 Logic and Memory Area Power Modes Control and Status

Table 4-11 lists the power mode controls for the power domain.

**Table 4-11. PD\_CPUx Power Mode Control Parameters**

Parameter Name	Memory Bank	Control Bit Field	Access Type
Memory Area – State Control (Logic in RETENTION state)	CPUx_L1	PM_PDA_CPUi_PWRSTCTRL[8] L1_BANK_RETSTATE	Read only
Memory Area – State Control (Logic in ON state)	CPUx_L1	PM_PDA_CPUi_PWRSTCTRL[17:16] L1_BANK_ONSTATE	Read only
Logic Area – Retention State Control		PM_PDA_CPUi_PWRSTCTRL[2] LOGICRETSTATE	Read/write
Power Domain – State Transition Control		PM_PDA_CPUi_PWRSTCTRL[1:0] POWERSTATE	Read/write

Table 4-12 lists the status of the power modes for the power domain.

**Table 4-12. PD\_CPUx Power Mode Status Parameters**

Parameter Name	Memory Bank	Status Bit Field
Memory Area – State Status	CPUx_L1	PM_PDA_CPUi_PWRSTST[5:4] L1_BANK_STATEST
Power Domain – State Transition Status		PM_PDA_CPUi_PWRSTST[20] INTRANSITION
Logic Area – State Status		PM_PDA_CPUi_PWRSTST[2] LOGICSTATEST
Power Domain – State Status		PM_PDA_CPUi_PWRSTST[1:0] POWERSTATEST

Table 4-13 lists the supported clock-management modes and the associated software control bit fields for each module of the power domain.

**Table 4-13. Module Clock Management Modes and Control**

Module	Clock Management Protocol	Status Bit Field	Role
CPUx	Master/Slave	CM_PDA_CPUi_CLKCTRL[0] STBYST	Standby status

Table 4-14 lists the supported clock-management modes and associated software control bit fields for each module of the power domain.

**Table 4-14. Module Slave Clock Management Modes and Control**

Module	Disabled	Auto	Enabled	Control Bit Field	Access Type
CPUx	n/a	Available	n/a	CM_PDA_CPUi_CLKCTRL[1:0] MODULEMODE	Read/write

## 4.4 Dual Cortex-A9 MPU Subsystem Register Manual

### 4.4.1 Cortex-A9 MPU Subsystem Instance Summary

**Table 4-15. Cortex-A9 MPU Instance Summary**

Module Name	Base Address	Size
SCU	0x4824 0000	128 bytes
GIC_Proc_Interface <sup>(1)</sup>	0x4824 0100	256 bytes
Timer	0x4824 0600	256 bytes
GIC_Intr_Distributor <sup>(2)</sup>	0x4824 1000	4KB
PL310	0x4824 2000	4KB
CORTEXA9_SOCKET_PRCM	0x4824 3000	512 bytes
CORTEXA9_PRCM	0x4824 3200	512 bytes
CORTEXA9_CPU0	0x4824 3400	1KB
CORTEXA9_CPU1	0x4824 3800	1KB
CORTEXA9_WUGEN	0x4828 1000	4KB
CMU	0x4829 0000	64KB
Local interconnect	0x482A 0000	4KB
MA	0x482A F000	4KB

<sup>(1)</sup> Processor interfaces: Handles interrupt acknowledgment, interrupt masking, and interrupt completion acknowledgment

<sup>(2)</sup> Interrupt distributor: Handles interrupt detection, interrupt prioritization, and distribution of interrupts to the CPUs

### 4.4.2 SCU Registers

For information about the SCU registers and their description, see the *ARM® Cortex™-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

### 4.4.3 Interrupt Controller Registers

For information about the GIC registers and their description, see the *ARM® Cortex™-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

### 4.4.4 Timer Registers

For information about the timer registers and their description, see the *ARM® Cortex™-A9 MPCore Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

### 4.4.5 PL310 Registers

For information about the PL310 registers and their description, see the *ARM® PL310 Cache Controller Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

<b>Address Offset</b>	0x0000 000C	<b>Index</b>	I = 0 to 1
<b>Physical Address</b>	0x4824 340C 0x4824 380C	<b>Instance</b>	CORTEXA9_CPU0 CORTEXA9_CPU1
<b>Description</b>	This register controls the assertion/release of the CPU CORE reset. This is basically a software warm reset (that asserts CPUx_RST) per CPU. One CPU can set this bit to reset the other CPU. Actually the CPU can set this bit to reset itself as well (and it will be kept in reset until the other active CPU clears this bit).		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												RST			

Bits	Field Name	Description	Type	Reset
31:1	RESERVED	Reserved	R	0x0000 0000
0	RST	CPU warm local reset control 0x0: Reset is cleared 0x1: Reset is asserted	RW	0

<b>Physical Address</b>	0x4824 3418 0x4824 3818	<b>Instance</b>	CORTEXA9_CPU0 CORTEXA9_CPU1
<b>Description</b>	This register enables the CPU domain power state transition. It controls the hardware-supervised domain power state transition between ON-ACTIVE and ON-INACTIVE states. It also holds 1 status bit per clock input of the domain.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																												CLKTRCTRL			

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	Reserved	R	0x0000 0000
1:0	CLKTRCTRL	Controls the full domain transition of the CPU domain.  0x0: NO_SLEEP: Sleep transition cannot be initiated. Wake-up transition may however occur.  Read 0x1: Reserved  0x2: Start a software forced wake-up transition on the domain. The software forced wake-up transition allows the software to wakeup a powered-down CPU by a method other than an externally triggered interrupt.  0x3: HW_AUTO: Automatic transition is enabled. Sleep and wake-up transition are based upon hardware conditions. WFI triggers the sleep transition based on settings in <a href="#">CM_PDA_CPUi_CLKSTCTRL</a> and <a href="#">PM_PDA_CPUi_PWRSTCTRL</a> registers.	RW	0x0

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	CORTEXA9_WUGEN
<b>Physical Address</b>	0x4828 1000		
<b>Description</b>	Wake-up generator status register for CPU0		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																DOMAIN_RST	CORTEXA9_WARM_RST	CORTEXA9_COLD_RST	WDT_RST	RESERVED	EVENTO	STANDBYWFE	STANDBYWFI	RESERVED							

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x00000
15	DOMAIN_RST	MPU always-on power domain (PD_ALWON_MPU) reset status bit. It shows if the reset occurred previously. 0x0: no reset occur 0x1: reset occur	R	0
14	CORTEXA9_WARM_RST	This bit is set when the CORTEXA9_RSTN signal is asserted. 0x0: CORTEXA9_RSTN reset signal has not been asserted 0x1: CORTEXA9_RSTN reset request has been asserted	R	0

Bits	Field Name	Description	Type	Reset
13	CORTEXA9_COLD_RST	This bit is set when the CORTEXA9_PWRON_RSTN signal is asserted. 0x0: CORTEXA9_PWRON_RSTN reset signal has not been asserted 0x1: CORTEXA9_PWRON_RSTN reset request has been asserted	R	0
12	WDT_RST	This bit is set when the WD timer Reset Request signal from the SCU is asserted. 0x0: WDT reset request has not been asserted 0x1: WDT reset request has been asserted	R	0
11	RESERVED	Reserved	R	0
10	EVENTO	EVENTO status bit. The event output signal is active, when one SEV instruction is executed. This bit is set when a rising edge of EVENTO from CPU is detected. 0x0: Rising edge of EVENTO is not detected 0x1: Rising edge of EVENTO is detected	R	0
9	STANDBYWFE	This bit gives software the visibility to track whether WFE mode have been entered. 0x0: WFE mode has not been entered 0x1: WFE mode has been entered	R	0
8	STANDBYWFI	This bit gives software the visibility to track whether WFI mode have been entered. 0x0: WFI mode has not been entered 0x1: WFI mode has been entered	R	0
7:0	RESERVED	Reserved	R	0

<b>Address Offset</b>	0x0000 0400	<b>Instance</b>	CORTEXA9_WUGEN
<b>Physical Address</b>	0x4828 1400		
<b>Description</b>	Wake-up generator status register for CPU1		
<b>Type</b>	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																DOMAIN_RST	CORTEXA9_WARM_RST	CORTEXA9_COLD_RST	WDT_RST	RESERVED	EVENTO	STANDBYWFE	STANDBYWF1	RESERVED								

Bits	Field Name	Description	Type	Reset
31:16	RESERVED		R	0x00000
15	DOMAIN_RST	MPU always-on power domain (PD_ALWON_MPU) reset status bit. It shows if the reset occurred previously. 0x0: no reset occur 0x1: reset occur	R	0
14	CORTEXA9_WARM_RST	This bit is set when the CORTEXA9_RSTN signal is asserted. 0x0: CORTEXA9_RSTN reset signal has not been asserted 0x1: CORTEXA9_RSTN reset request has been asserted	R	0
13	CORTEXA9_COLD_RST	This bit is set when the CORTEXA9_PWRON_RSTN signal is asserted. 0x0: CORTEXA9_PWRON_RSTN reset signal has not been asserted 0x1: CORTEXA9_PWRON_RSTN reset request has been asserted	R	0

Bits	Field Name	Description	Type	Reset
12	WDT_RST	This bit is set when the WD timer Reset Request signal from the SCU is asserted. 0x0: WDT reset request has not been asserted 0x1: WDT reset request has been asserted	R	0
11	RESERVED	Reserved	R	0
10	EVENTO	EVENTO status bit. The event output signal is active, when one SEV instruction is executed. This bit is set when a rising edge of EVENTO from CPU is detected. 0x0: Rising edge of EVENTO is not detected 0x1: Rising edge of EVENTO is detected	R	0
9	STANDBYWFE	This bit gives software the visibility to track whether WFE mode have been entered. 0x0: WFE mode has not been entered 0x1: WFE mode has been entered	R	0
8	STANDBYWFI	This bit gives software the visibility to track whether WFI mode have been entered. 0x0: WFI mode has not been entered 0x1: WFI mode has been entered	R	0
7:0	RESERVED	Reserved	R	0

<b>Address Offset</b>	0x804	<b>Instance</b>	CORTEXA9_WUGEN
<b>Physical Address</b>	0x4828 1804		
<b>Description</b>	This register is used by the ROM code and OS during SMP boot. It is intended to store the execution start address of CPU1. When needed, the SMP OS (executing on CPU0) stores the execution start address of CPU1 in <a href="#">AUX_CORE_BOOT_1</a> , and then wakes up CPU1 by executing a SEV command. When CPU1 received an event (caused by the SEV command), it executes the event handler in the ROM Code, which eventually branches to the address stored in <a href="#">AUX_CORE_BOOT_1</a> .

### 4.4.10.2 CMU Register Description

**Table 4-63. CMUCONFIGREG**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	CMU
<b>Physical Address</b>	0x4829 0000		
<b>Description</b>	CMU Configuration Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
THREADS				QENTRIES												RESERVED			DISABLEPIPELINING	DISABLEPARALLEL	INTEN	RESERVED			ENNSWR	LINESTEP					

Bits	Field Name	Description	Type	Reset
31:28	THREADS	Number of parallel CMO threads that can be simultaneously processed.	R	0x1
27:16	QENTRIES	Number of Queue Entries Configured	R	0x040
15:11	RESERVED	Reserved.	R	0x00
10	DISABLEPIPELINING	Disable pipelining of requests.	RW	1
9	DISABLEPARALLEL	Force sequential operation by disabling any parallelism between RangeSets.	RW	1
8	INTEN	Enable Interrupt on Set Completion. 0b0 = Don't interrupt. 0b1 = Interrupt on Completion.	RW	0
7:4	RESERVED	Reserved	R	0x0
3	ENNSWR	This enables Non-Safe programs to write this register. Out of reset - this bit is 0 which will prevent Non-Safe programs from writing it. Reading is always allowed. This bit can be set to 0x1 only through a Special Safe Monitor API. For more information about the API, see the Initialization chapter. The ROM Code will set this bit to 1 at boot time. The API can be used at runtime by the NS SW to enable/disable when necessary.	RW	0
2:0	LINESTEP	Size of smallest cache line size, log2 - 2. 0x0: Line Step = 4 bytes. 0x1: Line Step = 8 bytes. 0x2: Line Step = 16 bytes. 0x3: Line Step = 32 bytes. 0x4: Line Step = 64 bytes. 0x5: Line Step = 128 bytes. 0x6: Line Step = 256 bytes. 0x7: Line Step = 512 bytes.	R	0x3

<sup>(1)</sup> I = 0 to 63

### 4.4.12.2 MA Register Description

For the description of the MA registers, see [Section 15.2.6, DMM Register Manual](#), in [Section 15.2, Dynamic Memory Manager](#), where MA\_LISA\_LOCK corresponds to the DMM\_LISA\_LOCK register description, and MA\_LISA\_MAP\_i corresponds to the DMM\_LISA\_MAP\_i register description.

## DSP Subsystem

---

---

---

This chapter describes the digital signal processor (DSP) subsystem of the device.

Topic	Page
5.1 DSP Subsystem Overview .....	1155
5.2 DSP Subsystem Integration .....	1157
5.3 DSP Subsystem Functional Description .....	1160
5.4 DSP Subsystem Programming Guide .....	1199
5.5 DSP Subsystem Register Manual .....	1222

## 5.1 DSP Subsystem Overview

The device includes the digital signal processor (DSP) subsystem, based on a derivative of the TMS320DMC64x+™ very long instruction word (VLIW) DSP core.

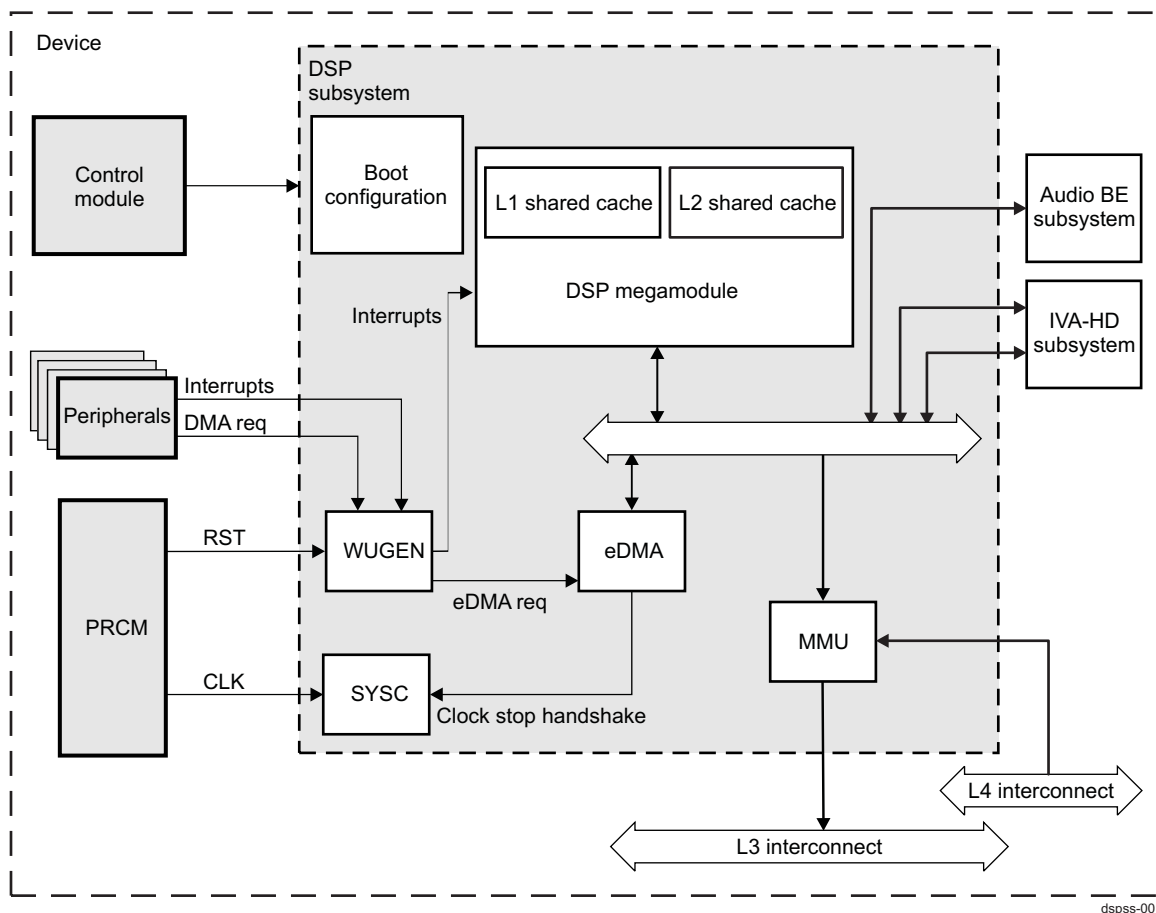

The internal architecture is an assembly of the following components:

- High-performance TI DSP (TMS320DMC64x™) derivative integrated in a megamodule, including local level 1 (L1) and level 2 (L2) cache and memory controllers for audio processing and general-purpose imaging and video processing
- L1 and L2 shared cache
- Subsystem counter timer module (SCTM)
- Dedicated enhanced data memory access (eDMA) engine to download/upload data from/to memories and peripherals external to the subchip
- Dedicated memory management unit (MMU) for accessing level 3 (L3) interconnect address space
- Local interconnect network
- Dedicated SYSC and wake-up generator (WUGEN) modules responsible for power management, clock generation, and connection to the power, reset, and clock management (PRCM) module

For information about C64x™ to C64x+™ core migration, see the documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).

Figure 5-1 is the DSP subsystem top-level architecture.

Figure 5-1. DSP Subsystem Highlight

### 5.1.1 DSP Subsystem Key Features

The main features of the DSP subsystem are:

- 32-bit fixed-point media processor
- VLIW architecture based on programmable enhanced version of the C64x DSP core
- Coprocessor connection through the coprocessor hardware Interface
- Four instructions per cycle, four execution units:
  - Optimized instruction set for video and image processing
  - Four 8 x 8 or 16 x 16 multiply accumulate (MAC) per cycle
  - Four slave synchronous die (SAD) per cycle
  - Eight interpolations  $(a + b + 1) \gg 1$  per cycle
  - Two (32-bit x 32-bit > 64-bit) multiply operations per cycle
- Low-power processor and megamodule:
  - Dynamically mixed 32-bit and 16-bit instruction sets
  - Separate power domain
  - Supported multiple power-down states
- 2-level memory subsystem hierarchy:
  - L1 (program and data):
    - 32-KB 4-way set associative cache-32-byte cache line
  - L2 (program and data):
    - 128-KB 8-way set associative cache-32-byte cache line
- Private direct memory access (DMA) controller:
  - 128 logical channels
  - 1-dimensional/2-dimensional (1D/2D) addressing
  - Chaining capability
  - Fully pipelined, two 64-bit read ports, two 64-bit write ports
  - Single-access 32- or 64-byte incrementing bursts
- L1 interrupt controller (INTC)
- Local DSP digital phase-locked loop (DPLL) supplying DSP subsystem clocking
- 32-entry MMU for seamless integration in high-level operating system (OS) environment
- DSP subsystem interfaces:
  - 64-bit L3 port shared for external memory accesses:
    - Multithreaded link shared by the DSP core and DMAs
    - Interface with the L3 interconnect that can be synchronous or asynchronous for clock decoupling between DSP and L3
    - Incrementing burst support
    - Critical line first, to reduce line-fetch latency to the processor
  - Host port interface (HPI) for MMU programming and access to DSP internal memories. Can be synchronous or asynchronous.
  - System interfaces: Clocking, power management
- C-friendly environment (state-of-the-art C-compiler for VLIW architecture)
- TI low-overhead DSP-BIOS™ OS
- Backward compatibility (not binary compatible) with existing C64x video coders/decoders (codecs) and high level of programmability and flexibility

Known restrictions on the C64x+ DSP core:

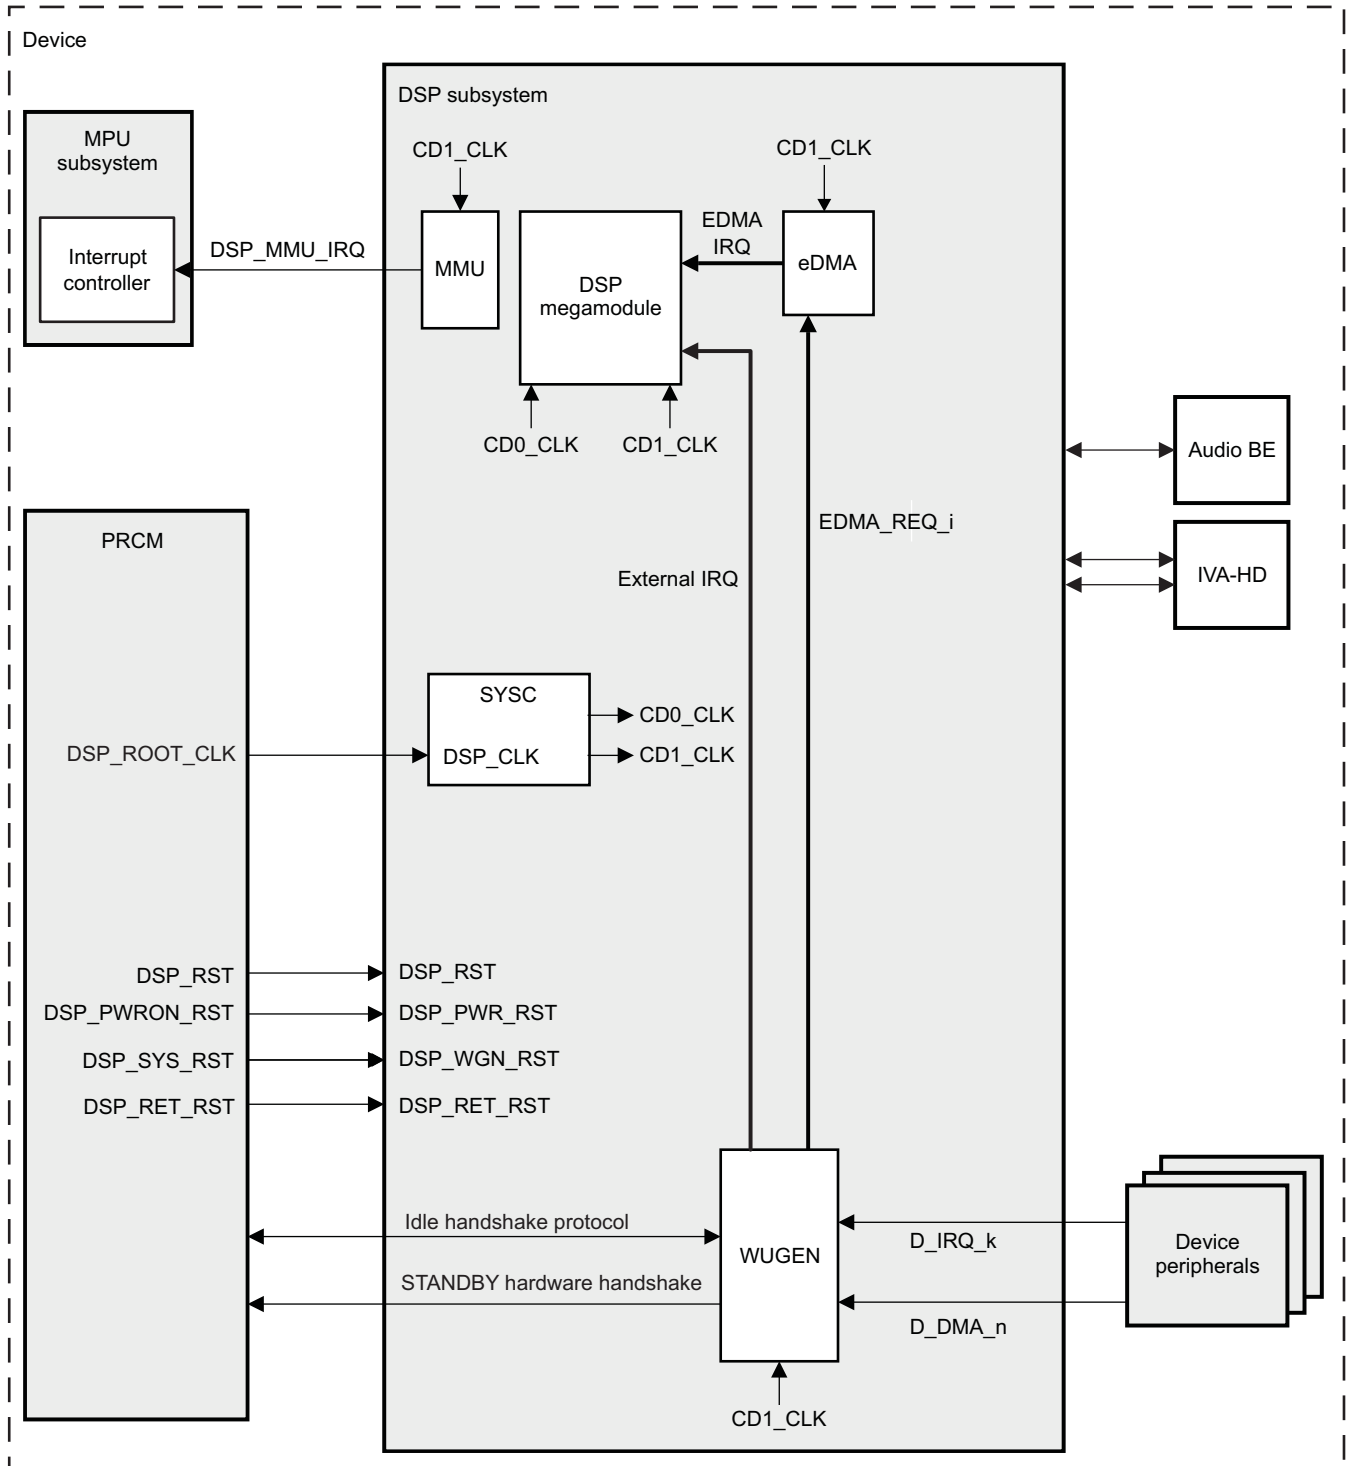

- 4-issue VLIW central processing unit (CPU) instead of 8-issue
- SPLOOP not supported
- L1 and L2 flat static random access memory (SRAM) not supported
- No EFI port

## 5.2 DSP Subsystem Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 5-2 shows the integration of the DSP subsystem.

Figure 5-2. DSP Subsystem Integration

dspss-002

**NOTE:** For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 5-1](#) through [Table 5-3](#) summarize the integration of the module in the device.

**Table 5-1. Integration Attributes**

Module Instance	Attributes	
	Power Domain	Interconnect
DSP	PD_DSP	L3

**Table 5-2. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DSP	DSP_CLK	DSP_ROOT_CLK	PRCM module	For information about PRCM clock gating and management, see <a href="#">, PD_DSP Description</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
DSP	DSP_PWR_RST	DSP_PWRON_RST	PRCM module	For information about PRCM reset sources and distribution, see <a href="#">, PD_DSP Description</a> , in <a href="#">Chapter 3, Power, Reset, and Clock Management</a> .
	DSP_RET_RST	DSP_RET_RST	PRCM module	
	DSP_WGN_RST	DSP_SYS_RST	PRCM module	
	DSP_RST	DSP_RST	PRCM module	

Hardware requests include interrupt requests and DMA requests. The DSP INTC receives interrupts from the DSP subsystem (internal) and from other modules (D\_IRQ\_k interrupt signals). For more information about interrupt requests, see [Table 5-6](#).

[Table 5-3](#) lists the DMA requests.

**Table 5-3. Hardware Requests – DMA Requests**

Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
DSP	MCBSP4_DMA_TX	D_DMA_0	dDMA	MCBSP4 transmit request
	MCBSP4_DMA_RX	D_DMA_1	dDMA	MCBSP4 receive request
	MCBSP1_DMA_TX	D_DMA_2	dDMA	MCBSP1 transmit request
	MCBSP1_DMA_RX	D_DMA_3	dDMA	MCBSP1 receive request
	MCBSP2_DMA_TX	D_DMA_4	dDMA	MCBSP2 transmit request
	MCBSP2_DMA_RX	D_DMA_5	dDMA	MCBSP2 receive request
	MCBSP3_DMA_TX	D_DMA_6	dDMA	MCBSP3 transmit request
	MCBSP3_DMA_RX	D_DMA_7	dDMA	MCBSP3 receive request
	Reserved	D_DMA_8-9	dDMA	Reserved
	UART3_DMA_TX	D_DMA_10	dDMA	UART3 transmit request
	UART3_DMA_RX	D_DMA_11	dDMA	UART3 receive request
	SLIMBUS1_DMA_TX0	D_DMA_12	dDMA	SLIMBUS1 transmit request channel 0

**Table 5-3. Hardware Requests – DMA Requests (continued)**

Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
	SLIMBUS1_DMA_TX1	D_DMA_13	dDMA	SLIMBUS1 transmit request channel 1
	SLIMBUS1_DMA_TX2	D_DMA_14	dDMA	SLIMBUS1 transmit request channel 2
	SLIMBUS1_DMA_TX3	D_DMA_15	dDMA	SLIMBUS1 transmit request channel 3
	SLIMBUS1_DMA_RX0	D_DMA_16	dDMA	SLIMBUS1 receive request channel 0

	MCPDM_DMA_DOWN	D_DMA_43	dDMA	McPDM downlink request
	DMIC_DMA_REQ	D_DMA_44	dDMA	DMIC DMA request
	Reserved	D_DMA_45-63	dDMA	Reserved

**NOTE:**

- For a description of the interrupt source, see [Section 5.3.7, Interrupt Requests](#).
- For a description of the DMA source, see [Section 5.3.8, DMA Requests](#).

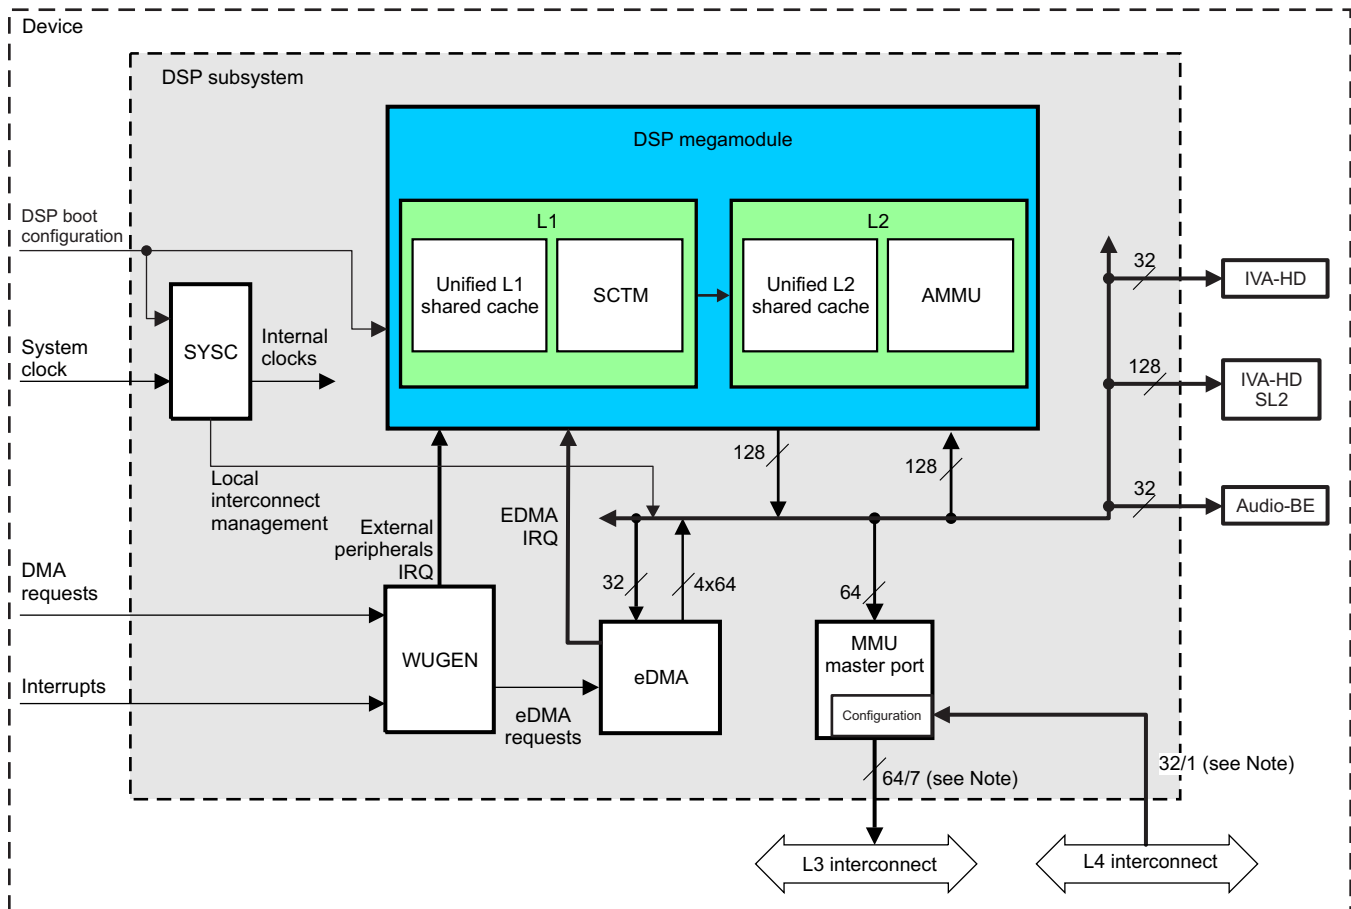

## 5.3 DSP Subsystem Functional Description

### 5.3.1 Block Diagram

The DSP subsystem is composed of a DSP megamodule coupled with several submodules that enable its integration in the device architecture. The DSP subsystem provides one slave port connected to the L4 interconnect (used to configure DSP MMU from the device Dual Cortex-A9 MPU) and one master port, which is connected to the L3 interconnect. It also provides three master ports for direct access to the IVA-HD subsystem (the IVA-HD and IVA-HD SL2 ports) and to the ABE port subsystem.

Figure 5-3 is a block diagram of the DSP subsystem.

**Figure 5-3. DSP Subsystem Block Diagram**

dspss-007

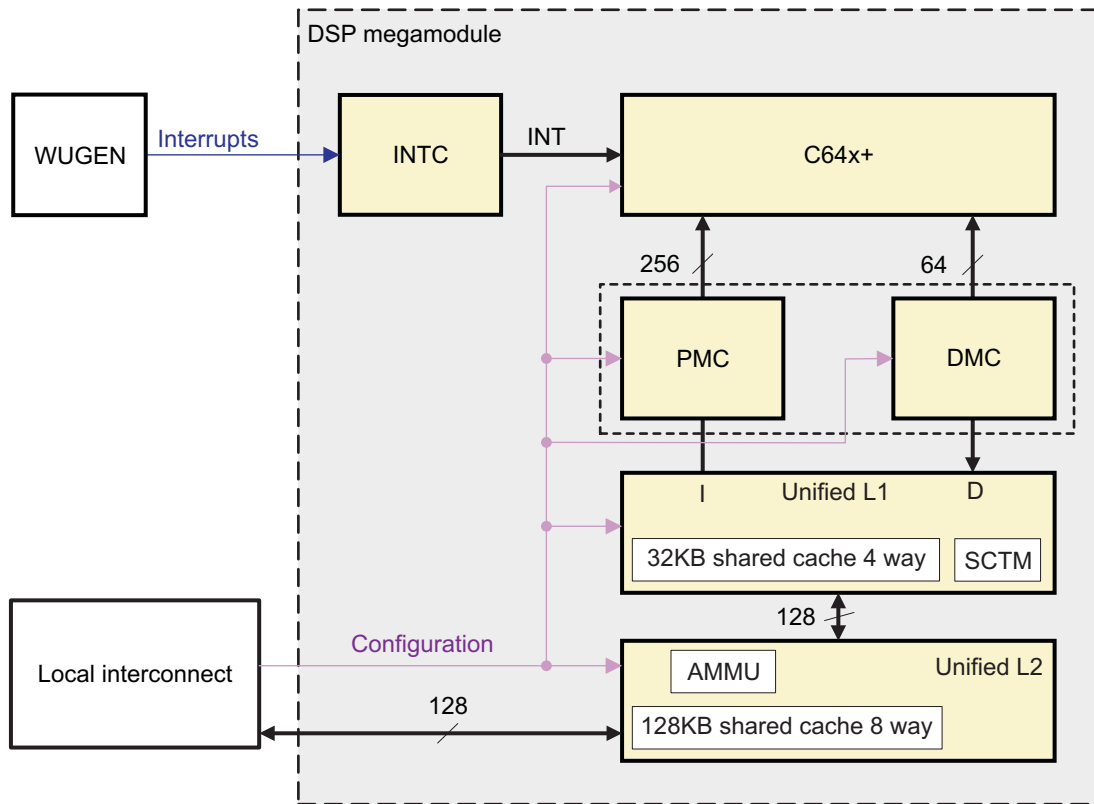

NOTE: The first number indicates bus width in bits, and the next indicates the number of L3 connected targets or initiators for DSPSS master and slave ports. For more information, see [Section 13.2, L3 Interconnect](#) in [Chapter 13, Interconnect](#).

### 5.3.2 DSP Megamodule

The C64x+ DSP megamodule is a class of derivative sections of the generalized embedded megamodule. The DSP megamodule is hardware-configurable and comprises a version of the C64x+, an L1 program memory controller (PMC), an L1 data memory controller (DMC), and L1/L2 unified caches.

Figure 5-4 is a block diagram of the DSP megamodule.

Figure 5-4. DSP Megamodule Block Diagram

dsps-008

### 5.3.2.1 DSP Overview

The C64x+ is an extension of the first C64x DSP section.

The DSP core features:

- 32-bit fixed-point media processor
- VLIW architecture
- Four instructions per cycle, four execution units
  - Optimized instruction set for video and image processing
  - Four 8 x 8 or 16 x 16 MACs per cycle
  - Four SADs per cycle
  - Eight interpolations (a + b + 1) >> 1 per cycle
  - Two (32-bit x 32-bit -> 64-bit) multiply operations per cycle

In addition to the existing C64x features, the C64x+ includes the following:

- Compact instructions
- Extended function support
- Exception handling
- Privilege mode support
- HLOS time-stamp counter register

Known restrictions on the C64x+ DSP core are:

- 4-issue VLIW CPU instead of 8-issue
- SPLOOP not supported

- L1 and L2 flat SRAM not supported
- No EFI port

For information about the C64x+ DSP, see the C64x+ reference manual listed in [Section 5.3.2.7](#), *Other DSP Reference Documents*.

### 5.3.2.2 PMC Overview

The PMC is the DSP megamodule component that delivers program fetch packets when they are requested by the DSP core.

The PMC supports the following features:

- One 256-bit fetch packet per cycle (sustainable)
- DMA transfer from/to L1/L2 caches
- Fair priority-based arbitration between DSP, DMA, and cache controller for access to the SRAM
- Block and global program-initiated cache coherence support (invalidate)
- Freeze mode

For more information, see [Section 5.4.5](#), *Memory Management*.

### 5.3.2.3 DMC Overview

The DMC is the DSP megamodule component that reads or writes data from/to local memories, as requested by the DSP.

The DMC supports the following features:

- One 64-bit memory access per cycle (sustainable)
- A memory access pair can be any combination of read and write, with no incurred penalty.
- DMA transfer from/to L1/L2 caches
- Fair priority-based arbitration between the DSP, DMA, and cache controller for access to the SRAM
- Hardware coherence maintenance with L2 (snooping)
- Block and global program-initiated cache coherence support (write-back, invalidate, and write-back-invalidate)
- Freeze and bypass mode

### 5.3.2.4 Unified L1/L2 Cache Overview

The following features are supported by the shared cache design:

- 32-KB L1 unified cache implemented with high-performance bit cell to run at full speed
- 128-KB L2 unified cache implemented with high-density bit cell to optimize area at half speed
- L1 cache is 32B line size, 4-way set-associative and organized as 16-bank.
- L2 cache is 32B line size and 8-way set associative.
- L1 cache supports snooping.
- L2 cache slave port to support snooping from eDMA accesses
- Fully pipelined/supports critical-word-first
- Write-combining
- Fill and eviction buffers, and hit in fill buffer
- Dynamic sizing, I/D allocation
- Prefetch 4 lines/preload N lines
- Background preload/clean

### 5.3.2.5 Attribute MMU Overview

The attribute MMU (AMMU) for the shared cache provides the multi-access cache with a region-based address translation, read/write control, access type control, endianness, and multilevel cache maintenance.

The MMU is directly connected to the shared cache, and there is a dedicated interface for pipeline write policy management. L1 policies are queried at the allocation control of the cache, and L2 policies are propagated to the master interface.

For flexibility, the MMU can be dedicated to an L1 or an L2 cache configuration, with or without address translation, or as an L1/L2 cache combination.

The AMMU supports different page sizes: large, medium, and small. The number of large pages, number of medium pages, etc., is defined at design time. The maximum number of large pages is eight. This address space includes addresses for all eight regions. However, if the DSP subsystem defines only five large pages, only the first five addresses are valid.

The page sizes for the 17 entries are:

- Large pages (eight): The page size supported is 512MB.
- Medium pages (seven): The page sizes supported are 128KB and 1MB.
- Small pages (two): The page sizes supported are 4KB and 32KB.

The size of the page is configured by setting:

- [SCACHE\\_MMU\\_LARGE\\_POLICY\\_i\[1\] SIZE](#)
- [SCACHE\\_MMU\\_MED\\_POLICY\\_j\[1\] SIZE](#)
- [SCACHE\\_MMU\\_SMALL\\_POLICY\\_k\[1\] SIZE](#)

The logical source address is configured in:

- [SCACHE\\_MMU\\_LARGE\\_ADDR\\_i\[31:25\] ADDRESS](#)
- [SCACHE\\_MMU\\_MED\\_ADDR\\_j\[31:17\] ADDRESS](#)
- [SCACHE\\_MMU\\_SMALL\\_ADDR\\_k\[31:12\] ADDRESS](#)

The logical source translated address is configured in:

- [SCACHE\\_MMU\\_LARGE\\_XLTE\\_i\[31:25\] ADDRESS](#)
- [SCACHE\\_MMU\\_MED\\_XLTE\\_j\[31:17\] ADDRESS](#)
- [SCACHE\\_MMU\\_SMALL\\_XLTE\\_k\[31:12\] ADDRESS](#)

When the SIZE bit is set to 0, all the bits in the ADDRESS bit field of the corresponding logical source address and logical source translated address can be used.

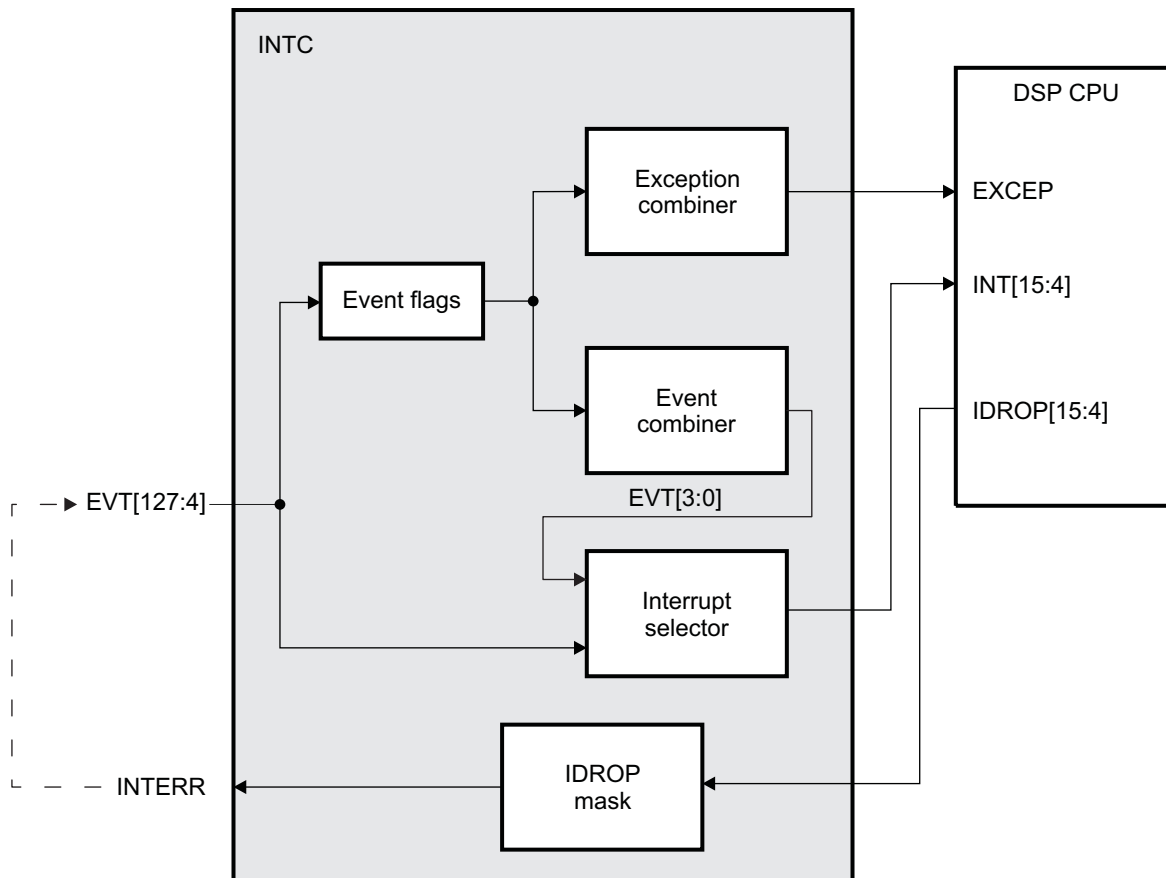

When the SIZE bit is set to 1, the ADDRESS bit field of the corresponding logical source address and logical source translated address must be programmed only with addresses that can address the size of a second possible page.

### 5.3.2.6 INTC

The DSP megamodule INTC detects, potentially combines, and routes up to 128 system events (internal and external) to the DSP CPU interrupt lines. [Table 5-6](#) lists the global interrupt mappings of the DSP subsystem (internal and external interrupts).

The DSP CPU has 12 maskable interrupts and one exception input. The INTC includes an interrupt selector, exception combiner, and event combiner. The interrupt selector allows the routing of any of the 128 system events (or a combination of them) to the 12 maskable interrupts of the DSP CPU, and software determines the priorities of those system events. To handle potential conflicts, the 12 CPU interrupts have fixed priorities. The exception combiner allows the combination of any of the 128 system events to the single exception input of the DSP CPU (see [Figure 5-5](#)).

Figure 5-5. DSP Megamodule INTC Block Diagram

dspss-009

**NOTE:** Not all 128 event inputs of the INTC are connected to an internal or external event line. [Table 5-6](#) lists the global interrupt mapping of the DSP INTC. Some interrupts at the DSP boundary are reserved for future use or are not used by the DSP subsystem. For information about the DSP core INTC, see the C64x+ DSP documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).

### 5.3.2.6.1 Event Type

The INTC provides three types of interrupt sources to the DSP CPU:

- Single event
  - A single system event can be directly routed to a CPU interrupt input.
  - A dropped system event is supported through the CPU dropped interrupt reporting mechanism (if the CPU misses the interrupt input, the system event is missed).
- Combined event
  - Up to four event combiners
  - Each combiner allows up to 32 system events to be logically ORed into a single event that can be routed to the DSP CPU.
- Exception event: This event is considered a single event, but it is directly connected to the exception input of the DSP CPU.

### 5.3.2.6.2 Event Behavior

- Single event source: The interrupt selector routes 1 of 124 events to a DSP CPU interrupt, as

programmed in the interrupt selector registers (SYS\_INTC\_INTMUX<sub>j</sub>, where  $j = 1$  to 3). Logic in the CPU and INTC combine to detect instances in which an interrupt request is asserted before an earlier interrupt request is serviced. The INTC records the interrupt number of the first interrupt and keeps this information until directed to release the interrupt, either through reset or by application software. This record can be used as an additional system event to notify the application of an interrupt failure. Interrupts that qualify for dropped detection are defined through an IDROP mask that sets the [SYS\\_INTC\\_INTDMASK](#) register. The masked IDROP event output (EVT96; see [Table 5-6](#)) is available as a system event that can be selected as a DSP CPU interrupt or an exception event.

- **Combined source:** The event combiners create a combined event from the logical OR of 32 system-event flags qualified by a mask provided through programmable registers (SYS\_INTC\_EVTMASK<sub>i</sub>, where  $i = 0$  to 3). The combination of the event flags creates an event that is asserted when any of the event flags included in its generation is active. Software must clear the event flags (SYS\_INTC\_EVTCLR<sub>i</sub>, where  $i = 0$  to 3) to deassert a combined event.

---

**NOTE:** The use of event flags makes it impossible for the CPU to detect the dropping of independent system events; therefore, dropped interrupt capability is not directly supported for combined events.

---

The interrupt event combiners create four shared interrupt sources:

- EVT0: Logical OR of SYS\_INTC\_EVTFLAG<sub>i</sub>[31:4] (where  $i = 0$ ) masked by SYS\_INTC\_EVTMASK<sub>i</sub>[31:4] ( $i = 0$ )
- EVT1: Logical OR of SYS\_INTC\_EVTFLAG<sub>i</sub>[63:32] (where  $i = 1$ ) masked by SYS\_INTC\_EVTMASK<sub>i</sub>[63:32] ( $i = 1$ )
- EVT2: Logical OR of SYS\_INTC\_EVTFLAG<sub>i</sub>[95:64] (where  $i = 2$ ) masked by SYS\_INTC\_EVTMASK<sub>i</sub>[95:64] ( $i = 2$ )
- EVT3: Logical OR of SYS\_INTC\_EVTFLAG<sub>i</sub>[127:96] (where  $i = 3$ ) masked by SYS\_INTC\_EVTMASK<sub>i</sub>[127:96] (where  $i = 3$ )

SYS\_INTC\_EVTFLAG<sub>i</sub> are the event flag registers and SYS\_INTC\_EVTMASK<sub>i</sub> are the event mask registers. These combined events are presented to the interrupt selection logic.

- **Exception event source:** As with the event combiner, the exception combiner allows multiple system events to be grouped as a single event input to the CPU, and the combiner provides mask registers to remove undesirable events. Because only one exception is input to the CPU, all mask registers work together to combine up to 128 events as a single EXCEP output. This lets the CPU service all available system exceptions.

The shared exception source is created as follows:

EXCEP: Logical OR of EF[127:4] masked by XM[127:4]

Where  $EF[i \times 32 + j] = EVTFLAG_i[j]$  and  $XM[i \times 32 + j] = EXPMASK_i[j]$  ( $i = 0, 1, 2, 3$  and  $j = 0$  to 31).

The logic is similar to that of the event combiners, except that only one combined event is routed to EXCEP.

### 5.3.2.6.3 Event Detection

The INTC contains a set of status and control registers to manage the status of system events received by the controller. These include set, flag, and clear registers that cover all 128 system events. Enabling of the events is managed in the CPU for direct mapped interrupts, in the event combiner for combined events, and in the exception combiner for system exceptions. Events to the INTC can be enabled or disabled only at the event source.

The event flag registers (SYS\_INTC\_EVTFLAG<sub>i</sub>, where  $i = 0$  to 3) capture every system event received, regardless of its destination: event combiner, exception combiner, or interrupt selector. Events that are not masked by the event combiner or the exception combiner are captured in the SYS\_INTC\_EVTFLAG<sub>i</sub> register (where  $i = 0$  to 3) corresponding to the event and are used to determine when the combined event is generated. Events that are masked by the event combiner or the exception combiner are captured in the SYS\_INTC\_EVTFLAG<sub>i</sub> register but do not affect when the DSP CPU interrupt is generated.

The event flags in the `SYS_INTC_EVTFLAGi` registers retain the value of 1 for any event received. These registers are read-only and must be cleared through the write-only `SYS_INTC_EVTCLRi` registers. The `SYS_INTC_EVTSETi` registers can be used to manually set bits in the `SYS_INTC_EVTFLAGi` registers, including those that are masked.

---

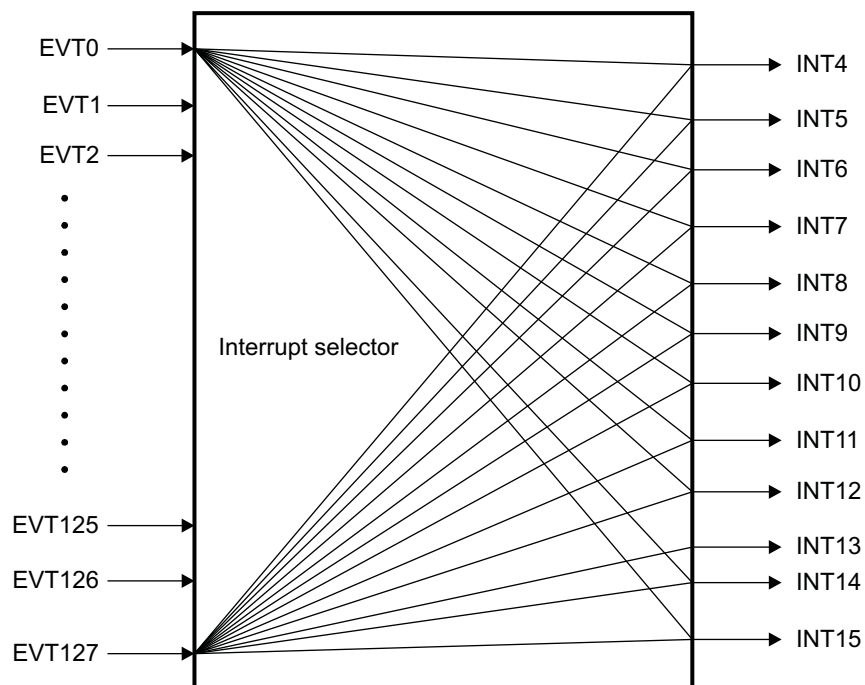

**NOTE:** Because external events are maintained by the peripheral until they are explicitly cleared by software, drop event detection does not work for external events (interrupts from peripherals external to the DSP subsystem).

---

#### 5.3.2.6.4 Event Selection

The DSP CPU has 12 available maskable interrupts. The interrupt selector allows any of the 128 system events, either from the event inputs or from the event combiners, to be routed to any of the 12 CPU interrupt inputs (see [Figure 5-6](#)).

**Figure 5-6. Interrupt Selector Block Diagram**

dspss-010

Users can choose which of the 128 input events is mapped to each of the 12 CPU interrupts by writing the event number in the bit field corresponding to the CPU interrupt in the `SYS_INTC_INTMUXj` register. CPU priority is fixed. This event -> interrupt mapping allows software to define the priority of the event. For more information, see [Section 5.4](#), *DSP Subsystem Basic Programming Guide*.

#### 5.3.2.6.5 Event Combination

The event combiner allows multiple system events to be combined into a single event for routing to the interrupt selector. This allows the CPU to service all available system events, even though only 12 are available.

A set of event mask registers (`SYS_INTC_EVTMASKi`, where  $i = 0$  to 3) is used to program the event combiner. These registers allow up to 32 events to be combined into a single event output that is used as one DSP CPU interrupt. The event mask bits in the `SYS_INTC_EVTMASKi` registers act as enablers for the received system events combined on the event outputs. There are four event outputs to the interrupt selector (`EVT[3:0]`).

By default, every system event is unmasked and combined with its associated EVT<sub>x</sub>. To mask out an event source (for example, to disable an event from being combined), the corresponding mask bit (the SYS\_INTC\_EVTMASK<sub>i[y]</sub> EMy bit for EVT<sub>y</sub>) must be set to 1.

---

**NOTE:** Because the event masks for events 0 through 3 are combined events, and thus cannot contribute to the generation of a combined event, they are reserved.

---

For more information, see [Section 5.4.4, Interrupt Management](#).

#### 5.3.2.6.6 Interrupt Event Error

The INTC can generate a system event internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is received while the interrupt flag (IFR, internal DSP register) is already set in the CPU. This signals possible problems in the code, such as whether interrupts were disabled for an extended time or pipelined (noninterruptible) code sections were too long.

---

**NOTE:** The same strategy of register settings (events, event set, event clear, event mask) is used in the WUGEN (which is not an INTC), which enables defining wake-up events so they can wake up the DSP subsystem. For more information, see [Section 5.3.9, Wake-Up Generator](#).

---

For more information on interrupt management, see [Section 5.4.4, Interrupt Management](#). For information on associated programming, see [Section 5.4, DSP Subsystem Programming Guide](#).

#### 5.3.2.7 Other DSP Reference Documents

For more information about the DSP megamodule architecture, instruction set, and DSP core INTC, and for a complete description of the DSP memory-mapped registers, see the following documents ([www.ti.com](http://www.ti.com)):

- *TMS320C6000 DSP Peripherals Overview Reference Guide* (TI Literature number SPRU190) describes the peripherals available on the TMS320C6000 DSPs.
- *TMS320C64x Technical Overview* (TI Literature number SPRU395) introduces the TMS320C64x DSP and discusses the application areas enhanced by the TMS320C64x VelociT.
- *TMS320C64x+ DSP Megamodule Reference Guide* (TI Literature number SPRU871) describes the C64x+ megamodule peripherals.
- *TMS320C64x/C64x+ DSP CPU and Instruction Set Reference Guide* (TI Literature number SPRU732)
- *TMS320C6000 Programmer's Guide* (TI Literature number SPRU198) describes ways to optimize C and assembly code for the TMS320C6000 DSPs, and includes application program examples.

### 5.3.3 eDMA

The DSP subsystem has an eDMA to transfer instructions and data from/to external memory connected to the L3 interconnect to/from L1 and L2 local memories in the DSP megamodule. The eDMA can also perform transfers between external memories and between DSP megamodule internal memories, with some performance loss caused by resource sharing between the read and write ports. For transfers between DSP megamodule internal memories, use the eDMA with the locked feature.

The eDMA is based on two primary components:

- DMA third-party channel controller (TPCC)
- DMA third-party transfer controller (TPTC)

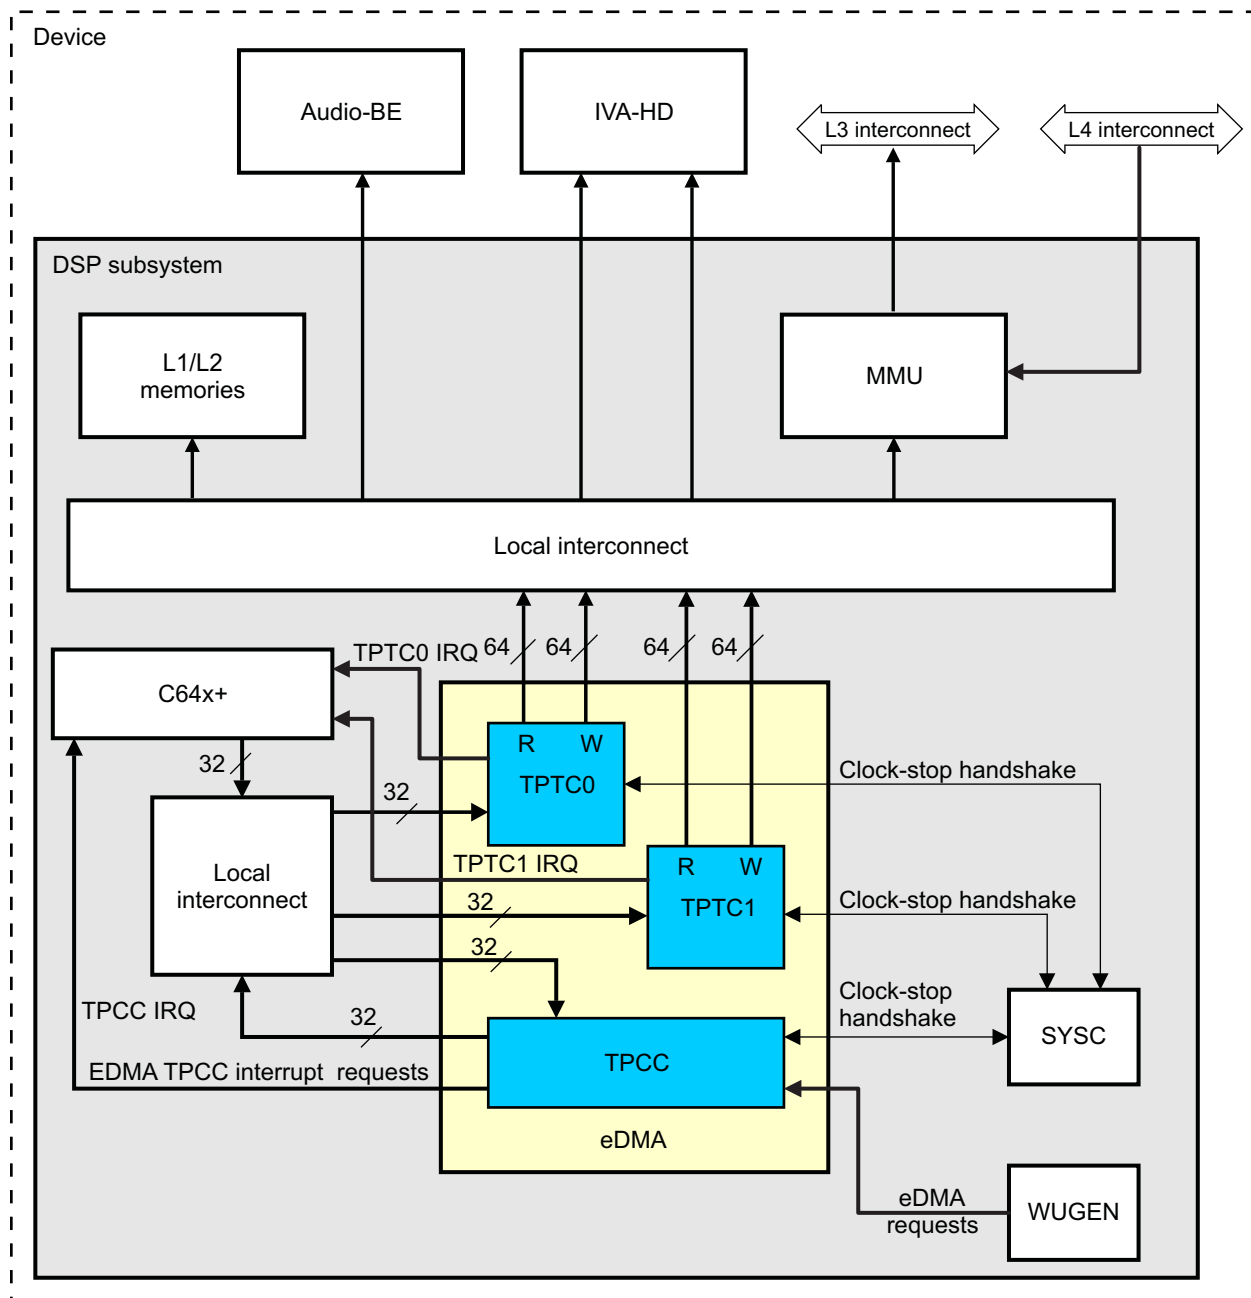

There are two instances of the TPTC in the DSP subsystem.

[Figure 5-7](#) shows how the eDMA is integrated in the DSP subsystem:

- Code running on the DSP can configure the eDMA; through the configuration port of the DSP megamodule and the local interconnect, the code can program DMA transfers and trigger them by software by writing to the TPCC configuration registers.
- Preprogrammed DMA transfers can be triggered by external events, referred to in this chapter as DMA requests.

- The TPCC schedules DMA transfers to the TPTC DMA engines (TPTC0 and TPTC1) through dedicated local interconnect 32-bit configuration ports.
- Each TPTC issues concurrent traffic on the local interconnect through dedicated read and write 64-bit ports.
- Interrupts generated by the eDMA are routed to the DSP INTC.
- Power-management handshakes are exchanged between eDMA components and the SYSC.

Figure 5-7. DSP eDMA Overview

dspss-011

### 5.3.3.1 Third-Party Channel Controller

The TPCC is the DMA transfer scheduler responsible for scheduling, arbitrating, and issuing user-programmed transfers to the two TPTCs.

### 5.3.3.1.1 TPCC Features

The TPCC features are:

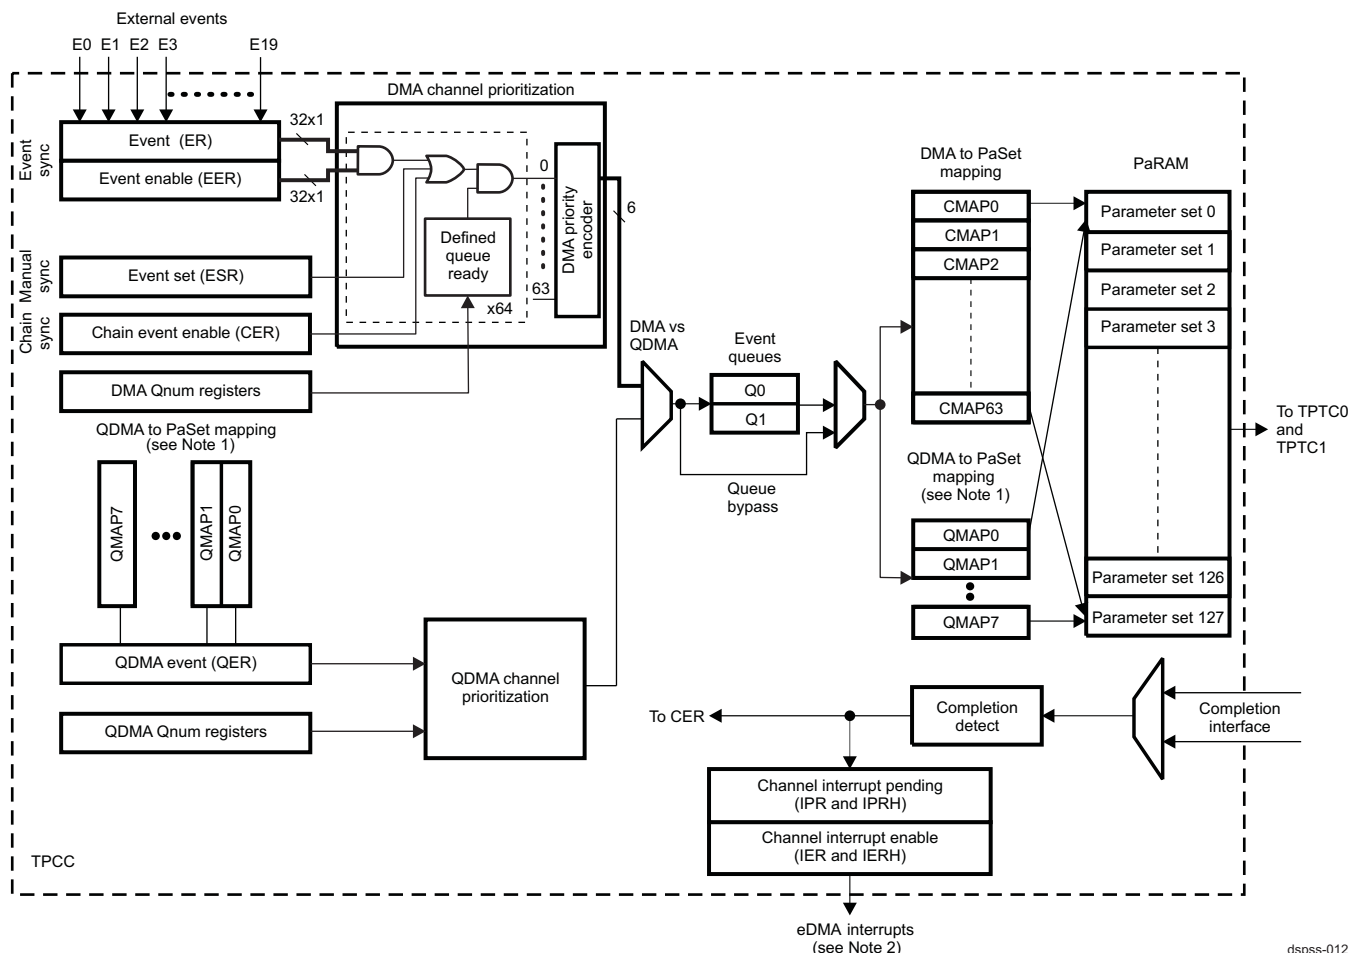

- Parameter RAM (PaRAM) entries, which hold up to 128 transfer contexts, with the following capabilities:
  - Ping-pong and circular buffering
  - Channel chaining
  - Auto-reloading

Each PaRAM entry can be used as a DMA entry (up to 64), QDMA entry (up to 8), or link entry (remaining):

- Up to 64 DMA logical channels:
  - 64 channels can be triggered explicitly by the DSP CPU (DMA entry).
  - 64 channels can be triggered by external events (see [Table 5-3](#)).
  - All channels can be triggered by completion of a previous transfer in a user-programmed chain of transfers (linked entry).
- 12 interrupt lines connected to the DSP CPU
- Boundaries for synchronization with the CPU are programmable.
- Two queues holding events waiting for submission to the TPTC
- Each transfer can be programmed to a priority level (three possible levels).

[Figure 5-8](#) is a block diagram of the TPCC.

Figure 5-8. TPCC Block Diagram

- (1) Although it is depicted twice in Figure 5-8, there is only one physical register set for the QDMA to PaRAM set mapping block.
- (2) For more information, see Table 5-6.

A channel is a specific event that can cause a transfer to be submitted to the TPTCs as a transfer request. The TPCC supports up to 64 DMA channels and up to 8 QDMA channels. These channels are identical, except for how they are triggered:

- DMA channels can be triggered by external events (such as McBSP TX Evt and McBSP RX Evt) by the software writing 1 to a given bit location or channel, by the event set register, or through chaining.
- QDMA channels are triggered automatically (auto-triggered) by the CPU. QDMAs allow a minimum number of linear writes to be issued to the TPCC to force a series of transfers to occur.

The TPCC arbitrates among pending DMA and QDMA events with a fixed 64:1 and 4:1 priority encoder for these events, respectively (a low channel number corresponds to a high priority). DMA events are always higher priority than QDMA events. The higher-priority event is placed in the event queue to await submission to the transfer controller, which occurs at the earliest opportunity. Each event queue is serviced in FIFO order, with a maximum of 16 queued events per event queue. If more than one TPTC is ready to be programmed with a transmission request (TR), the event queues are serviced with fixed priority: Q0 is higher than Q1. When an event is ready to be queued and the event queue and the TC channel are empty, the event bypasses the event queue and goes directly to the PaRAM processing logic for submission to the appropriate TC. If the TR bus/PaRAM processing is busy, the bypass path is not used. The bypass is not used to dequeue for a higher-priority event.

Events are extracted from the event queue when the TPTC is available for a new TR to be programmed into the TPTC (signaled with the empty signal, indicating an empty program register set). As an event is extracted from the event queue, the associated PaRAM entry is processed and submitted to the TPTC as a TR. The TPCC updates the appropriate counts and addresses in the PaRAM entry in anticipation of the next trigger event for that PaRAM entry. The PaRAM entry consists of eight words of DMA context, including source address, destination address, count, indexes, etc.

### 5.3.3.1.2 DMA Versus QDMA

The only difference between a QDMA and a DMA transfer is the means of generating and recognizing TR synchronization. From the user point of view, DMA and QDMA transfer types can be combined to perform various types of transfers.

DMA channel TR synchronization can be generated from one of three sources:

- Event-triggered: The event register ([TPCC\\_ER](#)) channel *n* bit is set as the result of an external event. An external event is latched in the event register. If the corresponding event is enabled through the event enable register ([TPCC\\_EER](#)), this is recognized as a TR synchronization.
- Manually triggered: The event set register channel *n* bit is set manually to the event set registers ([TPCC\\_ESR](#) and [TPCC\\_ESRH](#)) for channel *n* (the [TPCC\\_ESR\[n\]](#) En bit or [TPCC\\_ESRH\[n\]](#) En bit). Manually set events do not have to be enabled to be recognized as a TR synchronization.
- Chain-triggered: The chain event register channel *n* (the [TPCC\\_CER](#) and [TPCC\\_CERH](#) registers) bit is set when a chaining completion code is detected on the completion interface for channel *n*. Chain events do not have to be enabled. If a chain trigger is detected, this is always recognized as a TR synchronization.

QDMA TR synchronization occurs in one of two ways:

- Auto-triggered: The QDMA event register channel *n* (the [TPCC\\_QER](#) and [TPCC\\_QER\\_RN\\_k\[n\]](#) En) bit is set when a CPU write address matches the address defined by the QDMA mapping register for channel *n* ([TPCC\\_QCHMAPN\\_j](#)) and the QDMA channel is enabled (the [TPCC\\_QEER\[n\]](#) En bit field).
- Link-triggered: The [TPCC\\_QER\[n\]](#) En bit is set when a link update is performed on a PaRAM address that matches the [TPCC\\_QCHMAPN\\_j](#) setting, and the [TPCC\\_QEER\[n\]](#) En bit is set.

There is a subtle difference between each trigger type and the associated enablers. Event assertion always results in the [TPCC\\_ER\[n\]](#) En bit being set, regardless of the state of the enable ([TPCC\\_EER.En](#)). It is recognized as a TR synchronization only if enabled. Chain triggering always sets the [TPCC\\_CER\[n\]](#) En bit and is always treated as a TR synchronization. Manual triggering always sets the [TPCC\\_ESR\[n\]](#) En bit and is always treated as a TR synchronization. Auto-triggering (QDMA) sets only the event register [TPCC\\_QER\[n\]](#) En bit only if the corresponding event is enabled ([TPCC\\_QEER\[n\]](#) En); when the [TPCC\\_QER\[n\]](#) En bit is set, it is always treated as a TR synchronization.

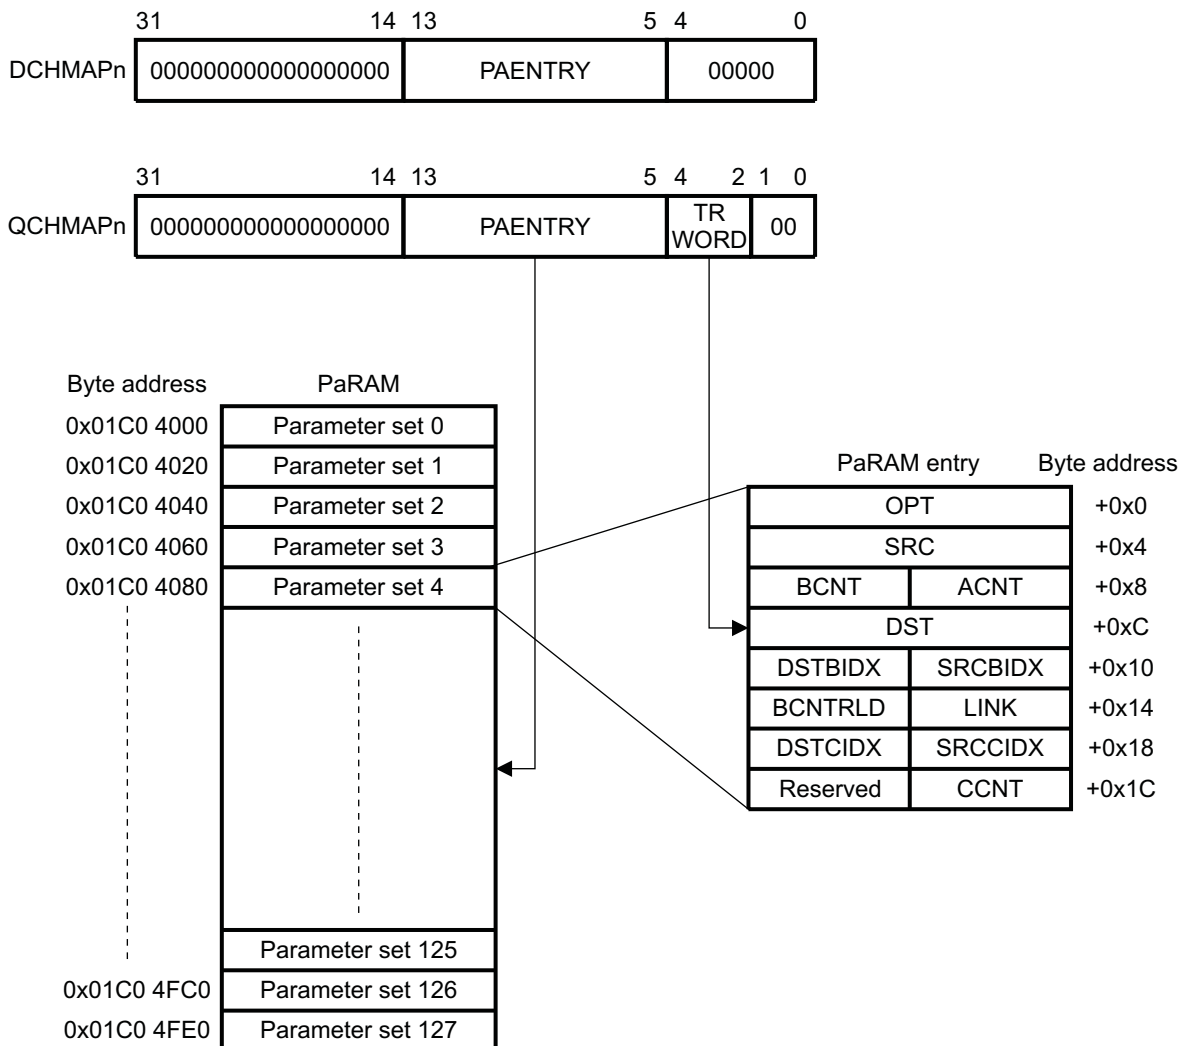

For more information, see [Section 5.4, DSP Subsystem Programming Guide](#).

### 5.3.3.1.3 DMA/QDMA Channel Mapping and PaRAM Entry

The DMA and QDMA channel mapping registers ([TPCC\\_DCHMAPN\\_j](#) and [TPCC\\_QCHMAPN\\_j](#)) allow each DMA and QDMA channel to be mapped to arbitrary locations in the PaRAM memory map. The entry is designated with a 9-bit PAENTRY (the [TPCC\\_DCHMAPN\\_j\[13:5\]](#) PAENTRY and [TPCC\\_QCHMAPN\\_j\[13:5\]](#) PAENTRY bit fields) PaRAM entry number that defines the entry number in a 128-entry maximum PaRAM (see [Figure 5-9](#)). The [TPCC\\_QCHMAPN\\_j\[4:2\]](#) TRWORD bit field points to the trigger word of the PaRAM entry defined by PAENTRY. A write to the trigger word results in a QDMA event being recognized.

[Figure 5-9](#) shows DMA/QDMA channel mapping and PaRAM entry.

**Figure 5-9. DMA/QDMA Channel Mapping and PaRAM Entry**

dsps-013

**NOTE:** Each parameter entry of PaRAM is organized as eight 32-bit words or 32 bytes, as shown in Figure 5-9.

The location of fields in each entry, and the bit positions in the options field, must match the TR packet format as closely as possible to the requirements of the TPTC0 and TPTC1 programming. Each PaRAM entry consists of 16- and 32-bit parameters that correspond to the transfer geometry. For more information about the parameters, see Section 5.3.3.1.2, *DMA Versus QDMA*.

### 5.3.3.1.4 Types of TPCC Transfers

The TPCC streamlines transfers into an orthogonal transfer structure that is always defined by three dimensions. Of the three dimensions, only two synchronization types are supported: 1D synchronized transfers and 2D synchronized transfers; three-dimensional (3D) synchronized transfers can be logically achieved by chaining.

The following terms are used:

- 1D transfer or array: ACNT contiguous byte transfer. For information about the 1D transfer programming model, see Section 5.3.3.1.5, *Transfer Synchronization*.
- 2D transfer or frame: BCNT arrays of ACNT byte transfer. Each array transfer in 2D transfer is

separated from other transfers by an index programmed through the [TPCC\\_BIDX\\_m](#) register.

- 3D or block: CCNT frames of BCNT arrays of ACNT bytes. Each transfer in 3D is separated from the previous transfer by an index programmed by the TPCC\_CIDX register. The reference point for the index depends on the synchronization type.

### 5.3.3.1.5 Transfer Synchronization

In a 1D synchronized transfer, each TPCC TR synchronization triggers the transfer of the first dimension of ACNT bytes, or one array of ACNT bytes. In other words, each TR packet consists of transfer information for only one array. Arrays can be separated by SBIDX and DBIDX (see [Figure 5-9](#)) where the start address of array N equals the start address of array 1 plus SRC or DST BIDX. Frames can be separated by SCIDX and DCIDX. For 1D synchronized transfers, after the frame is exhausted, the address is updated by adding (S|D)CIDX to the beginning address of the last array in the frame.

Contrast this to the (S|D)CIDX update in 2D synchronized transfers, which are referenced from the beginning address of the first array in the previous frame. For information about parameter updates, see [Section 5.3.14, Error Reporting](#).

In a 2D synchronized transfer, each TR synchronization triggers the transfer of two dimensions or one frame. In other words, each TR packet conveys information for one entire frame of BCNT arrays of ACNT bytes. Arrays can be separated by SBIDX and DBIDX (see [Figure 5-11](#)). Frames can be separated by SCIDX and DCIDX. For 2D synchronized transfers, after a TR for the frame is submitted, the address is updated by adding (S|D)CIDX to the beginning address of the beginning array in the frame. Contrast this to the (S|D)BIDX update in 1D synchronized transfers. For information about parameter updates, see [Section 5.3.14, Error Reporting](#).

### 5.3.3.1.6 DMA Channel Prioritization

If multiple trigger sources (event trigger/chain trigger/manual trigger) for a single channel are active at the same time, the TPCC services events in the following order:

1. Event trigger (through the event register [ER])
2. Chain trigger (through the chain event register [CER])
3. Manual trigger (through the event set register [ESR])

### 5.3.3.1.7 Transfer Completion

Transfer completion can be used for two different mechanisms in the TPCC:

- Generating chained events
- Generating interrupts to an external processor

The underlying mechanism for both features is the same. The user programs the PaRAM options field with a specific transfer completion code (the [TPCC\\_OPT\\_m\[17:12\]](#) TCC bit field) and indicates whether that completion code is to be used to generate a chained event and/or an interrupt when a transfer completes. The user can selectively program whether completion signaling is enabled for the final TR of a PaRAM set, for all except the final TR of a PaRAM set, or for all TRs of a PaRAM set. The specific TCC value (6-bit binary value) programmed by the user dictates which bit of the 64-bit CER and/or interrupt pending register (IPR) is used.

There is no direct correlation between the TCC value used for a specific PaRAM entry and the channel number for that entry. Software controls the allocation of TCC values. There is always a 1:1 relationship between the value of the TCC and the IPR bit and/or the CER bit set when that transfer completes. For example, completion of the PaRAM entry for channel 0 can chain-trigger the PaRAM entry for channel 1.

### 5.3.3.2 Third-Party Transfer Controller

The TPTC is the DMA transfer engine that generates transfers as programmed in dedicated working registers, using two dedicated master ports: a read-only port and a write-only port.

---

**NOTE:** The port data bus width of the instances of the TPTC is fixed at 64 bits.

---

### 5.3.3.2.1 TPTC Features

The TPTC features:

- Pipelined transfers (multiple in-flight transfers)
- Background programming
- 2D or 1D transfer
- Increment addressing modes
- Clock-stop handshaking with the SYSC
- Programmable tracking of transfer completion
- 2D qualifications of transfers to allow 2D bandwidth optimization

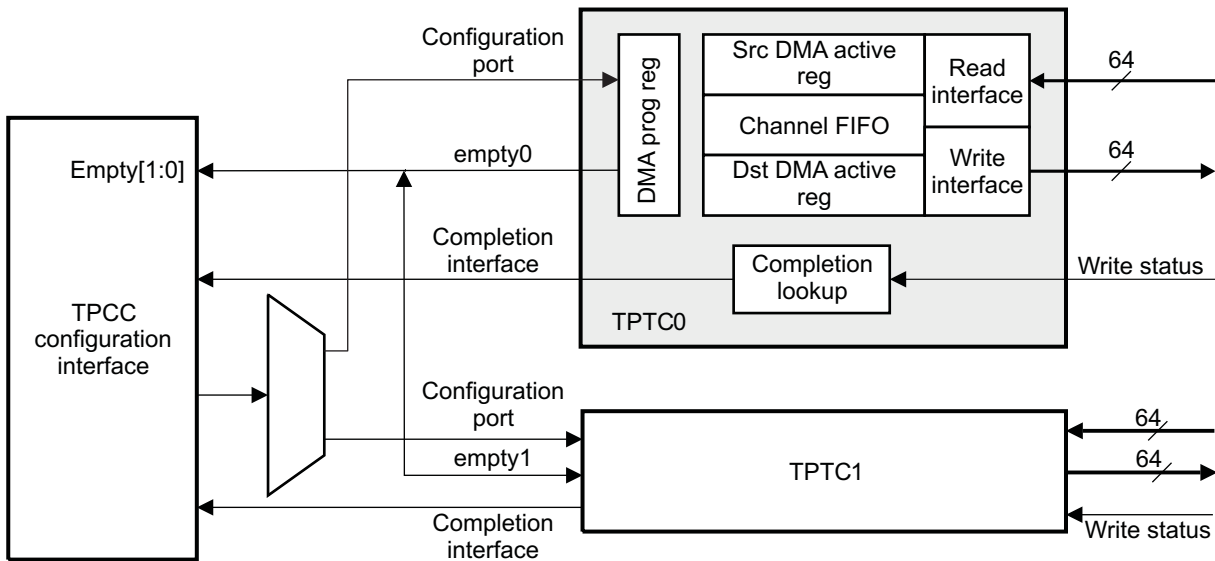

Two instances of the TPTC generate concurrent traffic on the DSP local interconnect. Each TC controller consists of the following components:

- **DMA program register set:** Stores the context for the DMA transfer that is loaded into the active register set when the current active register set completes. The CPU or TPCC programs the program register set, not the active register set. For a typical stand-alone operation, the CPU programs the program register while the TC services the active register set. The program register set includes ownership control that synchronizes the CPU software and the DMA.
- **Source DMA active register set:** Stores the context (src/dst/cnt/, etc.) for the DMA transfer request in progress in the read controller. The active register set is split into independent source and distant register, because the source local interconnect controller and the distant local interconnect controller operate independently of one another.
- **Distant DMA register set:** Stores the context (src/dst/cnt/, etc.) for the DMA transfer request in progress or pending in the write controller. The pending register sets must allow the source controller to begin processing a new TR while the distant register set processes the previous TR.
- **Channel FIFO:** Temporary holding buffer for in-flight data. The read return data of the source peripheral is stored in the data FIFO, and then is written to the destination peripheral by the write command/data bus.
- **Read controller/local interconnect read interface:** The local interconnect read interface issues optimally sized read commands to the source peripheral, based on a burst size of 64 bytes and available landing space in the channel FIFO.
- **Write controller/local interconnect write interface:** The local interconnect write interface issues optimally sized write commands to the destination peripheral, based on a burst size of 64 bytes and available data in the channel FIFO.
- **Completion interface:** Sends completion information to the TPCC for posting interrupts in the TPCC.
- **Configuration port:** Slave interface that provides read/write access to program registers and read access to all memory-mapped TC registers. For information about TPTC registers, see [Section 5.3.1, DSP Subsystem Register Manual](#).

[Table 5-4](#) lists the hardware settings.

[Figure 5-10](#) shows the internal structure of the TPTC and its connection to the TPCC.

Figure 5-10. TPTC Block Diagram

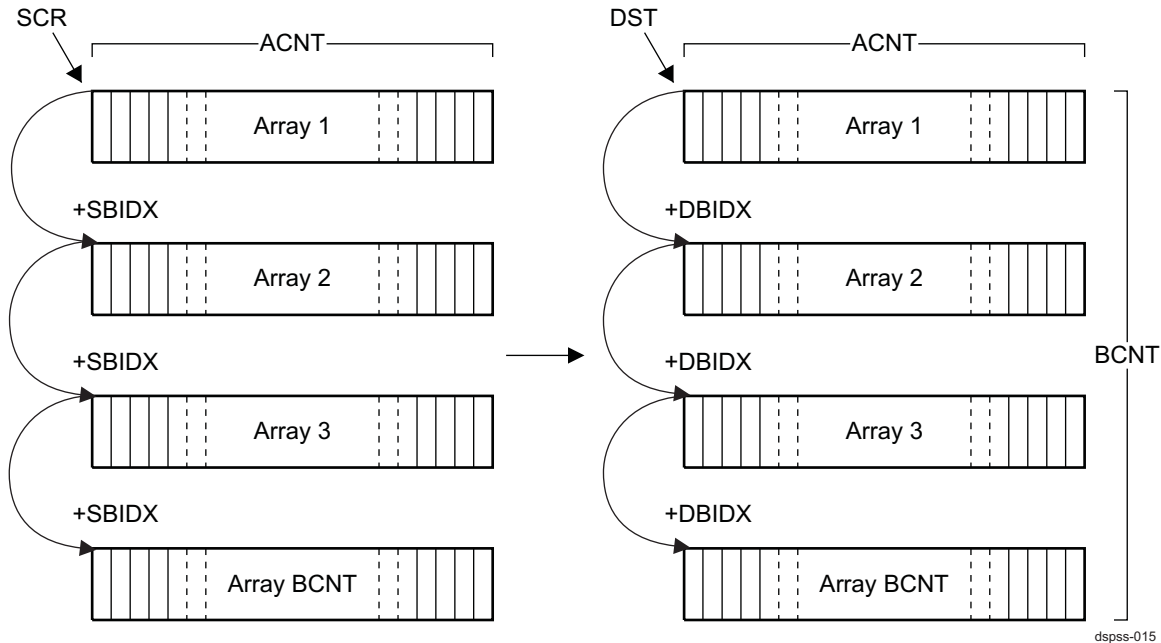

The primary responsibility of the TPTC is to perform read and write transfers through the local interconnect to the slave peripherals, as programmed in the active and program register sets:

- In the TC stand-alone use model, the user directly programs the program and active register sets for a given channel (TPTC0 or TPTC1). Because of the TPCC, this mode is not the use case targeted for device applications; therefore, it is not emphasized in this chapter. For information about its programming model, see [Section 5.4.3.5.5, Direct Configuration to Transfer Channel \(Not Recommended\)](#).
- In the TC external-control use model, the user does not directly program the active and program register sets. Instead, the TPCC is the user interface to the eDMA system, and the TPTCs (TPTC0 and TPTC1) are slaves to the TPCC. This is the use case of the eDMA in device applications.

### 5.3.3.2.2 Transfer Geometry

The TPTC supports a transfer geometry fully defined by the registers summarized here (see [Figure 5-11](#)):

- OPTx: Options, where x = 0 or 1
  - SAM: Source address mode; controls whether the source array is from incrementing addresses or from one FIFO address
  - DAM: Distant address mode; controls whether the destination array is to an incrementing address or to one FIFO address
  - FWID: Controls the width of the FIFO
- SRC: Source address
- DST: Distant address
- CNT: BCNT, ACNT
  - ACNT: Number of bytes in each array
  - BCNT: Number of arrays in each TR
- BIDX: DBIDX, SBIDX
  - SBIDX: Source B-dimension index; defines the address offset between starting addresses of each source array
  - DBIDX: Distant B-dimension index; defines the address offset between starting addresses of each destination array

**Figure 5-11. Transfer Geometry**

dspss-015

**NOTE:** Many TI DMA controllers employ a concept of element size and element indexing. To maintain orthogonality, the concept of element size has been dropped. An element-indexed transfer is logically achieved by programming ACNT to the size of the element, and programming BCNT to the number of elements that must be transferred.

### 5.3.3.2.3 Tracking Transfers

Each TPTC channel consists of three register sets: a program register set and a source-active register set. The status of each of these register sets is indicated by the PROGBUSY, SRCACTV, DSTACTV, and WSACTV status bits, which are user-readable in the [TPTC\\_TCSTAT](#) register.

The program register set ([TPTC\\_POPT](#), [TPTC\\_PSRC](#), [TPTC\\_PCNT](#), [TPTC\\_PDST](#), [TPTC\\_PBIDX](#), and [TPTC\\_PMPPRXY](#)) is never modified by the TPTC, because it is simply holding registers processed by the active register set. The source active register set ([TPTC\\_SAOPT](#), [TPTC\\_SASRC](#), [TPTC\\_SACNT](#), [TPTC\\_SADST](#), [TPTC\\_SABIDX](#), [TPTC\\_SAMPPRXY](#), [TPTC\\_SACNTRLD](#), [TPTC\\_SASRCBREF](#), and [TPTC\\_SADSTBREF](#)) tracks commands for the source side of the transfer.

As the source controller processes a TR, the SRC, DST, and CNT fields must be continuously updated as commands are issued. A reference value for these registers is also maintained. The active register set uses the reference address (SRCBREF and/or DSTBREF) to calculate the addresses of subsequent arrays in a transfer. This is required because subsequent arrays are defined as an offset from the starting address of the current array. Similarly, when a new array begins, the CNT must be restored (from CNTRLD) to the originally programmed value and decremented as the new array is processed.

The following summarizes the use of the active register sets:

- Static fields:
  - OPT
  - BIDX: DBIDX/SBIDX
- Dynamic fields:
  - SRC: Source address of the next read command to be issued
    - Tracked by the source active register set
  - DST: Distant address of the next write command to be issued

- Tracked by the distant FIFO register set
- CNT: BCNT/ACNT
  - BCNT: Number of arrays remaining to be transferred. This includes the current array; that is, BCNT is decremented after all commands for an array are issued (or at least after all read or write commands are scheduled).
  - ACNT: Number of bytes remaining to be transferred
  - Tracked independently in the source and distant FIFO register sets
- Reference fields:
  - CNTRLD: ACNTRLD only
    - CNTRLD.ACNTRLD is set with the initial value of CNT.ACNT. The reload value is copied into CNT.ACNT when CNT.ACNT decrements to 0.
    - Tracked independently in the source and distant FIFO register sets

Because a command is complete when BCNT decrements to 0, there is no reload value for BCNT.

- SRCBREF: Source address reference points to the starting address of the array being read. The starting address of the next array is calculated as SRCBREF + SBIDX.
  - Tracked by the source active register set
- DSTBREF: Distant address reference points to the starting address of the array being written. The starting address of the next array is calculated as DSTBREF + DBIDX.
  - Tracked by the distant FIFO register set

#### 5.3.3.2.4 Completion Interface to TPCC

If TCINTEN or TCCHEN is set to 1, the TPTC must return completion information when the entire TR completes. The TPCC uses the completion information for chaining (enabled by TCCHEN) or posting interrupts (enabled by TCINTEN).

The TPTC generates status conditions based on the completion of a transfer (the [TPTC\\_INTSTAT\[1\]](#) TRDONE bit) and on the program register set transitioning to the downstream registers (the [TPTC\\_INTSTAT\[0\]](#) PROGEMPTY bit).

These two conditions can be enabled by the corresponding bits in the [TPTC\\_INTEN](#) register to generate an interrupt to the DSP CPU through the TCERRINTx interrupt line (TCERRINT0 for TPTC0, and TCERRINT1 for TPTC1). For the event mapping of these interrupt lines, see [Table 5-3](#).

---

**NOTE:** The TRDONE and PROGEMPTY status bits are always available and are stored in the [TPTC\\_INTSTAT](#) register, regardless of the use model and regardless of whether the corresponding bits are enabled. Typically, these bits are used not in the TPCC use model, but in a stand-alone use model in which the user directly programs the TC.

---

For more information about eDMA completion and its programming model, see [Section 5.4.3.1, Transfers From/to Device Memories/Peripherals \(eDMA\)](#).

#### 5.3.3.3 eDMA Hardware Parameters

[Table 5-4](#) lists the hardware parameter settings for the DSP subsystem.

**Table 5-4. eDMA Hardware Parameters**

Module		Parameter	DSP Subsystem
eDMA	TC	FIFO size for TC0	256 bytes
		FIFO size for TC1	128 bytes
		Data bus width	64 bits
		TR pipelining depth TC0	4
		TR pipelining depth TC1	2
		Endianness	Little

**Table 5-4. eDMA Hardware Parameters (continued)**

Module	Parameter	DSP Subsystem
	Burst size	64
CC	Number of DMA channels	64
	Number of QDMA channels	8
	Number of PaRAM entries	128
	Number of Event Qs	2
	Number of TPTCs	2

**NOTE:** The TR pipelining depth controls the number of read TRs for a given transfer channel that can be serviced by the source transfer controller without being serviced by the distant transfer controller. This dictates the amount of storage required in the distant queue channel registers for in-flight TRs.

The user cannot directly program burst size, as with the system DMA (sDMA), but must rely on the ACNT/BCNT and issue 1D synchronization transfers to do so.

### 5.3.4 MMU

The DSP MMU communicates accesses from the DSP core of the DSP subsystem to the L3 interconnect, mapping the 4GB of the DSP virtual addresses to any place in the 4-GB address space of the device.

At reset, the MMU is disabled, and the DSP CPU can access global memory mapping in the device from the 0x1100 0000 address. Addresses in the range of 0x0000 0000 to 0x10FF FFFF can be reached only by the DSP CPU, because it performs its own internal memory mapping. For more information, see [Section 2.2, L3 Memory Space Mapping](#) in [Chapter 2, Memory Mapping](#).

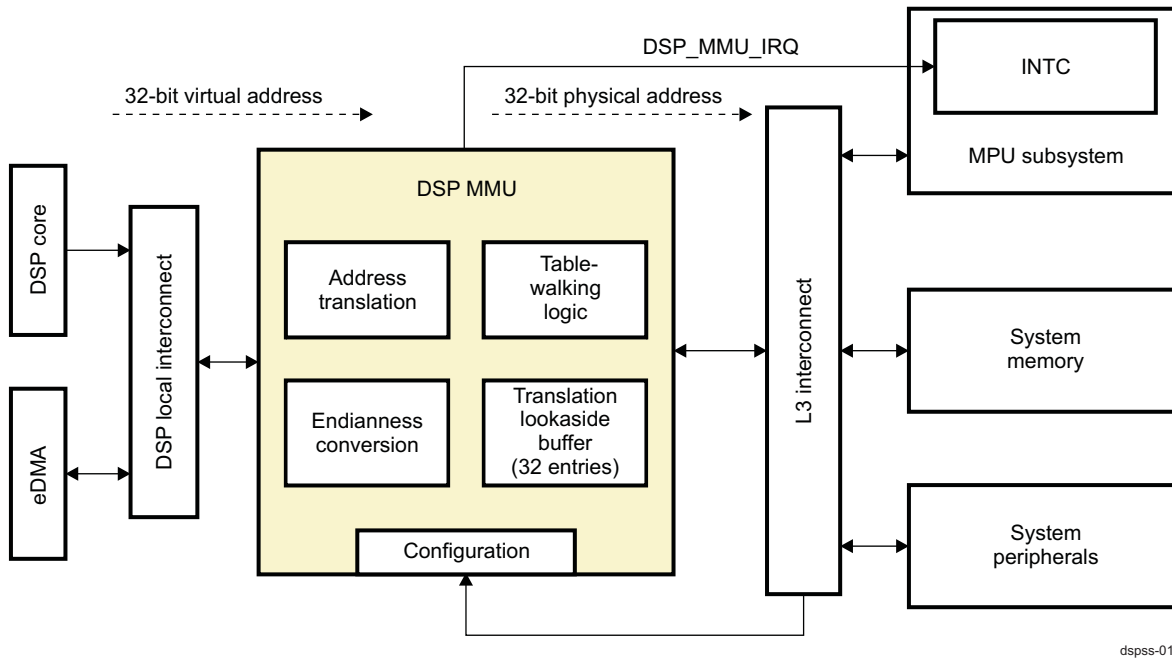

The DSP MMU features:

- 32 entries/fully associative translation lookaside buffer (TLB)
- One interrupt line to the MPU
- 32-bit virtual addresses, 32-bit physical addresses
- 4-KB, 64-KB, 1-MB, and 16-MB pages
- Predefined (static), software-driven (interrupt-based), or table-driven (hardware table-walker) software translation strategies
- 2-level descriptor hierarchy
- One intermediate page table
- Fault status and fault address register

**NOTE:** The endianness conversion capability of the MMU is not used in the DSP subsystem (the DSP is configured as a little-endian processor in the device). With this configuration, the setting of the MMU\_RAM[9] ENDIANNES bit is ignored, even if the user changes the value. For more information, see [Chapter 20, Memory Management Units](#).

[Figure 5-12](#) shows the integration and functionality of the DSP MMU.

Figure 5-12. DSP MMU Block Diagram

### 5.3.4.1 MMU VA-to-PA Translation

The DSP MMU translates the 32-bit DSP external addresses to physical addresses in the 32-bit MPU address space. Address translation is performed by a translation table base (TTB) structure that maps the most-significant bits (MSBs) of the DSP byte address to another set of MSBs of a 32-bit MPU byte address. The least-significant bits (LSBs) of the DSP-generated byte address are used as page/section indices in the address translations and are not altered when forming the new 32-bit physical address. The TTB translations are expedited by a TLB that serves as a cache of recently used page translations. The address mapping can be programmed at the TTB level or by writing the TLB entries directly. The DSP MMU contains 32 TLB entries that can be configured to remap 4-KB, 64-KB, 1-MB, or 16-MB segments of memory.

The TLB can be managed statically or dynamically (through the use of interrupts) by the MPU OS, but the MMU also includes hardware table-walking logic that lets the MMU autonomously traverse the page table on a TLB miss. On a TLB miss, the translation table-walking logic automatically retrieves the information from the translation table stored in physical memory and updates the TLB cache.

Figure 5-13 shows the TTB structure in detail.

**Figure 5-13. DSP MMU Translation Table Hierarchy**

**NOTE:** The MMU passes the lower bits of the virtual address unchanged.

### 5.3.4.2 MMU Configuration

If the DSP MMU requires software intervention, the MPU services the event; DSP MMU service requests are signaled to the MPU with a dedicated interrupt (see [Table 5-3](#)).

Generally, the MMU is initialized at boot time, but it can also be dynamically reprogrammed. Typically, the MMU is programmed by the device MPU through the DSP slave L4 port on the L3 interconnect when a new task is created on the DSP subsystem. However, the DSP also has access to the MMU configuration registers for the save-and-restore process. At reset, the MMU is disabled and DSP virtual addresses are passed directly through as physical addresses (not translated).

For more information about the functions of the MMU in the DSP subsystem, including interrupts, register descriptions, and programming model, see [Chapter 20, Memory Management Units](#).

### 5.3.5 Clock Configuration

The DSP subsystem receives one clock signal from the PRCM module (see [Table 5-2](#)).

Generation of these clocks is handled internally to the DSP subsystem by the SYSC module under direct control of the PRCM module.

[Table 5-5](#) lists the clock domains in the DSP subsystem and the roles of the clocks.

**Table 5-5. DSP Internal Clock**

Clock Domain	Clock	Description
CD0	CD0_CLK	DSP core + PMC + DMC + L1/L2 caches + SCTM
CD1	CD1_CLK	Power-down logic (WUGEN) + INTC + external interfaces + DSP megamodule external interfaces + local interconnect + eDMA + MMU + SYSC

**NOTE:** The internal clocks can be shut down by the PRCM module after the handshake protocol is complete. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

### 5.3.6 Hardware and Software Resets

#### 5.3.6.1 Hardware Resets

See [Table 5-2](#) for more information on the following reset signals:

- DSP\_RST: Connected to the DSP megamodule and the eDMA module
- DSP\_WGN\_RST: Connected to the DSP subsystem WUGEN module
- DSP\_RET\_RST: Connected to most of the blocks of the DSP subsystem. It resets the DSP subsystem logic, including the cache valid bits, cache enable bits, DSP INTC, and some registers in the DSP MMU.
- DSP\_PWRON\_RST: Performs a power-on initialization of the DSP subsystem logic

After chip power on, the DSP subsystem is kept under reset and only the DSP\_RET\_RST signal is released from reset. Then, only the WUGEN is released from reset as part of the CORE power domain. The DSP subsystem remains under reset until the MPU clears the DSP reset bit (see [Reset Domains](#) in [Chapter 3, Power, Reset, and Clock Management](#)). On this action, the PRCM module switches on the DSP power domain, sets the clocks back, and releases the power-on reset (POR). When the DSP power-on sequence completes (hardware handshake), the PRCM module releases the reset signal. At this stage, the DSP megamodule is kept under reset; the MPU can upload some code and data in the C64x+ memory. When the MPU has uploaded the code in the C64x+ memory, it releases the DSP megamodule from reset. At this point, the sequencer is kept under reset; the DSP can upload some code and data in the sequencer memory. When the DSP has uploaded the code in the sequencer memory, the DSP releases the sequencer from reset.

#### 5.3.6.2 Software Resets

DSP subsystem reset signals are sourced from the PRCM module. Some modules of the DSP subsystem can also be reset by software control.

The MPU can apply a software reset to the DSP. For a software reset to be safe, the DSP subsystem must be in clock-off mode (DSP is in idle mode with clocks shut down by the PRCM module; for information about the clock-off state transition, see [Section 5.4.6.3, Power-Down and Wake-Up Management](#)). For instance, the MPU can use a mailbox interrupt to ask the DSP subsystem to go into IDLE state.

The DSP subsystem can also program the PRCM module to go into OFF state automatically when it is idle. Then, in response to a wake-up event (for example, an interrupt), the PRCM module can switch on the DSP power domain, set the clocks back, and release POR. When the DSP power-on sequence completes (hardware handshake), the PRCM module releases the reset signals. However, for the IDLE instruction (to transition to OFF state) to be executed, the user must program the PRCM module to prevent the sequencer from being released from reset after a wakeup of the DSP from POWER OFF state.

For some detected severe issues or if the user applies an external system reset, the DSP can receive a warm reset. All reset signals except POR are applied.

For more information on the DSP reset bits, see , *PD\_DSP Description*, in [Chapter 3, Power, Reset, and Clock Management](#).

---

**NOTE:** Software reset can be applied only while the DSP subsystem is in clock-off mode.

---

The WUGEN reset signal (DSP\_WGN\_RST) is reset with the CORE power domain, which is reset when global cold or global warm reset events occur. For more information about global reset sources, see , *Reset Domains* in [Chapter 3, Power, Reset, and Clock Management](#).

For more information about software resets, see [Section 5.4.6.2, Reset Management](#).

### 5.3.7 Interrupt Requests

The DSP subsystem manages three types of interrupts (see [Figure 5-14](#)):

- Internal interrupts: Requests generated by modules in the DSP subsystem or in the DSP megamodule
- External interrupts: Requests generated by peripherals external to the DSP subsystem, such as serial port interface (SPI), display subsystem, or camera subsystem. Peripherals that generate interrupts at the DSP level use the D\_IRQ\_k input lines of the DSP subsystem.
- MMU interrupt: The DSP MMU can generate an interrupt to an external host outside the DSP subsystem. As shown in [Figure 5-2](#), the interrupt line of the MMU (DSP\_MMU\_IRQ) is connected to the MPU INTC.

For more information about the functions of the DSP MMU, see [Section 5.3, DSP Subsystem Functional Description](#).

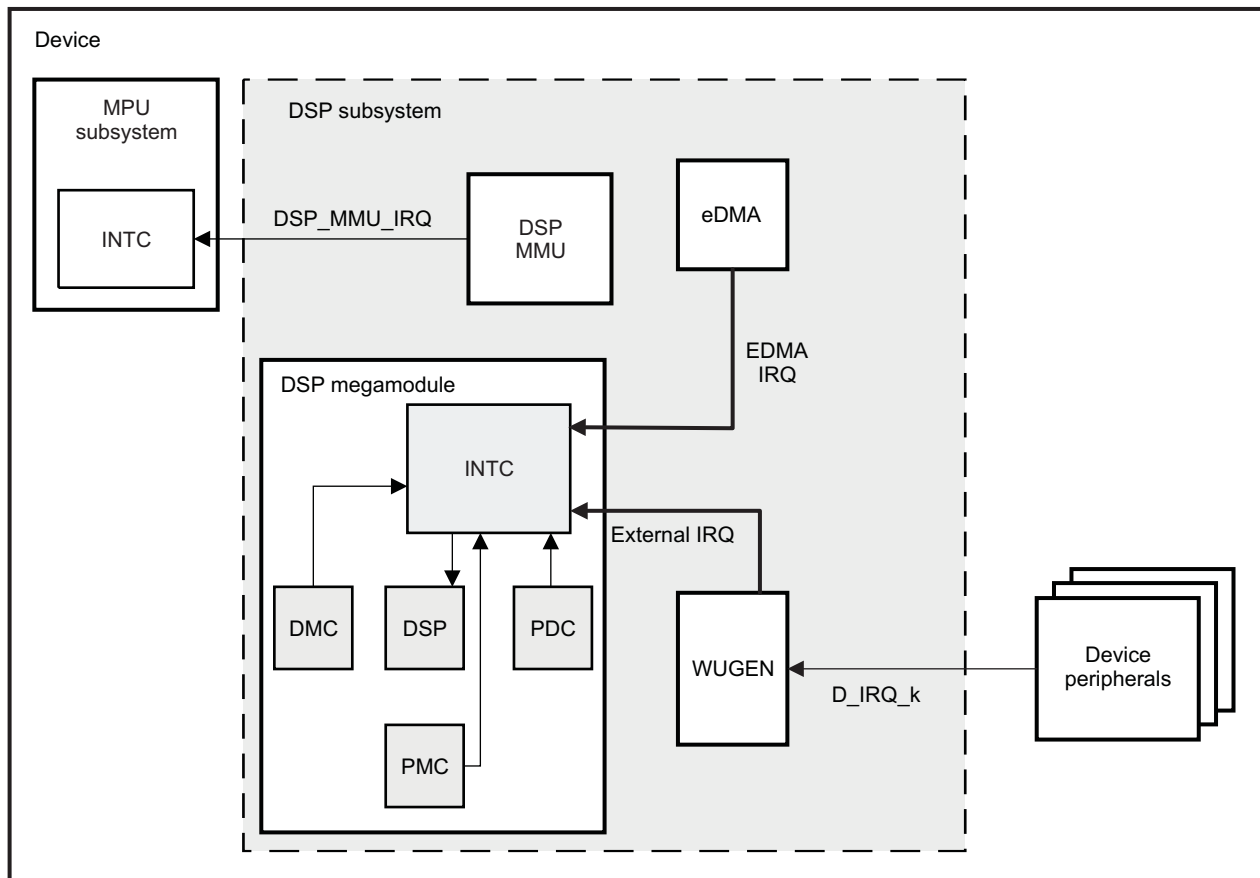

To manage and expand the interrupt capabilities of the DSP megamodule (internal and external interrupt requests), the DSP subsystem includes two levels of interrupt control (see [Figure 5-14](#)):

- One INTC, integrated in the DSP megamodule. This module controls all interrupt requests (internal and external), except the MMU interrupt.

For more information about the INTC, see [Section 5.3.2.6, INTC](#).

- One WUGEN: Responsible at the DSP subsystem level for detecting wake-up events (interrupts, DMA requests, and slave port access) when the DSP subsystem is powered down. The WUGEN also handles formatting interrupts from device peripherals to the DSP megamodule INTC.

Figure 5-14. DSP Subsystem Interrupt Management

dspss-006

In addition to interrupt sources internal to the DSP subsystem, several interrupt sources coming from device peripherals are connected to the DSP megamodule INTC, but not directly.

These external interrupt sources are resynchronized in the WUGEN, synchronously with the CD1\_CLK clock, and then they are connected to the INTC.

Table 5-6 lists the global interrupt mappings of the DSP subsystem.

Table 5-6. DSP Interrupt Mappings

EVT	Interrupts/Events	DSP Subsystem Pin Name	Interrupt Source	Description
D_IRQ_0	EVT0	N/A (internal)	DSP INTC	Output of event combiner 0, for events 4-31
D_IRQ_1	EVT1	N/A (internal)	DSP INTC	Output of event combiner 1, for events 32-63
D_IRQ_2	EVT2	N/A (internal)	DSP INTC	Output of event combiner 2, for events 64-95
D_IRQ_3	EVT3	N/A (internal)	DSP INTC	Output of event combiner 3, for events 96-127
D_IRQ_4-8	Reserved	N/A (internal)	DSP INTC	Reserved
D_IRQ_9	EMU_DTDMA	N/A (internal)	DSP INTC	ECM interrupt (host scan access, DTDMA)
D_IRQ_10-14	Reserved	N/A (internal)	DSP INTC	Reserved
D_IRQ_15	ABE_DSP_IRQ	D_WUGEN_0	DSP INTC	ABE interrupt
D_IRQ_16	MMC1_IRQ	D_WUGEN_1	DSP INTC	MMC/SD module 1 (L3 initiator)
D_IRQ_17	MMC2_IRQ	D_WUGEN_2	DSP INTC	MMC/SD module 2 (L3 initiator)

**Table 5-6. DSP Interrupt Mappings (continued)**

EVT	Interrupts/Events	DSP Subsystem Pin Name	Interrupt Source	Description
D_IRQ_18	Reserved	D_WUGEN_3	DSP INTC	Reserved
D_IRQ_19	Reserved	D_WUGEN_4	DSP INTC	Reserved
D_IRQ_20	Reserved	D_WUGEN_5	DSP INTC	Reserved
D_IRQ_21	Reserved	D_WUGEN_6	DSP INTC	Reserved
D_IRQ_22	Reserved	D_WUGEN_7	DSP INTC	Reserved
D_IRQ_23	Reserved	D_WUGEN_8	DSP INTC	Reserved
D_IRQ_24	Reserved	D_WUGEN_9	DSP INTC	Reserved
D_IRQ_25	Reserved	D_WUGEN_10	DSP INTC	Reserved
D_IRQ_26	ELM_IRQ	D_WUGEN_11	DSP INTC	Error location process completion

The interrupts generated by the WUGEN (interrupts from device peripherals) are programmable using a set of registers accessible by the user.

Events related to these external interrupts can be masked by writing to registers [WUGEN\\_MEVTSET0](#) through [WUGEN\\_MEVTSET4](#). The interrupts can also be individually unmasked by using registers [WUGEN\\_MEVTCCLR0](#) through [WUGEN\\_MEVTCCLR4](#). By default (after power on), these external interrupts are masked in the WUGEN.

All other interrupts are directly managed by the DSP INTC, and the DSP registers are set. For information about the DSP INTC, see the documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).

### 5.3.8 DMA Requests

The DSP subsystem receives DMA requests from specific peripherals, such as the multichannel buffered serial port (McBSP) module and the universal asynchronous receiver/transmitter (UART) module (see [Figure 5-15](#)).

**Figure 5-15. DSP eDMA Requests**

dspss-005

For a description of the eDMA controller, see [Section 5.3.3, eDMA](#).

For the eDMA request mappings to the DSP subsystem eDMA controller, see [Table 5-3](#).

**NOTE:** All eDMA requests are shared DMA requests, and they are mapped on the sDMA. For more information, see [, sDMA Basic Programming Model in Chapter 16, sDMA](#).

For more information about eDMA request management, see [Section 5.4.3.2, Programming an eDMA Transfer](#).

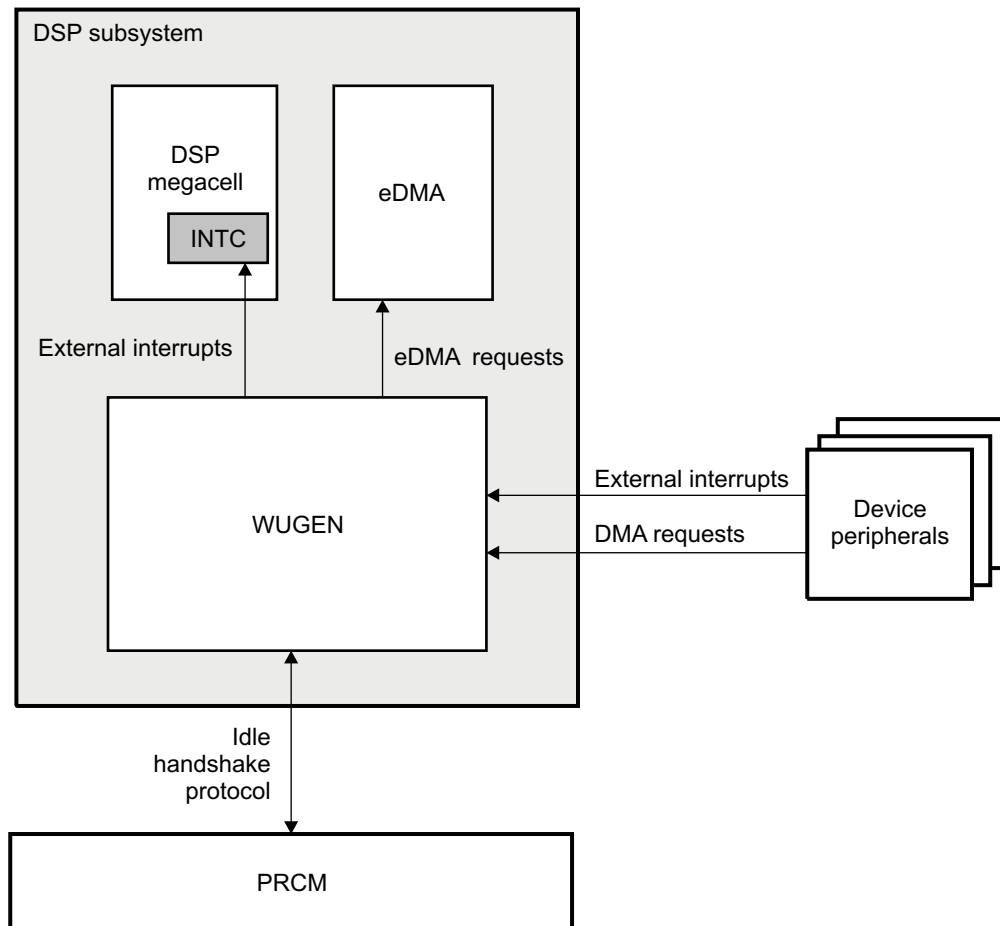

### 5.3.9 Wake-Up Generator

The WUGEN controls the following:

- Implementing the DSP idle handshake protocol with the PRCM module
- Resynchronizing interrupts and DMA requests from device peripherals external to the DSP subsystem
- Blocking the interrupts and DMA requests to the DSP on clean boundaries, when the WUGEN is asked to go into IDLE state
- Detecting the enabled wake-up interrupts and DMA requests and generating a wake-up event to the PRCM module
- Formatting interrupts to the DSP megamodule interrupt format

[Figure 5-16](#) shows the WUGEN in the DSP subsystem and its interactions with other submodules.

**Figure 5-16. DSP WUGEN Description**

dsps-030

### 5.3.9.1 Interrupts, DMA Requests, and Event Management

Interrupts and DMA requests are generated in the same way in the WUGEN. In this section, both are called events.

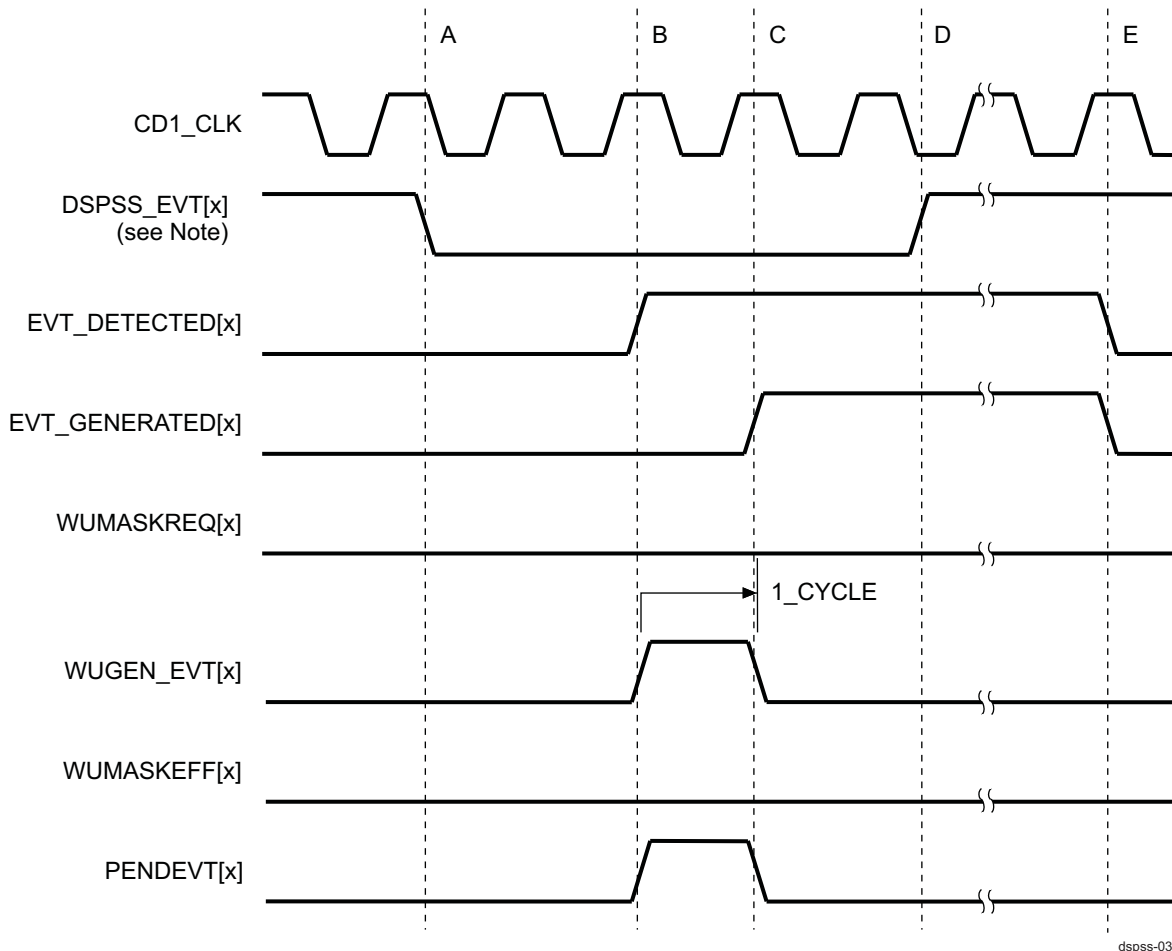

To manage interrupts, DMA requests, and slave port accesses from external modules, the WUGEN uses several sets of user-programmable registers:

- The [WUGEN\\_MEVT0](#) through [WUGEN\\_MEVT4](#) registers define individual mask bits for external asynchronous events (interrupts, DMA requests, and slave port access). This register is read-only, accessible only by the DSP. To modify the value of the individual mask, write 1 to the associated bits of the [WUGEN\\_MEVTCLR0](#) through [WUGEN\\_MEVTCLR4](#) registers (to clear) and to the [WUGEN\\_MEVTSET0](#) through [WUGEN\\_MEVTSET4](#) registers (to set).
- [WUGEN\\_PENDEVT0](#) through [WUGEN\\_PENDEVT4](#) are read-only registers that track which external events are pending in the WUGEN and are not yet generated to the DSP megamodule INTC or eDMA. If an event is masked, this information is stable until the corresponding mask bit is cleared. If an event is unmasked, this information may not be stable, and therefore corresponds to a transitive period of processing the event in the WUGEN.

#### 5.3.9.1.1 Event Generation

[Figure 5-17](#) shows event-generation steps in the WUGEN.

Figure 5-17. WUGEN Event Generation

dspss-031

- A An asynchronous event is asserted.
- B The event is resynchronized and detected. Because the event is not masked, it is propagated to the DSP megamodule or eDMA.
- C The event-pending flag is cleared because the event was generated. The event to the DSP megamodule or eDMA is deasserted after one WUGEN clock cycle.
- D After a period of time, the source of the event is released (probably because it cleared in the corresponding interrupt status register).
- E The release of the event is detected and clears the internal EVT\_GENERATED flag for that interrupt.

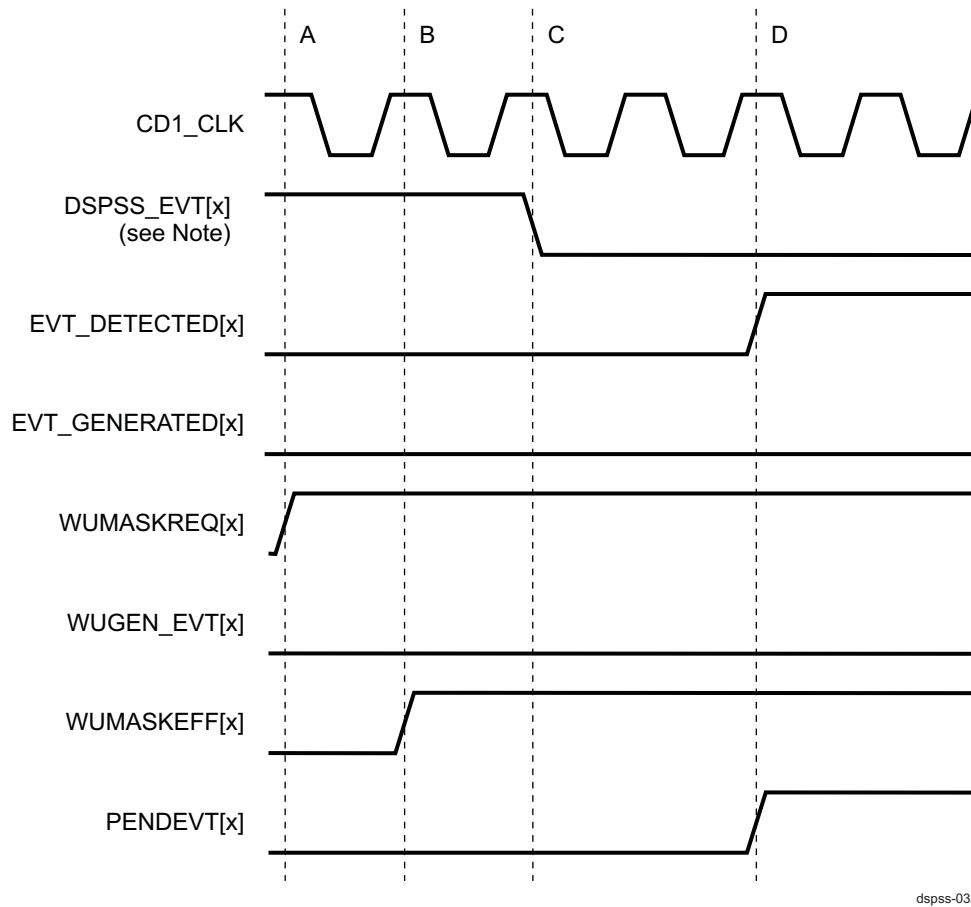

**NOTE:** DSPSS\_EVT[x] refers to DSPSSnIRQ[x] or DSPSS\_nDMAREQ[x].

### 5.3.9.1.2 Individual Event Masking

To mask individual events, write 1 in the [WUGEN\\_MEVTSET0](#) through [WUGEN\\_MEVTSET4](#) registers of the WUGEN. These registers are used to mask interrupts and DMA requests.

[Figure 5-18](#) shows event masking in the WUGEN.

**Figure 5-18. WUGEN Event Masking**

- A The user sets the corresponding bit in the mask. Event generation is disabled.
- B Completion of the event mask is shown in reads of the [WUGEN\\_MEVT0](#) through [WUGEN\\_MEVT4](#) registers.
- C An asynchronous event is asserted.
- D The event is resynchronized and detected. Because the event is masked, it is not propagated to the DSP megamodule or eDMA. The event-pending flag is kept active (sticky) until the mask is removed.

---

**NOTE:** DSPSS\_EVT[x] refers to DSPSS\_nIRQ[x] or DSPSS\_nDMAREQ[x].

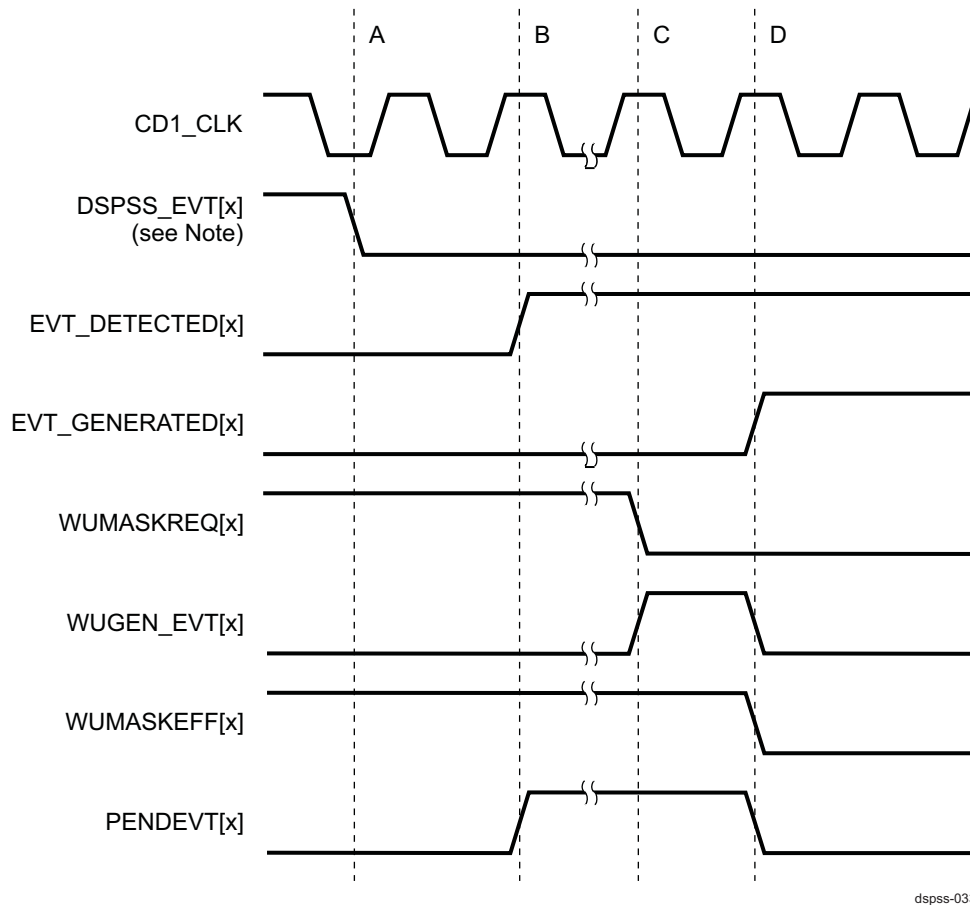

---

### 5.3.9.1.3 Individual Event Mask Clear

To unmask individual events, write 1 in the [WUGEN\\_MEVTCLR0](#) through [WUGEN\\_MEVTCLR4](#) registers of the WUGEN.

[Figure 5-19](#) shows event-mask-clearing in the WUGEN.

Figure 5-19. WUGEN Event Mask Clear

dspss-033

- A An asynchronous event is asserted.
- B The event is resynchronized and detected. Because the event is masked, it is not propagated to the DSP megamodule or eDMA. The event-pending flag is kept active (sticky) until the mask is removed.
- C After a period of time, clear the corresponding bit in the WUGEN mask. The event is automatically generated to the DSP megamodule if the event is still seen as active. If the event is not seen as active, nothing happens.
- D In both of the previous cases, the event-pending flag is cleared.

**NOTE:** DSPSS\_EVT[x] refers to DSPSS\_nIRQ[x] or DSPSS\_nDMAREQ[x].

For more information about interrupts and the eDMA programming model, see [Section 5.4.4, Interrupt Management](#), and [Section 5.4.3.1, Transfers From/to Device Memories/Peripherals \(eDMA\)](#).

### 5.3.9.2 Idle Handshake

After reset, the WUGEN waits for a request. If the user executes the DSP IDLE instruction to put the DSP in STANDBY state, the SYSC initiates a clock-off handshake with the WUGEN.

### 5.3.10 SYSC Module

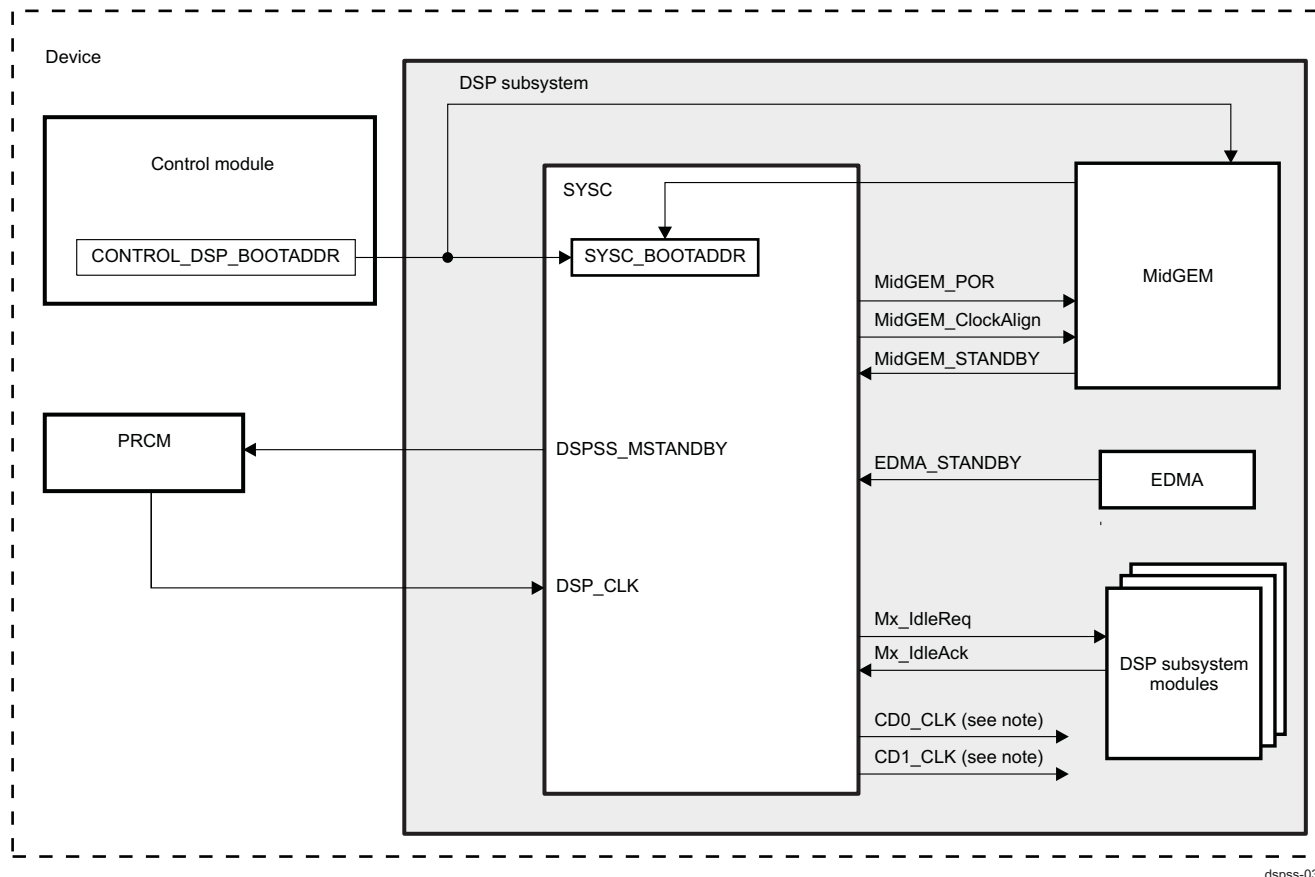

The SYSC module of the DSP subsystem controls the following functions:

- Generation of the divided clocks to all components of the DSP subsystem
- Synchronization of the DSP divided clocks and the DSP megamodule internal-divided clocks
- PRCM module power handshaking
- Sequencing of clock-to-off transition for the DSP modules

- Reset input resynchronization of the active-to-inactive transition to the CD1\_CLK clock
- DSP subsystem boot configuration and its access from the DSP

Figure 5-20 is the block diagram of the SYSC in the DSP subsystem.

**Figure 5-20. SYSC Block Diagram**

dsps-034

**NOTE:** For more information, see [Section 5.3.5, Clock Configuration](#).

### 5.3.10.1 Divided Clock Generation

The SYSC module generates the divided clocks used by the modules in the DSP subsystem. The SYSC generates the following clocks:

- CD0\_CLK
- CD1\_CLK

Based on the DSP\_FCLK clock, these clocks are configured from the PRCM module. For details, see [Section 5.3.5, Clock Configuration](#).

### 5.3.10.2 Clock Management, Power Down, and Wakeup

The SYSC ensures correct generation of the clocks described in [Figure 5-20](#). The SYSC also allows management of the clock gating of the eDMA and DSP megamodule if the user wants to lead some dynamic power aspects.

The SYSC controls the transition to the DSP subsystem STANDBY state and standby signal generation (the DSPSS\_MSTANDBY signal in [Figure 5-20](#)) to the PRCM module. Using the signals DSP\_MEGACELL\_STANDBY, EDMA\_STANDBY, Mx\_IdleReq, and Mx\_IdleAck, the SYSC manages and controls the correct power-down transition of the DSP subsystem and its submodules to ensure that the DSP subsystem internal clocks can be cut. For information about the DSP power-down transition and its programming model, see [Section 5.4.6.3, Power Down and Wakeup Management](#).

External events can also occur at the DSP subsystem boundary (access to the DSP subsystem using the slave access port or external nonmasked events), requiring the restart of the DSP subsystem clocks (in case of DSP subsystem STANDBY state). The WUGEN controls the asynchronous generation of a wake-up signal to the PRCM module; this signal restarts DSP phase-locked loop (PLL) clock generation, allowing the SYSC to regenerate the DSP subsystem internal clocks.

### 5.3.10.3 Boot Configuration

[SYSC\\_BOOTADDR](#) is the boot-time configuration register. This read-only register is accessible only by the DSP, and its value is determined when the DSP subsystem is released from reset by the PRCM module.

The value of this register is driven externally by the system control module (SCM) register (CONTROL.CONTROL\_DSP\_BOOTADDR), which is read-write accessible by the MPU subsystem for MPU-driven DSP subsystem boot sequence and/or by the DSP for autonomous boot. For more information, see [Section 5.4.1, DSP Boot](#).

---

**NOTE:** If the values of the CONTROL.CONTROL\_DSP\_BOOTADDR register change, the values of the new [SYSC\\_BOOTADDR](#) register are not updated until the next reset.

---

For more information, see [Section 5.4.1, DSP Boot](#).

### 5.3.10.4 Interconnect Optimization

[SYSC\\_VBUSM2OCP](#) is a local interconnect configuration register. It is read-write accessible only by the DSP. Setting this register enables or disables interconnect optimization.

### 5.3.11 Local Memories

The DSP subsystem integrates the following memory controllers under the control of the DSP megamodule:

- Data memory controller (DMC)
- Program memory controller (PMC)

Depending on the software configuration of these memory controllers, local memories in the DSP subsystem can be used as cache or memory-mapped memories.

---

**NOTE:** When locking, the cache memory acts as if it is a memory-mapped memory. For more information about cache maintenance, see [Section 5.4.2.2.3.1, Maintenance of Caches](#).

---

[Figure 5-21](#) shows the memory hierarchy of the DSP subsystem.

**Figure 5-21. DSP Local Memories Hierarchy**

dspss-035

### 5.3.11.1 L1/L2 shared cache Overview

The following features are supported by the shared cache controllers:

- 32-KB L1 unified cache implemented with high-performance bit cell to run at full-speed
- 128-KB L2 unified cache implemented with high-density bit cell to optimize area at half-speed
- L1 cache is 32B line size, 4-way set-associative, and organized as 16-bank.
- L2 cache is 32B line size and 8-way set associative.
- L1 cache supports snooping.
- L2 cache slave port to support snooping from eDMA accesses
- Fully pipelined, supports critical-word-first
- Supports write-combining
- Fill and eviction buffers. Supports hit in fill buffer.
- Dynamic sizing, I/D allocation
- Prefetch 4 lines, preload N lines
- Background preload and clean

For information about the software programming model for cache management of the local RAM memories of the DSP subsystem, see [Section 5.4.2, Cache Management](#).

### 5.3.12 SCTM

The SCTM is a generic profile counter and timer module that provides the following functions:

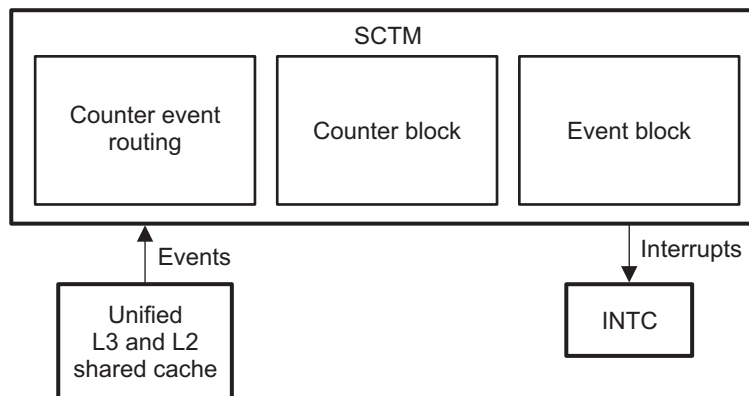

- Counter functions:

- Input events counting
- Two counter modes:
  - Event counting
  - Duration counting
- Counter chaining
- Timer functions:
  - Periodic intervals generation
  - Two timer modes:
    - Run once mode
    - Restart mode
  - Events and/or interrupt generation

The SCTM has eight counters (two of which have timer functions). There are input events going into the SCTM and interrupt events going to the INTC. For more information about the counter configuration and the SCTM input events, see [Section 28.6.3, DSP Subsystem Performance Monitoring](#), in [Chapter 28, On-Chip Debug Support](#). For more information about the interrupt event signals, see [Section 5.3.7, Interrupt Requests](#).

[Figure 5-22](#) shows the SCTM block diagram.

**Figure 5-22. SCACHE SCTM Block Diagram**

dsps-041

### 5.3.12.1 Counter Functions

#### 5.3.12.1.1 Input Events

Signals from within the subsystem are routed to the SCTM and used to control the counters and timers in the module. The routing of the input events from the module boundary to an individual counter is accomplished through an input event multiplexer and is controlled by the [SCACHE\\_SCTM\\_CTCR\\_WT\\_i\[20:16\] INPSEL](#) and [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j\[20:16\] INPSEL](#) bit fields.

---

**NOTE:** For more information about input events to the module boundary, see [Section 28.6.2.2, Cache Events](#), in [Chapter 28, On-Chip Debug Support](#).

---

#### 5.3.12.1.2 Counters

There are individual 32-bit counters in the SCTM. The counters count when the input event signals are asserted.

### 5.3.12.1.2.1 Counting Modes

The counters in the SCTM support two mutually exclusive counting modes:

- Event mode: The counter increments each time a rising edge is detected on the designated input event signal.
- Duration mode: The counter continually increments when the event input is asserted.

### 5.3.12.1.2.2 Counter Overflow

When the counter reaches the terminal value (0xFFFFFFFF) it wraps and continues to increment. This is considered a timer overflow condition. The [SCACHE\\_SCTM\\_CTCR\\_WT\\_i\[6\]](#) OVRFLW and [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j\[6\]](#) OVRFLW bits indicate that overflow has occurred. The overflow bit can be cleared by reading it. When chained, only the high-order counter overflows.

### 5.3.12.1.2.3 Counters and Processor State

The counters can be configured to alter their behavior based on the state of the CPU. The [SCACHE\\_SCTM\\_CTCR\\_WT\\_i\[4\]](#) FREE and [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j\[4\]](#) FREE bits determine whether the counter will continue to operate when the processor enters debug halt state. When the FREE bit is set to 0, the counter stops incrementing while the debug halt input from the CPU is asserted. Normal operation resumes when the processor exits the debug halt state and the debug halt input is deasserted. When the FREE bit is set to 1, the state of the debug halt input is not used to control counter operation.

The [SCACHE\\_SCTM\\_CTCR\\_WT\\_i\[5\]](#) IDLE and [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j\[5\]](#) IDLE bits determine whether the counter will continue to operate when the processor enters idle state (the processor is no longer executing instructions and is waiting for a wake-up event). When the IDLE bit is set to 0, the counter stops incrementing while the idle input from the CPU is asserted. Normal operation resumes when the processor exits the idle state and the idle input is deasserted. When the IDLE bit is set to 1, the state of the idle input is not used to control counter operation.

### 5.3.12.1.2.4 Chaining Counters

The individual 32-bit counters in the SCTM can be chained with an adjacent counter to form a 64-bit counter. Counters chained to a counter across an even-odd index boundary with the even counter contain the least-significant 32 bits of the 64-bit pairing. For example, counters 1 and 0 can be paired and counter 1 will contain bits 63:32 and counter 0 will contain bits 31:0. The high-order counter increments by 1 each time the low-order counter wraps.

Counters are chained by setting the [SCACHE\\_SCTM\\_CTCR\\_WT\\_i\[2\]](#) CHAIN or [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j\[2\]](#) CHAIN bit for both counters. When chained, the counter control for both counters is taken from the [SCACHE\\_SCTM\\_CTCR\\_WT\\_i](#) or [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j](#) register of the low-order counter. Other than the CHAIN bit, all other bits in the high-order [SCACHE\\_SCTM\\_CTCR\\_WT\\_i](#) or [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j](#) register are ignored.

Chained counters can function only in counter mode. Timer mode is not supported.

The [SCACHE\\_SCTM\\_CTCR\\_WT\\_i\[7\]](#) CHNSDW and [SCACHE\\_SCTM\\_CTCR\\_WOT\\_j\[7\]](#) CHNSDW bits are used to indicate that a counter can provide atomics accessed when chained. These bits are valid only for counters with even indexes (the lower half of a 64-bit counter pair). When these bits are set, the counter can shadow the value of the lower half of the chained counter value at the same time the upper half of the counter is read. The shadowed value (not the current value) is returned when the value of the low-order counter is read. Therefore, when a chained counter has atomic read capability, an atomic counter value can be obtained simply by reading the high-order counter first, followed by the low-order counter. This order must always be observed to prevent reading stale counter values from the low-order counter. When counters are functioning independently, the shadow feature is deactivated and a read of the counter always returns the current value.

### 5.3.12.1.2.5 Enabling and Disabling Counters

After the counter is correctly configured, it can be started by setting the `SCACHE_SCTM_CTCR_WT_i[0]` ENBL or `SCACHE_SCTM_CTCR_WOT_j[0]` ENBL bit. At this point, the counter begins incrementing under the control of the configured event input. The counter can be disabled (counting stops) at any time by clearing the ENBL bit. Counters can be enabled and disabled dynamically during application flow.

Counters can also be enabled and disabled as groups through the `SCACHE_SCTM_CTGNBL` register. This register provides control of the individual counter-enable in groups. This allows an application to enable or disable groups of counters in lockstep by setting corresponding bits to 1 (bit number corresponds to counter number).

### 5.3.12.1.2.6 Resetting Counters

The counters can be reset to their initial value (0x00000000) by writing 1 to the `SCACHE_SCTM_CTCR_WT_i[1]` RESET or `SCACHE_SCTM_CTCR_WOT_j[1]` RESET bit. If the counter is chained, the high-order and low-order counters are reset when the RESET bit is written for the low-order counter.

Counters can also be reset as groups through the `SCACHE_SCTM_CTGRST` registers. These registers provide control of the individual counter reset in groups. This allows an application to reset groups of counters in lockstep.

## 5.3.12.2 Timer Functions

Counters 0 and 1 in the SCTM can function as timers. When operating as timers, interrupts and/or debug input events are generated when the value of the counter reaches a designated interval.

### 5.3.12.2.1 Periodic Intervals

The interval for a timer is contained in the `SCACHE_SCTM_TINTVLR_i` register. There is a `SCACHE_SCTM_TINTVLR_i` register for every timer-capable counter in the SCTM. Timers are initialized to 0. When the corresponding `SCACHE_SCTM_CTCNTR_k` increments and matches the values designated in `SCACHE_SCTM_TINTVLR_i`, the timer is considered to be triggered and events configured in `SCACHE_SCTM_CTCR_WT_i` are generated.

Timers can function in one of two mutually exclusive modes:

- Run-once mode: The timer stops after the first interval match and is not re-enabled until the timer is reset to the initial value (0) by setting the `SCACHE_SCTM_CTCR_WT_i[1]` RESET bit to 1.
- Restart mode: The timer automatically resets to the initial value (0) each time the designated interval is reached.

The `SCACHE_SCTM_CTCR_WT_i[10]` RESTART bit is used to configure the timer mode.

### 5.3.12.2.2 Event Generation

Timers can generate interrupts and debug events. Interrupts are routed from the module boundary to the INTC in the subsystem. Debug events are routed as triggers to debug logic within the subsystem.

The generation of the interrupts is controlled by the `SCACHE_SCTM_CTCR_WT_i[8]` INT bit. The generation of debug events is controlled by the `SCACHE_SCTM_CTCR_WT_i[9]` DBG bit. The INT and DBG bits can be set simultaneously and both signals are generated on interval match.

If neither INT nor DBG is set, the timer function is disabled and the counter functions as a regular counter.

## 5.3.13 Local Interconnect Network

The local interconnect network is the DSP subsystem internal logic that allows internal communication between the modules of the subsystem (for example, the DSP megamodule can communicate with the eDMA or the WUGEN). Communication with the rest of the system is through the MMU as master port (accesses from the DSP subsystem to the L3 interconnect). The MMU itself is configured from the device MPU through a 32-bit DSPSS slave port on the L4 interconnect.

For information about global memory mapping of the DSP subsystem (DSP CPU view or MPU view through the L3 interconnect), see [Section 2.2, L3 Memory Space Mapping](#) in [Chapter 2, Memory Mapping](#).

#### 5.3.13.1 Endianness

The DSP subsystem local interconnect network does not support the big-endian convention or any type of endianness conversion. Only little endian is supported by the local interconnect network.

#### 5.3.14 Error Reporting

Several mechanisms are available in the DSP subsystem to report errors at different levels.

The INTC of the DSP megamodule allows reporting of dropped interrupts, through the INTERR signal.

L3 out-of-band errors are reported through the external L3 interrupt signal. For details about interrupt mapping, see [Table 5-6](#). For information about L3 interconnect error reporting, see [Section 13.2, L3 Interconnect](#) in [Chapter 13, Interconnect](#).

The eDMA has its own error-reporting mechanism. Error-status registers and error interrupts inform the user of problems during internal operation (data error, bus activity error, etc.) of the DSP subsystem.

For information about error management and the register set that allows error tracing, see [Section 5.4.7, Error Identification Process](#).

## 5.4 DSP Subsystem Programming Guide

### 5.4.1 DSP Boot

The boot-time configuration register is [SYSC\\_BOOTADDR](#). This read-only register is accessible only by the DSP CPU, and its value is determined when the DSP is released from reset, using the [CONTROL.CONTROL\\_DSP\\_BOOTADDR](#) register of the SCM (for more information, see [Section 18.4.12.1, DSP Boot Register](#), in [Chapter 18, Control Module](#)). A change to this register is not seen (not sampled) by the DSP subsystem until the next reset.

The DSP boots in two ways:

- Boot under MPU control, described in [Section 5.4.1.2.1, Boot Under MPU Control](#)
- Autonomous boot, described in [Section 5.4.1.2.2, Autonomous Boot](#)

A boot under MPU control is typically used after the cold reset of the device as a first-time configuration of the DSP subsystem. Subsequent boots of the DSP, resulting from a wake-up transition from OFF state, for example, use the autonomous boot.

#### 5.4.1.1 DSP Boot Configuration

When the DSP subsystem is released from reset, the first fetch address of the C64x equals the address defined in the [CONTROL.CONTROL\\_DSP\\_BOOTADDR\[31:10\] DSP\\_BOOT\\_LOAD\\_ADDR](#) bit field.

This address can be aligned on any 1-KB boundary, in ROM, DSP local RAM, or on-chip memory (OCM-RAM), or directly in external memory (for example, SDRAM through the SDRC).

#### 5.4.1.2 Example of DSP Boot

##### 5.4.1.2.1 Boot Under MPU Control

Before waking up the DSP subsystem, the MPU performs the following sequence:

- Step 1. The MPU prepares a translation table hierarchy (TTH) in SDRAM at address <TTH Physical Address>. This TTH must contain at least an address translation for the DSP MMU physical address range.

---

**NOTE:** The DSP CPU does not require an address translation for the TTH, because the TTH is under MPU control only. The DSP CPU is responsible only for saving and restoring an DSP MMU context that has been programmed by the MPU.

---

- Step 2. The MPU writes a bootstrap sequence in SDRAM at address <bootloader physical address>. This sequence is executable by the DSP CPU and contains only relative address references so that it is relocatable without code modification. This sequence must do at least the following:
  - (a) Set the size of the bootstrap code.
  - (b) Program the DSP MMU.

---

**NOTE:** For more information on the MMU, see [Chapter 20, Memory Management Units](#).

---

- Step 3. Program the DSP MMU.
- Step 4. The MPU can lock some other TLB entries, define some power-management MMU settings, and/or enable some interrupts.
- Step 5. The MPU correctly programs the associated L3 firewall, ensuring that the DSP CPU has read access to the memory area containing the DSP bootstrap sequence.
- Step 6. The MPU programs the associated L3 firewall, ensuring that the DSP CPU has read and write access to the configuration registers of the MMU.
- Step 7. The MPU writes <bootloader physical address> to the [CONTROL.CONTROL\\_DSP\\_BOOTADDR\[31:10\] DSP\\_BOOT\\_LOAD\\_ADDR](#) bit field.

---

**NOTE:** For a detailed description of the system boot register, see [Section 18.4.12.1, DSP Boot Register](#) in [Chapter 18, Control Module](#).

---

Step 8. The MPU configures the DSP subsystem clock rate and DSP subsystem-related power-management settings in the PRCM module.

---

**NOTE:** Following Step 1 through Step 8, the DSP boot sequence is identical to the autonomous boot sequence. For information about the DSP boot sequence, see [Section 5.4.1, DSP Boot](#).

---

After initialization completes, the MPU allows the DSP to boot:

1. The MPU releases the DSP from OFF state by programming the PRCM module.
2. The MPU sets the clocks back to the DSP subsystem.
3. The MPU releases the DSP from reset.

#### 5.4.1.2.2 Autonomous Boot

On an OFF-to-ACTIVE transition (under MPU control or on interrupt wakeup), the DSP subsystem is released from reset.

After hardware configuration of values for DSP megamodule generic parameters, the DSP starts fetching from address 0x0000 0000 in ROM. The DSP subsystem must follow the (nonexhaustive) boot process:

1. Load the bootstrap code:
  - (a) Read the [SYSC\\_BOOTADDR\[31:10\]](#) BOOTLOADADDR bit field.
  - (b) Read the number of bootstrap words (<NbOfWords>) to transfer in the first word at the address pointed to by BOOTLOADADDR.
  - (c) Transfer as many words as defined in <NbOfWords>.
2. Execute the bootstrap code.

---

**NOTE:** This prepares the MMU for address translation of external accesses. In the case of a boot upon interrupt wakeup, the MMU is restored to its exact context before the DSP is shut off, if the context was saved correctly.

Only from this point can the DSP subsystem work with virtual addresses.

---

### 5.4.2 Cache Management

The DSP subsystem has a 2-level cache-based architecture:

- L1 cache (L1 shared cache) consists of a 32-KB memory space.
- L2 memory/cache consists of a 128-KB memory space shared by program and data space. L2 memory can be configured as mapped memory, cache, or a combination of the two.

The virtual address space is split into contiguous chunks to configure which parts of the memory are cacheable and which are not cacheable.

#### 5.4.2.1 Cacheability Settings

This section describes the configuration of cacheability.

The address space of the DSP subsystem is split into contiguous regions of 16MB each. Each region has a cacheable attribute that defines whether a reference to a location belonging to the associated memory region must be sent directly to the memory (with exact size and occurrence as requested by the CPU) or must induce a cache line refill and potentially an eviction of another cache line.

The shared cache contains registers that control whether certain ranges of memory are cacheable and whether one or more requestors is allowed access to these ranges.

## 5.4.2.2 Coherence Maintenance

### 5.4.2.2.1 Memory-Mapped L1 or L2 Coherence

Coherence is maintained by hardware between L1 cache content and the L2 memory-mapped memory region.

An L2 reference from the DSP CPU updating an L1 cache location is automatically made visible to the DMA and any master processor on the device with access to the memory-mapped L2 of the DSP megamodule through the DSP subsystem slave port.

An L2 reference from the DMA and any other master processor on the device with access to the memory-mapped L2 of the DSP megamodule through the DSP subsystem slave port is automatically made visible to the DSP CPU through the L1 cache, if it is holding the associated cache line.

### 5.4.2.2.2 Device Memory Coherence

Coherence is not maintained by hardware between the L2 cache (and L1 cache) and device memories (on-chip memories external to the DSP subsystem and off-chip memories connected to the SDRAM controller and/or general-purpose memory controller [GPMC]). Coherence in this case must be handled by software. The DSP megamodule offers two sets of registers for user-initiated coherence maintenance between DSP local memories and device memories.

Software coherence maintenance must be synchronized in the system (for example, through message passing; for information, see [Chapter 19, Mailbox](#)). In the producer/consumer model, the producer sends a completion message to the consumer only after the write is complete in end memory. If the producer has a cache-based architecture, the producer must initiate a write-back and track for the completion of the write-back sequence in end memory. When the consumer receives the message, if the consumer has a cache-based architecture, updates by the producer must be seen (not a local nonupdated copy). For a description of how the invalidate sequence occurs in the DSP subsystem, see [Section 5.4.2.2.3, Global Cache Management](#).

Two types of cache coherence management are possible:

- Global cache coherence allows the DSP CPU to ensure coherence of the entire cache at once. See [Section 5.4.2.2.3, Global Cache Management](#).
- Block cache coherence allows the DSP CPU to ensure coherence of a contiguous region of the virtual address map, restricted in size to only what is needed.

Each management type provides three sets of actions:

- Invalidate ensures that all required lines are made invalid in the cache. After that operation, any update (before invalidate operation) in end memory by an alternate processor/DMA is seen by the DSP CPU, thus forcing a cache line refill.
- Write-back ensures that all required cache lines modified by the DSP CPU (also called dirty lines) are written back to end memory so that any local update by the DSP CPU is made visible by an alternate processor/DMA. This applies to L1 and L2 caches.
- Write-back and invalidate ensure that all required cache lines modified by the DSP CPU are written back to end memory so that any local update by the DSP CPU is made visible by an alternate processor/DMA; they also ensure that all required lines are made invalid in the cache. After that operation, any update in end memory by an alternate processor/DMA is seen by the DSP CPU, thus forcing a cache line refill. This applies to L1 and L2 caches.

### 5.4.2.2.3 Global Cache Management

This section describes how to invalidate and write-back cache memory.

Maintenance is provided using the MMU. In addition, the L1 and L2 caches have independent start and end regions that are not limited by the size of the MMU entries.

Either MMU maintenance or cache maintenance can be used. However, only one maintenance operation at a time occurs. Direct cache maintenance also provides interrupts when complete.

Unlike MMU maintenance, direct cache maintenance locks only the lines already allocated in the cache, and not as needed during allocation.

#### 5.4.2.2.3.1 Direct Maintenance of Caches

Shared cache allows basic maintenance operations, which are performed through a dedicated interface:

1. Preload
2. Lock
3. Clean
4. Invalidate

Maintenance of the cache is performed between the start and end addresses. This allows for direct control of the memory regions. All maintenance operations occur in the background and can generate an interrupt when they complete.

Cache maintenance is controlled by the following registers:

- [SCACHE\\_MTSTART](#)
- [SCACHE\\_MTEND](#)
- [SCACHE\\_INT](#)
- [SCACHE\\_MAINT](#)

Example of global maintenance operation:

1. Configure the start address for cache maintenance by writing the [SCACHE\\_MTSTART](#) register.
2. Configure the end address for cache maintenance by writing the [SCACHE\\_MTEND](#) register.
3. (optional) Activate interrupt generation by writing 0x1 to the [SCACHE\\_MAINT\[5\]](#) INTERRUPT bit.
4. Select the maintenance type by writing to the [SCACHE\\_MAINT\[4:0\]](#) bit field (according to the selected maintenance).
5. Wait for the [SCACHE\\_INT\[2\]](#) MAINT bit to be set to 0 (maintenance is done).

---

**NOTE:** Hardware ensures that the maintenance operations are done first in L1, and then in L2.

---

#### 5.4.2.2.3.2 MMU Maintenance

The MMU provides maintenance control for the CPU and MPORT. This can be done by setting the MMU small pages, or alternatively by setting the region for maintenance.

This is done to ensure that the caches can be maintained automatically across cache boundaries. For all maintenance operations, the L1 caches are updated before the L2 caches. This ensures that evictions from L1 are complete before any L2 maintenance.

If there are cache misses during maintenance clean/invalidate, they are considered noncacheable misses until the operation completes. However, hits function normally.

Individual caches can also be maintained separately using start and end addresses instead of pages. However, using MMU page maintenance has the benefit that the serialization is automatic. Also, the preload/lock feature is automatic during cache misses if the MMU maintenance is performed.

The basic control functions for maintenance are:

1. Preload
2. Lock
3. Clean (write out dirty lines, but do not invalidate directly)
4. Invalidate

These functions can be used in combination as described in Table 5-7. Either an interrupt or polling of the small page maintenance register indicates whether the maintenance operation is complete.

Only one maintenance operation at a time can be performed, including whether the processor directly accesses the cache maintenance registers. If the user writes a new maintenance operation before the first one completes, the configuration interface stalls.

Table 5-7 shows the combinations and results of setting multiple maintenance functions.

**Table 5-7. Maintenance Combinations**

Action Combinations	Preload	Lock	Unlock	Clean	Invalidate
Preload	1	0	0	0	0
Lock	0	1	0	0	0
Unlock	0	0	1	0	0
Clean dirty lines	0	0	0	1	0
Invalidate lines only	0	0	0	0	1
Clean -> Invalidate	0	0	0	1	1
Preload -> Lock	1	1	0	0	0
Clean -> Lock	0	1	0	1	0
Bus error	1	x	x	1	x
Bus error	1	x	x	x	1

**NOTE:**

1. Illegal maintenance combinations (anything not listed in Table 5-7) generate a bus error (response error) on the configuration interface.
2. When a region is set for locking, the pages currently in the cache and any further misses to that region are locked.
3. Locked pages can still be cleaned or invalidated.
4. If all ways of the cache are locked and an allocation cannot occur, no bus error is generated. If a cache is missed when all ways are locked, the data is returned to the CPU, but the line is not allocated in the cache.
5. Queries from MPORT clean and invalidate lines even if they are locked.
6. Once page maintenance begins, the user cannot update the page again until the maintenance is complete.

#### 5.4.2.2.3.2.1 Global Flush

Global flush is controlled by the [SCACHE\\_MMU\\_MAINT](#) and [SCACHE\\_MMU\\_MAINTST](#) registers.

Example of global flush:

1. Write 1 to the [SCACHE\\_MMU\\_MAINT](#)[10] G\_FLUSH bit.
2. Wait for the [SCACHE\\_MMU\\_MAINTST](#) [0] STATUS bit to be set to 0 (maintenance is done).

**NOTE:** Hardware ensures that the maintenance operations are done first in L1, and then in L2.

#### 5.4.2.2.3.2.2 Maintenance of Caches Through MMU

Global maintenance is controlled by the [SCACHE\\_MMU\\_MAINT](#) and [SCACHE\\_MMU\\_MAINTST](#) registers.

Example of global maintenance:

1. Start cache maintenance by writing 1 to the following registers:
  - (a) [SCACHE\\_MMU\\_MAINT](#)[7] L1\_CACHE1 bit to invalidate L1 cache 1
  - (b) [SCACHE\\_MMU\\_MAINT](#)[8] L1\_CACHE2 bit to invalidate L1 cache 2
  - (c) [SCACHE\\_MMU\\_MAINT](#)[9] L2\_CACHE bit to invalidate L2 cache
2. Wait for the [SCACHE\\_INT](#)[2] MAINT bit to be set to 0 (maintenance is done).

---

**NOTE:** Hardware ensures that the maintenance operations are done first in L1, and then in L2.

---

#### 5.4.2.3.2.3 Maintenance of MMU Pages

MMU page maintenance is controlled by the following registers:

- [SCACHE\\_MMU\\_MAINT](#)
- [SCACHE\\_MMU\\_MTSTART](#)
- [SCACHE\\_MMU\\_MTEND](#)
- [SCACHE\\_MMU\\_MAINTST](#)

Example of invalidate:

1. Configure the start address for the cache maintenance by writing the [SCACHE\\_MMU\\_MTSTART](#) register.
2. Configure the end address for the cache maintenance by writing the [SCACHE\\_MMU\\_MTEND](#) register.
3. (optional) Activate interrupt by setting the [SCACHE\\_MMU\\_MAINT](#)[6:5] bit field to 1.
4. Select the maintenance type by setting the [SCACHE\\_MMU\\_MAINT](#)[4:0] bit field.
5. Wait for the [SCACHE\\_MMU\\_MAINTST](#)[0] STATUS bit to be set to 0 (maintenance is done).

### 5.4.3 DMA Management

#### 5.4.3.1 Transfers From/To Device Memories/Peripherals (eDMA)

The eDMA optimizes transfers from/to the DSP megamodule (memory-mapped) memories to/from device on-chip and off-chip memories.

The eDMA can perform transfers from DSP internal memories to DSP internal memories. In this case, use the eDMA with the locked feature.

The eDMA can perform transfers between device memories/peripherals, but it is not designed for that purpose. The sDMA is recommended in that case. For more information, see , *sDMA Basic Programming Model* in [Chapter 16, Direct Memory Access Controllers](#).

#### 5.4.3.2 Programming an eDMA Transfer

Programming a complete eDMA transfer requires the following steps:

- Step 1. Define the logical channel(s).
- Step 2. Prioritize the defined transfer (with respect to other defined transfers).
- Step 3. Start the transfer.
- Step 4. Review the progression and completion of the transfer.

#### 5.4.3.3 Defining a Logical Channel

##### 5.4.3.3.1 Single Logical Channel Definition

A complete eDMA transfer can be defined by one or several chained and/or linked logical channels.

Up to 128 independent contexts, each fully defining a logical channel, can be defined. These 128 contexts correspond to the 128 PaRAM entries available in the DSP subsystem. For more information about these PaRAM entries, see [Section 5.3.3.1.3, DMA/QDMA Channel Mapping and PaRAM Entry](#), and the corresponding [Figure 5-9](#).

Logical channel definition relies on the following:

- Base addresses:
  - [PARAM\[LCH#\].SRCi](#): 32-bit source address
  - [PARAM\[LCH#\].DSTi](#): 32-bit destination address

- Transfer sizes:

Transfer size is common to source and destination. A transfer can be constituted on a 3D array; C is an array of CCNT arrays, each composed of BCNT arrays, each composed of ACNT bytes:

- PARAM[LCH#].ACNT: Number of bytes in the A array (from 0 to 65,535)
- PARAM[LCH#].BCNT: Number of A arrays in the B array (from 0 to 65,535)
- PARAM[LCH#].CCNT: Number of B arrays in the C array (from 0 to 65,535)

---

**NOTE:** Setting one of the ACNT, BCNT, or CCNT arrays to 0x0 prevents a transfer from being submitted to one of the physical channels (assuming that the compatibility mode is not set; see Kelvin DMA compatibility mode).

---

- PARAM[LCH#].BCNTRLD: BCNT reload value when BCNT reaches 0 (from 0 to 65,535)

---

**NOTE:** When programming CCNT>1, it is recommended to program PARAM[LCH#].BCNTRLD to be equal to PARAM[LCH#].BCNT.

---

- Indexes between dimensions:

- PARAM[LCH#].SRCBIDX: Index between A arrays at source (from -32,768 to 32,767)
- PARAM[LCH#].SRCIDX: Index between B arrays at source (from -32,768 to 32,767)
- PARAM[LCH#].DSTBIDX: Index between A arrays at destination (from -32,768 to 32,767)
- PARAM[LCH#].DSTCIDX: Index between B arrays at destination (from -32,768 to 32,767)

---

**NOTE:** Programming the logical channel does not automatically start it. See [Section 5.4.3.5.1, Assigning a Logical Channel to a Trigger Event](#).

---

- Addressing modes:

- PARAM[LCH#].OPT[0] SAM: Source addressing mode (0: post-incremented; 1: constant)
- PARAM[LCH#].OPT[1] DAM: Destination addressing mode (0: post-incremented; 1: constant)

---

**NOTE:** Constant addressing mode is supported only from/to the DSP megamodule memories, not from/to device memories and peripherals. This can be replaced by using a post-increment addressing mode and an index equal to 0.

---

**Example:**

```

/* ----- */
/* fills dstArray with cstValue values (w/o constant AM) */
/* ----- */
PARAM[LCH#].SRC = &cstValue;
PARAM[LCH#].DST = &dstArray[0];
PARAM[LCH#].ACNT = sizeof(int);
PARAM[LCH#].BCNT = sizeof(dstArray) / sizeof(int);
PARAM[LCH#].CCNT = 1;
PARAM[LCH#].SRCBIDX = 0;
PARAM[LCH#].DSTBIDX = sizeof(int);
PARAM[LCH#].OPT.SAM = 0;
PARAM[LCH#].OPT.DAM = 0;

```

#### 5.4.3.3.2 Controlling Submission Granularity

The logical channel (when triggered) can split a transfer into several requests submitted to one of the physical channels. The physical channel supports submitted requests of up to two dimensions, meaning that a 3D transfer is always split into (at least) 2D transfers. The user can also program the logical channel so that submitted requests are 1D transfers; for example:

- PARAM[LCH#].SYNCDIM = 0; // submitted transfers are maximum 1D.
- PARAM[LCH#].SYNCDIM = 1; // submitted transfers are maximum 2D.

### 5.4.3.3 Linking to Another Logical Channel

A logical channel can be programmed so that on its completion another context is copied from another logical channel. This is useful because the logical channel is used as a working set during the DMA transfer, meaning that the initial context configuration is lost after the associated transfer completes.

- `PARAM[LCH#].LINK = linkLCH# << 5`

The LINK value is the base address of the linked logical channel context.

When the LINK value is set to `0xFFFF`, no context is loaded for that logical channel:

- `PARAM[LCH#].LINK = -1`

---

**NOTE:** Only the context is copied, and the logical channel is not automatically restarted on link. Restarting a logical channel that just received its new context occurs only when a trigger event associated with that logical channel is detected. See [Section 5.4.3.5.1, Assigning a Logical Channel to a Trigger Event](#).

---

### 5.4.3.3.4 Chaining Logical Channel

A logical channel can be programmed so that on its total or partial completion, another logical channel is started. This is useful for defining a series of transfers with different contexts as a complete DMA transfer. The main advantage is that the overhead to program all the chained transfers is shared among all channels.

- Partial completion chaining

After the submitted section (see [Section 5.4.3.3.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If partial completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 5.4.3.5.1, Assigning a Logical Channel to a Trigger Event](#).

For example, to chain a logical channel LCHi to LCHj so that LCHj is automatically started after each LCHi submission to a physical channel completes:

- `PARAM[LCHi].OPT.TCC = trigEvtx; // trigEvtx: Trigger event number`
- `PARAM[LCHi].OPT.ITCCHEN = 1`
- `DCHMAP[trigEvtx] = LCHj`

- Total completion chaining

After all submitted parts of a logical channel are complete, the programmable completion code is returned. If total completion chaining is enabled in the context of the logical channel, this completion code defines which trigger event is set. The logical channel associated with that trigger event is automatically submitted. See [Section 5.4.3.5.1, Assigning a Logical Channel to a Trigger Event](#).

For example, to chain a logical channel LCHi to LCHj so that LCHj is automatically started after LCHi completes:

- `PARAM[LCHi].OPT.TCC = trigEvtx; // trigEvtx: Trigger event number`
- `PARAM[LCHi].OPT.TCCHEN = 1`
- `DCHMAP[trigEvtx] = LCHj`

## 5.4.3.4 Prioritizing Defined Transfers

### 5.4.3.4.1 Mapping Between DMA/QDMA Events and Event Queues

The assignment of 64 DMA and 8 QDMA channels to two event queues of the channel controller is achieved by configuring the DMA queue number register (`TPCC_DMAQNUM_n`, where  $n = 0$  to 7) and the QDMA queue number register (`TPCC_QDMAQNUM`). When an event is selected for submission, it is queued in the user-defined event queue. This typically defines a 2-level priority preemption scheme, because queues are usually mapped to different transfer controllers.

#### 5.4.3.4.2 Mapping a Queue to a Transfer Controller

Events at the head of an event queue define which logical channel (PaRam entry) is selected for submission to the associated physical channel (transfer controller). The association between an event queue and a physical channel can be defined in the `TPCC_QUETCMAP` register. By default, TPTC0 is associated with event queue 0, and TPTC1 is associated with event queue 1. This mapping is a static decision; it does not change during DMA operation.

---

**NOTE:** TPTC0 and TPTC1 are not symmetrical; their numbers are simply inverted, compared to the Davinci device. To improve compatibility with Davinci devices, invert the mapping of the event queue to the transfer controller, as shown in the following:

`QUETCMAP = (QUETCMAP & ~0xFF) | 0x10;`

Typically, this is used to allow submission-time preemption so that by example:

- Event queue 0 is used for background, potentially long, not latency-sensitive, noncritical DMA transfers.
  - Event queue 1 is used for short, latency-sensitive, or critical (for example, hardware-synchronized) DMA transfers.
- 

#### 5.4.3.4.3 Handling Priority

In DSP subsystem local interconnect arbitration, the priority of individual bus requests for a DMA transfer over other DMA- or CPU-initiated bus requests is defined by the event queue to which the event associated with the transfer is submitted. This can be configured per event queue in the `TPCC_QUEPRI[2:0] PRIQ0` and `TPCC_QUEPRI[6:4] PRIQ1` bit fields. By default, event queues 0 and 1 have the same priority (the highest possible priority is 0x0).

Typically, this is used to allow transfer-time preemption so that, for example, bus requests associated with event queue 1 are served before event queue 0 or CPU requests.

Example:

- `// DMA#0->0x7 (lowest), DMA#1->0x0 (highest), CPU->0x4 (mid)`
- `QUEPRI = (QUEPRI & ~0xFF) | 0x07;`
- `MDMAARBE = (QUEPRI & ~(0xF16)) | 0x4 16;`

#### 5.4.3.4.4 Aged Priority

To prevent DMA requests from being stalled for a long time, the DSP subsystem implements an aged priority scheme (also referred to as an inversion priority scheme) on the DMA ports to change the priority defined in the `TPCC_QUEPRI` register. This is done by regularly decreasing the priority level (increasing the priority in arbitration) of a stalled request. The interval between two consecutive updates of the priority level is defined in the `SYSC_EDMA` register. By default, the aged priority scheme is disabled (`SYSC_EDMA = 0x0`), and the arbitration priority is dictated by values programmed in `TPCC_QUEPRI`.

#### 5.4.3.5 Starting the Transfer

Before starting the transfer, a trigger event must be associated with the logical channel. Three modes trigger a DMA transfer:

- Manual (software-synchronized transfers)
- Hardware (hardware-synchronized transfers)
- Automatic (automatic on-submission transfer start)

##### 5.4.3.5.1 Assigning a Logical Channel to a Trigger Event

The 64 DMA channels and the 8 QDMA channels can be flexibly mapped to any of the 128 available PaRAM entries (see [Figure 5-9](#)).

Any of the 64 DMA channels can be mapped to any of the 128 PaRAM entries through the DMA channel-mapping registers `TPCC_DCHMAPN_i` (where  $i = 0$  to 63).

Any of the 8 QDMA channels can be mapped to any of the 128 PaRAM entries through the QDMA channel-mapping registers `TPCC_QCHMAPN_j` (where  $j = 0$  to 7).

#### 5.4.3.5.2 Manual Trigger (Software-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 63) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers (`TPCC_DCHMAPN_i`, where  $i = 0$  to 63). Then, the user can manually start the transfer (one logical channel or a chained list of logical channels) by writing 1 to the bit in the `TPCC_ESR` or `TPCC_ESRH` register associated with the trigger event of the logical channel (or the first logical channel in the chained list).

---

**NOTE:** The event does not have to be enabled in the `TPCC_EER` register to be manually triggered.

---

Example:

```
/* ----- */
/* To manually start defined logical channel #0x3, uses event #20 */
/* ----- */
DCHMAP[20] = (DCHMAP[20] & ~(0x1FF<<5)) | 0x3<<5; ESR = 1 << 20;
```

#### 5.4.3.5.3 Hardware Trigger (Hardware-Synchronized Transfers)

When a logical channel is defined and prioritized, the user can assign the logical channel (or the first in the chained list) to a trigger event (from 0 to 19) by writing the number of the logical channel (PaRAMEntry #) to one of the DMA channel-mapping registers (`TPCC_DCHMAPN_i`, where  $i = 0$  to 19). The user can allow this logical channel to be triggered by an associated hardware DMA request by writing 1 in the associated bit of the EER register. The mapping of a hardware DMA request to DMA events is fixed. The mapping of DMA requests to device peripheral sources is listed in [Table 5-3](#).

Example:

```
/* ----- */
/* Associate defined logical channel #0x5 to UART3_DMA_TX */
/* UART3_DMA_TX is DMA request #10 and associated to evt #10 */
/* ----- */
DCHMAP[10] = (DCHMAP[10] & ~(0x1FF<<5)) | 0x5<<5;
```

#### 5.4.3.5.4 Automatic Trigger (QDMA)

The user can specify a trigger word from any of the eight 32-bit words of the logical channel context (PaRAM entry) for QDMA. Writing to the trigger word triggers the channel controller of QDMA to issue a transfer request. The trigger word field of the QDMA channel mapping register `TPCC_QCHMAPN_j` (where  $j = 0$  to 7) defines the trigger word for a particular QDMA channel, as shown in [Figure 5-9](#).

This flexibility enables the CPU to selectively modify only the PaRAM entry that requires modification and thereby trigger the transfer. For example, after a transfer, if only the count must change, QCHMAP can be configured so that count is the trigger word, and a write to it automatically triggers the transfer.

Example:

```
/* ----- */
/* Associate defined logical channel #0x5 to QDMA #1 */
/* ----- */
QCHMAP[1] = (QCHMAP[1] & ~(0x1FF<<5)) | 0x5<<5;
/* ----- */
/* Define DST parameter (0x3) to be trigger word of LCH */
/* ----- */
QCHMAP[1] = (QCHMAP[1] & ~(0x7<<2)) | 0x3<<2;
```

#### 5.4.3.5.5 Direct Configuration to Transfer Channel (Not Recommended)

The registers of the physical channels are memory-mapped primarily to enable, clear, and read status for error interrupts generated by the physical channel. For more information, see [Section 5.4.7, Error Identification Process](#).

It is possible to write directly to other control registers of the physical channels and to issue a transfer; however, this is not recommended and therefore is not described here.

**CAUTION**

This can work safely only if the DMA controller is not used.

#### 5.4.3.5.6 DMA Completion Mode

The DSP eDMA defines when a DMA transfer is complete:

- Early completion: All associated transfers were submitted to the physical channel. Early completion does not ensure that the transfer is complete in end memory.
  - PARAM[LCHi].OPT.TCCMODE = 1
- True completion: All associated transfers were submitted to the physical channel and all are complete from the physical channel standpoint. True completion ensures that the transfer is complete in end memory.
  - SYSC\_VBUSM2OCP.DMATRUECOMPEN = 1; // is statically set.
  - PARAM[LCHi].OPT.TCCMODE = 0

---

**NOTE:** TCCMODE = 0 does not ensure that the transfer is complete in end memory if DMATRUECOMPEN = 0.

---

By default, DMATRUECOMPEN = 0. This is recommended to statically set DMATRUECOMPEN.

True completion is typically used when the DSP DMA is the producer of a buffer shared with another master processor or a DMA (consumer). A completion message is sent to the consumer only after the DMA transfer is complete.

Completion mode affects the timing for the following actions:

- IPR/IPRH bit update (for polling scheme)
- Interrupt generation (for interrupt scheme)
- CER/CERH bit update (for chaining)

#### 5.4.3.5.7 Partial Versus Total Completion

DMA can be programmed so that the IPR bit update and interrupt generation occur:

- After each submission to the physical channel is complete
- After the last submission to the physical channel is complete

##### Partial completion interrupt

After the submitted section (see [Section 5.4.3.3.2, Controlling Submission Granularity](#)) of a logical channel is complete, a programmable completion code is returned. If a partial completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after each LCHi submission to a physical channel is complete:

- PARAM[LCHi].OPT.TCC = intEvtX; // intEvtX: IPR bit to be updated
- PARAM[LCHi].OPT.ITCINTEN = 1

##### Total completion interrupt

After all submitted parts of a logical channel are complete, a programmable completion code is returned. If a total completion interrupt is enabled in the context of the logical channel, this completion code defines which IPR bit is set.

For example, to allow IPR to be updated (and possibly an interrupt to be generated) after all LCHi submissions to a physical channel are complete:

- PARAM[LCHi].OPT.TCC = intEvtx; // intEvtx: IPR bit to be updated
- PARAM[LCHi].OPT.TCINTEN = 1
  - By polling
  - By interrupt

#### 5.4.3.5.8 Tracking DMA Completion

There are two ways to track DMA completion:

- Polling the completion register when the estimated completion time has elapsed
- Enabling completion interrupts

##### Polling example (total completion)

- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does not contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 0<<myTCC
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // poll IPR bit
- while( !(IPR & (1<<myTCC)) ); // polls for completion

##### Interrupt example (total completion)

- disable\_interrupts()
- PARAM[myLCH].OPT.TCINTEN = 1; // total interrupt completion bit update
- PARAM[myLCH].OPT.ITCINTEN = 0; // no partial interrupt completion bit update
- PARAM[myLCH].OPT.TCC = myTCC
- // myTCC does contribute to interrupt generation (polling mode)
- IER = (IER & ~(1<<myTCC)) | 1<<myTCC
- INTMUX[0] = (INTMUX[0] & ~(0x7F)) | 0x1D; // map CPU it #4
- CPU.IER = (CPU.IER & (1<<4)) | 1<<4; // unmask CPU it #4
- enable\_interrupts()
- // start transfer
- DCHMAP[myEvt] = (DCHMAP[myEvt] & ~(0x1FF<<5)) | myLCH<<5
- ESR = 1 << myEvt
- // do something useful (that does not depend on DMA completion)
- // this code is interrupted when DMA completes

#### 5.4.3.5.9 DMA Interrupt Service Routine

The channel controller does not generate a new interrupt signal for new pending interrupts if the user did not clear previous pending interrupts. There are two options for constructing an interrupt service routine (ISR) for DMA. The first option is to poll all the bits during execution of the ISR and clear all enabled bits in an interrupt-pending register by writing to the interrupt-pending clear (ICR/ICRH) register before exiting any ISR. The pseudo-code for this option is:

- Step 1. Enter ISR.
- Step 2. Read [TPCC\\_IPR](#).
- Step 3. For the condition set in [TPCC\\_IPR](#):

- (a) Perform operation as needed.
  - (b) Clear bit for serviced INT.
- Step 4. Read IPR:
- (a) If `TPCC_IPR` = 0, exit ISR.
  - (b) If `TPCC_IPR` = 1, return to Step 3.

The second option is to service the ISR, and then before exiting the ISR, write to the EVAL bit of the IEVAL register. This forces the eDMA channel controller to generate a new interrupt signal, if there are interrupts in the interrupt-pending register (IPR/IPRH). The pseudo-code for this ISR option is:

- Step 1. Enter ISR.
- Step 2. Read `TPCC_IPR`.
- Step 3. For the condition set in `TPCC_IPR`:
  - (a) Perform operation as needed.
  - (b) Clear bit for serviced INT.
- Step 4. Read IPR:
  - (a) If `TPCC_IPR` = 0, exit ISR.
  - (b) If `TPCC_IPR` = 1, set the `TPCC_IEVAL.EVAL` bit to force triggering a new interrupt.

#### 5.4.3.5.10 Benchmarking

The DMA channel controller monitors the number of event entries in an event queue to determine whether they exceed the user-programmed threshold. The queue threshold for each event queue can be programmed in the `TPCC_QWMTHRA` and `TPCC_QWMTHRB` registers. When the number of event entries in an event queue exceeds the user-programmed threshold, a queue threshold error occurs. This error is captured in the THRXCDBit field of event-queue status register `TPCC_QSTATN_i` (where  $i = 0$  or  $1$ ) and in the `TPCC_CCERR.QTHRXCDBn` bit field.

#### 5.4.3.5.11 Kelvin DMA Compatibility Mode

Any channel can be configured to keep compatibility with Kelvin DMA settings. To do this, the user must set the `TPCC_OPT_m[19].WIMODE` bit. It is recommended to always clear this bit, except when reusing existing Kelvin code.

- `PARAM[LCH#].OPT.WIMODE = 0`

---

**NOTE:** If reusing existing Kelvin code, see the *eDMA Migration Guide for DM420*.

---

### 5.4.4 Interrupt Management

#### 5.4.4.1 Interrupt Flow in DSP Subsystem

The DSP megamodule INTC detects, combines, and routes up to 128 system events (internal and external) to the 12 DSP CPU interrupt lines. For more information about interrupt mapping of the DSP subsystem (internal and external interrupts), see [Table 5-6](#).

In addition to performing handshaking for chip-level wake-up sequencing for waking from static power-down, the WUGEN of the DSP megamodule internally routes the interrupt request to the IC module. This occurs because the WUGEN is the only DSP megamodule module in the CORE power domain to enable the powered-off DSP subsystem to be awakened after the DSP receives an interrupt from any device peripheral.

[Figure 5-23](#) shows the interrupt flow of the DSP subsystem with the main WUGEN and IC registers used for event generation.

Figure 5-23. DSP Subsystem Interrupt Flow

dsps-040

---

**NOTE:** The CSR/TCR, IER, IFR, and ICR registers belong to the DSP CPU block (C64x+). For more information, see the C64x+ documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).

---

#### 5.4.4.2 Event Combined Programming Sequence

In addition to generating a combined interrupt based on programmable event combinations, the event combiner provides a masked view of the event flag registers. By reading the masked event flag registers (SYS\_INTC\_MEVTFLAG<sub>i</sub>, where  $i = 0$  to 3), the DSP CPU sees only the event flags pertaining to the corresponding combined event (EVT<sub>x</sub>, where  $x = 0$  to 3).

When servicing a combined interrupt, perform the following steps:

- Step 1. Read the SYS\_INTC\_MEVTFLAG<sub>i</sub> register corresponding to the combined event EVT<sub>x</sub>.
- Step 2. Check the pending events.
- Step 3. Write the value of the SYS\_INTC\_MEVTFLAG<sub>i</sub> register into the SYS\_INTC\_EVTCLR<sub>i</sub> register (where  $i = 0$  to 3).
- Step 4. Service the received interrupts.
- Step 5. Repeat Step 1 through Step 4 until SYS\_INTC\_MEVTFLAG<sub>i</sub> = 0x0.

This clears only those events combined on EVT<sub>x</sub>. Events masked in the SYS\_INTC\_EVTMASK<sub>i</sub> register (where  $i = 0$  to 3) do not need to be cleared if they are set in the SYS\_INTC\_EVTFLAG<sub>i</sub> register (where  $i = 0$  to 3) (they can generate an exception or are used as event outputs).

Before returning, the DSP CPU must repeat Step 1 through Step 4 until no pending events are found. This ensures that events received during the ISR are captured. If an event EVT<sub>x</sub> is received at the same time that its flag is being cleared in the SYS\_INTC\_EVTCLR<sub>i</sub> register, it does not clear. Repeating Step 1 through Step 4 ensures that no events are missed.

#### 5.4.4.3 Event <-> Interrupt Mapping Programming Sequence

The DSP INTC allows programming independently which of the 128 input events is mapped to each DSP CPU interrupt; this is done by writing the event number in the bit field that corresponds to the CPU interrupt in the SYS\_INTC\_INTMUX<sub>j</sub> register (where  $j = 1$  to 3).

Example:

```
/* ----- */
/* evtTable has the 12 evt <-> CPU interrupt mapping */
/* ----- */
evtTable[0] = 55; // Mailbox event highest priority
evtTable[1] = 61;
// McBSP1TX event[...]
evtTable[11] = 29;
// EDMA3 gbl completion event lowest priority
for(I=0; i<12; I++){
// for each CPU maseable interrupt{
INTMUX(I >> 2 + 1) |= (evtTable[i] & 0x7F) << ((I & 0x3) << 3);}
}
```

#### 5.4.4.4 Interrupt Exception Programming Sequence

The INTC can generate a system event (INTERR) that is internally routed to system event input EVT96. This event is generated when a DSP CPU interrupt is dropped (a DSP CPU interrupt is received while the interrupt flag is already set in the DSP CPU).

This can inform the user of possible problems in the software code, such as whether interrupts were disabled for an extended period of time, or whether pipelined (noninterruptible) code sections were too long.

---

**NOTE:** Because the interrupt drop detection logic is in the CPU, only interrupts sourced from a single system event can be detected. The dropping of individual combined events is not possible, although dropping the output of an event combiner is possible. Only the first dropped interrupt detected is reported by the INTERR event.

---

The [SYS\\_INTC\\_INTXSTAT](#) register holds the ID of the CPU interrupt and the system event number of the dropped event. By setting the [SYS\\_INTC\\_INTXCLR\[0\]](#) CLEAR bit to 1, the software user resets the [SYS\\_INTC\\_INTXSTAT](#) register to 0.

When servicing the interrupt exception, the CPU performs three steps:

1. Reads the [SYS\\_INTC\\_INTXSTAT](#) register
2. Checks the error condition
3. Clears the error through the [SYS\\_INTC\\_INTXCLR](#) register

The dropped events that generate the INTERR event (EVT96) can be qualified by a mask register. CPU interrupts that are to be ignored by the drop detection hardware can be masked in the [SYS\\_INTC\\_INTDMASK](#) register.

#### 5.4.4.5 INTC Basic Programming Model for Power Down of DSP Subsystem

When going to a low-power state not involving DSP subsystem logic power off, there are no special software settings to perform. In particular, the noncombined interrupts can be used without any specific handling for that power transition. To run the procedure for a correct transition to power-down state not involving logic-off, the user must perform the following procedure:

1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts and are unmasked in combined event registers (if combined events are used).
2. Clear the associated bits in the [WUGEN\\_MEVT0](#) and [WUGEN\\_MEVT1](#) registers to unmask wake-up interrupts.

---

**NOTE:** Software must not unmask an event in the WUGEN that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the DSP subsystem exits the power-down state but does not wake up.

---

The user must program the following procedure when transitioning to the (logic) power-off state (OFF state for the device):

- Step 1. Ensure that all wake-up events are correctly mapped to enabled DSP CPU interrupts and are unmasked in combined event registers (if combined events are used).
- Step 2. Clear the correct bits in the [WUGEN\\_MEVT0](#) and [WUGEN\\_MEVT1](#) registers to unmask wake-up interrupts.
- Step 3. Save the necessary context (all except interrupt-related registers).

---

**NOTE:** Step 3 through Step 5 are automatic, but interruptible. If a wake-up interrupt occurs at this stage, the transition to power down is canceled and the next transition restarts from the beginning.

Software tip: A software variable (semaphore) can be set in Step 3, modified in all calls of the wake-up interrupt ISR routine, and checked before executing the IDLE instruction in Step 5. For a complete description of the DSP CPU ISR, see the C64x+ documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).

---

- Step 4. Save the interrupt configuration in the following registers:
  - (a) [SYS\\_INTC\\_INTMUXj](#) (where j = 1 to 3)
  - (b) [SYS\\_INTC\\_EVTMASKi](#) (optional, where i = 0 to 3)
  - (c) [SYS\\_INTC\\_INTDMASK](#) (optional)
  - (d) DSP CPU IER. For a description of the IER, see the C64x+ documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).
- Step 5. Execute the DSP IDLE instruction.

---

**NOTE:** Software must not unmask an event in the WUGEN that is not correctly mapped to an enabled DSP CPU interrupt. If that event is triggered, the DSP subsystem exits the power-down state but does not wake up.

---

#### 5.4.4.6 INTC Basic Programming Model for Power On of DSP Subsystem

Noncombined events can be lost after power on wakeup of the DSP megamodule. To avoid this, one solution is to replay the DSP CPU interrupt after restoring the interrupt selector and event combiner context.

- Programming model at boot time

There is no specific software setting required to use combined/noncombined events during normal operation. However, at boot time, the event can be captured in the event-combiner event flag and not be propagated to the DSP. To do this, the following procedure must be performed:

1. The DSP subsystem logic ensures that interrupts are presented to the DSP megamodule only after:
  - (a) The DSP megamodule module has its clock.
  - (b) The DSP megamodule module is reset correctly.
2. From the time the pre-idle sequence is started to the time when the DSP subsystem context is fully restored and operational after wakeup, it is assumed that only external (from device peripherals) interrupts can occur. Internal interrupts in the DSP megamodule can result only from an application software side effect; the application is stopped when entering the pre-idle sequence and is restarted only after the DSP subsystem context is fully restored and operational. eDMA interrupts are inactive at this stage, because the eDMA module is completely reset after power up, and a software action is required to reactivate the eDMA interrupts.
3. All device peripheral interrupts are level and are kept asserted until software acknowledges the interrupt by writing 1 to the interrupt status register (DSP CPU ISR) bit corresponding to the enabled asserted event(s). The device peripheral must keep an event flag to track missed interrupts. For a complete description of the DSP CPU ISR, see the C64x+ documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).
4. There is no specific requirement to configure or restore interrupt mapping, except having the interrupts globally disabled during the sequence:
  - (a) Set the DSP CPU TSR[0] or CSR[0] GIE bit to 0 to disable all interrupts except the reset interrupt and nonmaskable interrupt (NMI). The GIE bit is the same physical bit in the TSR and CSR. For a complete description of these registers, see the C64x + documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).
  - (b) Remap interrupts by configuring the SYS\_INTC\_INTMUXj registers (where j = 1 to 3).
  - (c) Set the DSP CPU TSR[0] or CSR[0] GIE bit to 1 to enable all DSP CPU interrupts.

The DSP CPU software recognizes which degree of power state the C64x reaches when executing the IDLE instruction, because the PRCM module is under C64x software control. Therefore, the DSP CPU software can correctly skip some unnecessary parts of the pre-idle routine.

- State after reset for DSP CPU and DSP INTC registers:
  - The value of DSP CPU IER is 0x0.
  - The value of DSP CPU IFR is 0x0 because the interrupt selector default mapping is routing only emulation and unmapped events.
  - The SYS\_INTC\_INTMUXj registers (where j = 1 to 3): The default mapping is to route EVT<sub>x</sub> (where x = 0 to 3) on INT<sub>y</sub> (where y = 4 .. 15) (emulation and nonmapped events).
  - The value of the SYS\_INTC\_EVTMASK<sub>i</sub> registers (where i = 0 to 3) is 0x0 (all events are unmasked). The values of these registers are don't care because of the default interrupt selector mapping (the SYS\_INTC\_INTMUX<sub>j</sub> registers (where j = 1 to 3)).
  - The SYS\_INTC\_EVTFLAG<sub>i</sub> registers (where i = 0 to 3): These registers log the possible wake-up interrupt(s) (if more than one). At this stage, a new wake-up interrupt from device peripherals cannot be missed, because interrupts are level in the device, waiting for a software acknowledge (the user must clear the interrupt in the module to deassert the interrupt line).

For a complete description of the DSP CPU IER and IFR, see the C64x+ documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).

- State after reset for the WUGEN registers: two cases depending on the reset type:
  - In case of cold POR (the CORE power domain was in OFF state), the value of the [WUGEN\\_MEVT0](#) register is 0xFFFF FFFF, and the value of the [WUGEN\\_MEVT1](#) register is 0xFFFF, meaning that all interrupts are masked.
  - In case of warm POR (the CORE power domain was in ACTIVE state), the value of the [WUGEN\\_MEVT0](#) and [WUGEN\\_MEVT1](#) registers is the previous programmed one, enabling only wake-up interrupts.
- Programming model for a correct warm-reset:

The user must replay the noncombined events required for wakeup (if any):

1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
2. Restore the interrupt selector configuration:
  - (a) [SYS\\_INTC\\_INTMUXj](#) register (where j = 1 to 3)
  - (b) [SYS\\_INTC\\_EVTMASKi](#) register (optional, where i = 0 to 3)
  - (c) [SYS\\_INTC\\_INTDMASK](#) register (optional)
3. Replay the noncombined event captured in [SYS\\_INTC\\_EVTFLAGi](#) ( where i = 0 to 3):
 

For each DSP CPU interrupt, i = 4 to 15:

  - (a) Grab mapped event by setting the [SYS\\_INTC\\_INTMUXj\[6:0\]](#) INTSELi bit field (where j = 1 to 3).
  - (b) Check whether the event is combined (EVT0...3) or not combined (EVT4...127).
  - (c) If combined, exit the loop and go to the next loop iteration.
  - (d) If noncombined:
    - (i) Check whether the event is pending in the [SYS\\_INTC\\_EVTFLAGi](#) EFy bit (where i = 0 to 3, and y = 0 to 127).
    - (ii) If not pending, exit the loop and go to the next loop iteration.
    - (iii) If pending, set the associated IFi bit in the DSP CPU IFR.

---

**NOTE:** Software must ensure that an event is enabled only once in the interrupt selector/combiner of the DSP megamodule. If a noncombined event is mapped to an enabled DSP CPU interrupt, the associated combined event is masked in the associated [SYS\\_INTC\\_EVTMASKi](#) register (where i = 0 to 3) (and/or the combined event is not mapped to the DSP CPU interrupt). Reciprocally, if a combined event is mapped to a DSP CPU interrupt, all unmasked events in the associated [SYS\\_INTC\\_EVTMASKi](#) register (where i = 0 to 3) are not mapped as noncombined events to an enabled DSP CPU interrupt (through the DSP CPU IER).

---

Software program example for Step 3:

```

/* ----- */
/* Replays IFR bits associated to noncombined events */
/* Assumes interrupts globally disabled (GIE bit set to 0)*/
/* Assumes SYS_INTC.INTMUXj() and SYS_INTC.EVTFLAGi() are */
/* access macros to DSP megamodule IC registers */
/* ----- */
myIPR = IPR;
// save IPRfor(I=0; i<12; I++)
// for each CPU maskable interrupt{
myEvt = ( INTMUX( I >> 2 + 1 ) >> ( I & 0x3 ) << 3 ) & 0x7F;
if(myEvt >= 4)
// noncombined event
{
if( (EVTFLAG(myEvt >> 5 ) >> (myEvt & 0x1F ) ) & 0x1 )
{
myIPR |= ( 1<<(I+4) );
}
}
}

```

```

}
}}
IPR=myIPR;
// update IPR register
/* ----- */
/* Interrupts can be globally re-enabled from that point */
/* ----- */

```

4. Restore the CPU interrupt configuration by setting the DSP CPU IER accordingly.
5. Restore the DSP subsystem context (except saved return-PC).
6. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
7. Branch to saved return-PC.

For a complete description of the DSP CPU TSR, CSR, IER, or IFR, see the C64x+ documents listed in [Section 5.3.2.7, Other DSP Reference Documents](#).

- Procedure for a cold reset:
  1. Globally mask interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 0 (already done at boot time).
  2. Restore the interrupt selector configuration:
    - (a) SYS\_INTC\_INTMUXj register (where j = 1 to 3)
    - (b) SYS\_INTC\_EVTMASKi register (optional, where i = 0 to 3)
    - (c) [SYS\\_INTC\\_INTDMASK](#) register (optional)
  3. It is unnecessary to replay events, because they are masked in the [WUGEN\\_MEVT0](#) and [WUGEN\\_MEVT1](#) registers (default WUGEN configuration). This can be done to simplify the boot sequence without discriminating between cold reset and warm reset.
  4. Restore the CPU interrupt configuration by setting the DSP CPU IER accordingly.
  5. Restore the WUGEN context. This can be forced even in warm reset to simplify the boot sequence without discriminating between cold reset and warm reset.

---

**NOTE:** If Step 3 and Step 5 are performed systematically, the boot code can be shared between warm reset and cold reset boot without programming two distinct software boot codes.

---

6. Restore the rest of the DSP subsystem context (except saved return-PC).
7. Globally enable the interrupts by setting the DSP CPU TSR[0] or CSR[0] GIE bit to 1.
8. Branch to saved return-PC.

## 5.4.5 Memory Management

### 5.4.5.1 External Memory

#### 5.4.5.1.1 Cacheability

The [SCACHE\\_CONFIG](#) and [SCACHE\\_OCP](#) registers are used to configure the caches.

#### 5.4.5.1.2 Virtual Addressing

The device embeds an instance of MMU dedicated to the DSP (DSP MMU). For more information about DSP MMU software settings at DSP boot, see [Section 5.4.1.2, Example of DSP Boot](#).

For a programming guide of the DSP MMU, see [Chapter 20, Memory Management Units](#).

## 5.4.6 DSP Power Management

### 5.4.6.1 Clock Management

#### 5.4.6.1.1 Clock Configuration

The DSP subsystem receives one single-clock signal (DSP\_CLK) from the PRCM module.

From the DSP\_CLK functional clock, internal clocks (CD0\_CLK and CD1\_CLK) are generated by the DSP DPLL and SYSC.

For a complete description of the PRCM module registers used to configure these clocks, see [Section 3.6, Clock Management Functional Description](#) in [Chapter 3, Power, Reset, and Clock Management](#).

#### 5.4.6.1.2 Clock Gating

- DSP subsystem:

The DSP internal clocks can be hardware-disabled by the PRCM module when the MSTANDBY/WAIT handshake protocol occurs. To configure the PRCM module so that DSP internal clocks are hardware-supervised, set the corresponding PRCM.CM\_AUTOIDLE\_xxx bit field to 0x1.

When the DSP subsystem does not require its internal clocks, they can be disabled at the PRCM module level by setting the corresponding PRCM.CM\_FCLKEN\_xxx bit field to 0.

For a complete description of the PRCM module registers, see [Chapter 3, Power, Reset, and Clock Management](#).

- SYSC module:

The DSP SYSC module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state operates with no penalty for cycle latency.

Automatic clock-gating is enabled by setting the [SYSC\\_SYSCONFIG\[0\] AUTOIDLE](#) bit to 1 (default value). This feature can be disabled by setting the [SYSC\\_SYSCONFIG\[0\] AUTOIDLE](#) bit to 0, which makes the clock free-running.

- WUGEN module:

The DSP WUGEN module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-gated to clock-nongated state operates with no penalty for cycle latency.

Automatic clock gating is enabled by setting the [WUGEN\\_SYSCONFIG\[0\] AUTOIDLE](#) bit to 1 (default value). The clock can be made free-running by setting the [WUGEN\\_SYSCONFIG\[0\] AUTOIDLE](#) bit to 0.

- TPCC from the eDMA module:

The eDMA (or TPCC) module implements automatic clock gating on internal hardware detection of the absence of activity. The transition from clock-nongated to clock-gated state operates with no penalty for cycle latency.

Automatic clock gating is enabled by default. It can be disabled by setting the [TPCC\\_CLKGDIS\[0\] CLKGDIS](#) bit to 1. In this case, all TPCC internal clocks are free-running.

---

**NOTE:** To save power, it is recommended to not disable TPCC clock gating and to leave the [TPCC\\_CLKGDIS](#) register at its reset value.

---

#### 5.4.6.2 Reset Management

In addition to hardware reset signals generated by the PRCM module, the DSP subsystem can be reset by software control.

For a complete description of the PRCM module registers, see [Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

---

**NOTE:** Software reset can be applied only while the DSP subsystem is in clock-off mode.

---

### 5.4.6.3 Power Down and Wakeup Management

- DSP megamodule power-down controller (PDC):  
The DSP megamodule embeds a PDC block that allows power-down management by software. Individual DSP megamodule blocks such as DSP CPU, PMC, DMC, EMC, and shared cache can be powered off by the PDC.
- This software control is ensured by the [SYS\\_PD\\_PDCCMD](#) register:
  - By setting the [SYS\\_PD\\_PDCCMD](#)[16] GEMPD bit to 1, the user enables power-down management during idle mode.
  - By setting the [SYS\\_PD\\_PDCCMD](#)[1:0] xMCLOG and [SYS\\_PD\\_PDCCMD](#)[1:0] xMCMEM bit fields (where x = {P, D, U}), the user controls the XMC clock-gating and standby memory modes. For example, DMC is controlled with the [SYS\\_PD\\_PDCCMD](#)[5:4] DMCLOG and [SYS\\_PD\\_PDCCMD](#)[7:6] xMCMEM bit fields.
- The programming sequence for transition to clock-off state is:

Before executing the IDLE instruction, the following sequence must be performed:

1. Write 1 to the [SYS\\_PD\\_PDCCMD](#)[16] GEMPD bit (STANDBY state); by default, the values of the [SYS\\_PD\\_PDCCMD](#)[1:0] xMCLOG and [SYS\\_PD\\_PDCCMD](#)[1:0] xMCMEM bit fields (where x = {P, D, U}) are 0x1 so that module clock gating is enabled and the standby mode of memories is statically activated after the IDLE instruction executes.
2. Mask all interrupts not intended to wake up the DSP subsystem.
3. Program the PRCM module so that the DSP clocks are cut on DSP standby. For more information, see [Section 3.1.1.1.2, Module-Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#)
4. Read back all the written registers to ensure write completion.
5. Confirm that no user-initiated cache coherence operations are in progress.
6. Ensure that the IDLE code sequence is in L1 or L2.

The user must also ensure that no other instruction is executed parallel to the IDLE instruction.

- The programming sequence for transition to power-off state is:  
Before executing the IDLE instruction, the following sequence must be performed:
  1. Save the MMU context in external memory.
  2. Save the DMA context in external memory.
  3. Disable the nonwakeable interrupt in the INTC.
  4. Enable the wakeable interrupt in the INTC.
  5. Initialize the wakeable INTC.
  6. Enable the wakeable interrupt in the wake-up generator (the WUGEN\_MEVTCLR<sub>i</sub> register, where i = 0 to 4)
  7. Check the [SYSC\\_BOOTADDR](#)[31:10] BOOTLOADADDR bit field.
  8. Configure the DSP PDC.
  9. Instruct the MPU to shut down the DSP subsystem.
  10. Execute the IDLE instruction.

The user must also ensure that no other instruction is executed parallel to the IDLE instruction. When the DSP subsystem is ready to go to off mode, there are two ways to completely shut down the DSP subsystem:

- DSP power off force mode (MPU):
  1. Clear [PM\\_PWSTCTRL\\_DSP](#) POWERSTATE to 0x0 (off mode).
  2. Set [CM\\_CLKSTCTRL\\_DSP](#) CLKTRCTRL\_DSP to 0x1 (software sleep transition).
  3. Set the [PM\\_WKDEP\\_DSP](#) register to 0x0 to remove power domain dependencies.

4. Clear CM\_FCLKEN\_DSP EN\_DSP to 0x0 (DSP\_CLK is disabled).  
DSP then enters off mode.
- DSP power off auto mode (MPU or DSP):
  1. Clear PM\_PWSTCTRL\_DSP POWERSTATE to 0x0 (off mode).
  2. Set the CM\_CLKSTCTRL\_DSP CLKTRCTRL\_DSP register to 0x3 (hardware auto sleep transition).
  3. Set the PM\_WKDEP\_DSP register to 0x0 to remove power domain dependencies.  
DSP is put in off mode when the IDLE instruction executes.

#### **CAUTION**

The DSP clock must not be stopped manually; otherwise, the WUGEN inside the DSP has no functional clock and cannot wake up the DSP subsystem.

When the DSP is shut down, it can be wakened by an external event. The boot code executed after wakeup must include at least the following steps:

1. Configure L1 and L2 caches.
2. Restore the MMU context from external memory.
3. Restore the DMA context from external memory.
4. Enable interrupts in the INTC.

### **5.4.7 Error Identification Process**

Several mechanisms are available in the DSP subsystem to report errors at different levels.

#### **5.4.7.1 Error Reporting for eDMA**

The TPTC and TPCC blocks of the eDMA module also contain registers to inform the user of a problem during DSP external DMA communication.

##### **TPCC block**

The TPCC provides one error interrupt output, CCERRINT (EVT38; see [Table 5-6](#)), which consolidates the following error conditions:

- QDMA missed events (stored in the [TPCC\\_QEMR](#))
- DMA missed events (stored in the [TPCC\\_EMR](#))
- Transfer completion code error (stored in the [TPCC\\_CCERR](#)[16] TCCERR bit)
- Queue threshold error events (stored in the [TPCC\\_CCERR](#)[n] QTHRXCdn bit, where n = 0, 1)

When an error is detected, the CCERRINT event is asserted, because error events do not have enables.

---

**NOTE:** The CCERRINT event follows the same convention as other TPCC interrupt outputs. When the error interrupt condition transitions from a no-errors-are-set state to at least one error set, the error output (CCERRINT) pulses high for one TPCC clock cycle. If additional errors are latched before the original error is cleared by the user, the TPCC does not generate additional interrupt pulses. Software must poll all bits during execution of the ISR and clear all error conditions so that subsequent error pulses can be generated by the TPCC block.

---

Error interrupts can be set and/or reevaluated by writes to the [TPCC\\_EEVAL](#) register.

##### **TPTC block**

Each TPTC can also detect several error conditions:

- Read status or write status errors in the [TPTC\\_ERRSTAT](#)[0] BUSERR bit
- TR error in the [TPTC\\_ERRSTAT](#)[2] TRERR bit

- MMR address error in the [TPTC\\_ERRSTAT\[3\]](#) MMRAERR bit

Errors are recorded in the [TPTC\\_ERRSTAT](#) register, regardless of whether they are enabled. They can be cleared from the [TPTC\\_ERRSTAT](#) register only by writing 1 to the corresponding bit of the [TPTC\\_ERRCLR](#) register.

The error details register ([TPTC\\_ERRDET](#)) contains additional information about the first read status error or write status error detected. Future errors are bit-recorded until the [TPTC\\_ERRDET](#) register is cleared.

If read status and write status are returned to the TPTC in the same cycle, the value of the read or write status that has an error (nonzero) is latched in the [TPTC\\_ERRDET](#) register, and the [TPTC\\_ERRSTAT\[0\]](#) BUSERR bit is set. If both the read and write status are nonzero, the write status is given priority for setting the [TPTC\\_ERRDET](#) register. The [TPTC\\_ERRDET](#) register is cleared by setting the [TPTC\\_ERRCLR\[0\]](#) BUSERR bit to 1.

If an error is enabled (by the [TPTC\\_ERREN](#) register), the first occurrence of an enabled error generates a pulsed interrupt to the CPU by the TCERRINT event output (TCERRINT0 with EVT39 for TPTG0, and TCERRINT1 with EVT40 for TPTG1, respectively; see [Table 5-6](#)). Subsequent errors do not generate a new pulse until all accumulated errors are cleared by the CPU. The CPU clears bits in the [TPTC\\_INTSTAT](#) register by writing 1 to the corresponding bit(s) of the TPTC\_NTCLR register.

#### 5.4.7.2 Error Reporting for the L3 Interconnect

L3 interconnect out-of-band errors are also reported by the external L3 interrupt signal. This signal corresponds to the EVT84 event and is directly connected to the DSP\_nIRQ[39] DSP CPU interrupt line. For more information about L3 interconnect error reporting, see [Section 13.2, L3 Interconnect](#) in [Chapter 13, Interconnect](#).

## 5.5 DSP Subsystem Register Manual

### 5.5.1 DSP Subsystem Instance Summary

**Table 5-8. DSP Subsystem Instance Summary**

Module Name	Physical Address	Size
SYS_INTC	0x0180 0000	64KB
SYS_PD	0x0181 0000	64KB
EDM	0x01BC 0000	4KB
TPCC	0x01C0 0000	64KB
TPTC0	0x01C1 0000	1KB
TPTC1	0x01C1 0400	1KB
SYSC	0x01C2 0000	4KB
WUGEN	0x01C2 1000	4KB
L1_SCACHE	0x01C3 0000	256 bytes
L2_SCACHE	0x01C3 0200	256 bytes
SCACHE_SCTM	0x01C3 0400	512 bytes
SCACHE_MMU	0x01C3 0800	2KB

#### CAUTION

The SCACHE\_MMU registers are limited to 32-bit data access; 16- and 8-bit access are not allowed and can corrupt register content.

### 5.5.2 DSP Subsystem Logical Register Mapping

<a href="#">SYS_PD_REVID</a>	R	32	0x0000 2000	0x0181 2000

<sup>(1)</sup> i = 0 to 7

### 5.5.4.2 SYS\_PD Register Description

**Table 5-90. SYS\_PD\_PDCCMD**

<b>Address Offset</b>	0x0000 0000	<b>Instance</b>	SYS_PD
<b>Physical Address</b>	<a href="#">0x0181 0000</a>		
<b>Description</b>	Power-Down Command Register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GEMPD	EMCMEM	EMCLOG	UMCMEM	UMCLOG	DMCMEM	DMCLOG	PMCMEM	PMCLOG							

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Reserved.	R	0x0000
16	GEMPD	Power-down during IDLE: GEMPD = 0: Normal operation. Do not power-down CPU or GEM when CPU is IDLE. GEMPD = 1: Sleep mode. Power-down CPU and GEM when CPU enters IDLE state	RW	0
15:14	EMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the EMC for powering-down internal memories.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1

Bits	Field Name	Description	Type	Reset
13:12	EMCLOG	Logic Clock Gating Modes. Determines to what degree the EMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating.  0x1: Static clock gating of unused modules regions when GEM is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when GEM is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
11:10	UMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the UMC for powering-down L2 pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
9:8	UMCLOG	Logic Clock Gating Modes. Determines to what degree the UMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating.  0x1: Static clock gating of unused modules regions when GEM is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when GEM is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
7:6	DMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the DMC for powering-down L1D pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
5:4	DMCLOG	Logic Clock Gating Modes. Determines to what degree the DMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating.  0x1: Static clock gating of unused modules regions when GEM is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when GEM is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1
3:2	PMCMEM	SRAM Sleep Modes Determines the RAM sleep modes used by the PMC for powering-down L1P pages.  0x0: No sleep mode supported 0x1: Sleep mode 1 Write 0x2: Sleep mode 2 - equivalent to sleep mode 1 Write 0x3: Sleep mode 3 - equivalent to sleep mode 1	RW	0x1
1:0	PMCLOG	Logic Clock Gating Modes. Determines to what degree the PMC gates its clock internally.  0x0: No clock gating supported beyond leaf clock gating.  0x1: Static clock gating of unused modules regions when GEM is active (pmc_pd_pdstat[1:0] = 00) and Static clock gating when GEM is in standby (pmc_pd_pdstat[1:0] = 11)	RW	0x1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SET	EVAL														

Bits	Field Name	Description	Type	Reset
31:2	RESERVED	write 0's for future compatibility	W	0x0000 0000
1	SET	Error Interrupt Set: CPU write of 1 to the SET bit causes the TPCC error interrupt to be pulsed regardless of state of <a href="#">TPCC_EMR/TPCC_EMRH</a> , <a href="#">TPCC_QEMR</a> , or CPU write of 0 has no effect.	W	0
0	EVAL	Error Interrupt Evaluate: CPU write of 1 to the EVAL bit causes the TPCC error interrupt to be pulsed if any errors have not been cleared in the <a href="#">TPCC_EMR/TPCC_EMRH</a> , <a href="#">TPCC_QEMR</a> , or <a href="#">TPCC_CCERR</a> registers. CPU write of 0 has no effect.	W	0

**Table 5-180. TPCC\_CERH**

<b>Address Offset</b>	0x0000 101C	<b>Instance</b>	TPCC
<b>Physical Address</b>	0x01C0 101C		
<b>Description</b>	Chained Event Register (High Part): If <a href="#">TPCC_CERH[n] En</a> bit is set (regardless of state of <a href="#">TPCC_EERH[n] En</a> ), then the corresponding DMA channel is prioritized vs. other pending DMA events for submission to the <a href="#">TPCC_CERH[n] En</a> bit is set when a chaining completion code is returned from one of the TPTCs via the completion interface, or is generated internally via Early Completion path. <a href="#">TPCC_CERH[n] En</a> bit is cleared when the corresponding event is prioritized and serviced. If the <a href="#">TPCC_CERH[n] En</a> bit is already set and the corresponding chaining completion code is returned from the TC, then the corresponding bit in the Event Missed Register is set. <a href="#">TPCC_CERH[n] En</a> cannot be set or cleared via software.

<b>Address Offset</b>	0x0000 1084		
<b>Physical Address</b>	0x01C0 1084	<b>Instance</b>	TPCC
<b>Description</b>	QDMA Event Enable Register: Enabled/disabled QDMA address comparator for QDMA Channel N. TPCC_QEER[n] En is not directly writeable. QDMA channels can be enabled via writes to TPCC_QEESR and can be disabled via writes to TPCC_QEECR register. TPCC_QEER[n] En = 1, The corresponding QDMA channel comparator is enabled and Events will be recognized and latched in TPCC_QER[n] En. TPCC_QEER[n] En = 0, The corresponding QDMA channel comparator is disabled. Events will not be recognized/latched in TPCC_QER[n] En.

**Table 5-252. TPCC\_EER\_RN\_k**

<b>Address Offset</b>	0x0000 2020 + (0x200 * k)		
<b>Physical Address</b>	0x01C0 2020 + (0x200 * k)	<b>Instance</b>	TPCC
<b>Description</b>	Event Enable Register: Enables DMA transfers for TPCC_ER[n] En pending events. TPCC_ER[n] En is set based on externally asserted events (via tpcc_eventN_pi). This register has no effect on Chained Event Register (TPCC_CER) or Event Set Register (TPCC_ESR). Note that if a bit is set in TPCC_ER[n] En while TPCC_EER[n] En is disabled, no action is taken. If TPCC_EER[n] En is enabled at a later point (and TPCC_ER[n] En has not been cleared via software) then the event will be recognized as a valid 'TR Sync'. TPCC_EER[n] En is not directly writeable. Events can be enabled via writes to TPCC_EESR and can be disabled via writes to TPCC_EECR register. TPCC_EER[n] En = 0: TPCC_ER[n] En is not enabled to trigger DMA transfers. TPCC_EER[n] En = 1: TPCC_ER[n] En is enabled to trigger DMA transfers.

Bits	Field Name	Description	Type	Reset
31	PRIV	Privilege level: privilege level (supervisor vs. user) for the host/cpu/dma that programmed this PaRAM Entry. Value is set with the vbus priv value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus. 0 : User level privilege 1 : Supervisor level privilege	R	-
30	RESERVED	Reserved	R	0
29:28	RESERVED	write 0's for future compatibility reads return 0's	RW	0bxx
27:24	PRIVID	Privilege ID: Privilege ID for the external host/cpu/dma that programmed this PaRAM Entry. This value is set with the vbus privid value when any part of the PaRAM Entry is written. Not writeable via vbus wdata bus. Is readable via VBus rdata bus.	R	0x-
23	ITCCHEN	Intermediate transfer completion chaining enable: 0: disabled 1: enabled.	RW	-
22	TCCHEN	Transfer complete chaining enable: 0: disabled 1: enabled.	RW	-
21	ITCINTEN	Intermediate transfer completion interrupt enable: 0: disabled. 1: enabled (corresponding <a href="#">TPCC_IER</a> bit must be set to 1 to generate interrupt)	RW	-
20	TCINTEN	Transfer complete interrupt enable: 0: disabled. 1: enabled (corresponding <a href="#">TPCC_IER</a> bit must be set to 1 to generate interrupt)	RW	-
19	WIMODE	Backward compatibility mode: 0: Normal operation 1 : WI Backwards Compatibility mode, forces BCNT to be adjusted by 1 upon TR submission (0 means 1, 1 means 2, ... ) and forces ACNT to be treated as a word-count (left shifted by 2 by hardware to create byte cnt for TR submission)	RW	-

Bits	Field Name	Description	Type	Reset
18	RESERVED	write 0's for future compatibility reads return 0's	RW	-
17:12	TCC	Transfer Complete Code: The 6-bit code is used to set the relevant bit in <a href="#">TPCC_CER</a> for chaining or in <a href="#">TPCC_IER</a> for interrupts.	RW	0bxxxxxx
11	TCCMODE	Transfer complete code mode: Indicates the point at which a transfer is considered completed. Applies to both chaining and interrupt. 0: Normal Completion, A transfer is considered completed after the transfer parameters are returned to the CC from the TC (which was returned from the peripheral). 1: Early Completion, A transfer is considered completed after the CC submits a TR to the TC. CC generates completion code internally .	RW	-
10:8	FWID	FIFO width: Applies if either SAM or DAM is set to FIFO mode. Pass-thru to TC.  0x0: FIFO width is 8-bit 0x1: FIFO width is 16-bit 0x2: FIFO width is 32-bit 0x3: FIFO width is 64-bit 0x4: FIFO width is 128-bit 0x5: FIFO width is 256-bit	RW	0bxxx
7:4	RESERVED	write 0's for future compatibility reads return 0's	RW	0x-
3	STATIC	Static Entry: 0: Entry is updated as normal 1: Entry is static, Count and Address updates are not updated after TRP is submitted. Linking is not performed.	RW	-
2	SYNCDIM	Transfer Synchronization Dimension: 0: A-Sync, Each event triggers the transfer of ACNT elements. 1: AB-Sync, Each event triggers the transfer of BCNT arrays of ACNT elements	RW	-
1	DAM	Destination Address Mode: Destination Address Mode within an array. Pass-thru to TC. 0: INCR, Dst addressing within an array increments. Dst is not a FIFO. 1: FIFO, Dst addressing within an array wraps around upon reaching FIFO width.	RW	-
0	SAM	Source Address Mode: Source Address Mode within an array. Pass-thru to TC. 0: INCR, Src addressing within an array increments. Source is not a FIFO. 1: FIFO, Src addressing within an array wraps around upon reaching FIFO width.	RW	-

BCNT																ACNT															

Bits	Field Name	Description	Type	Reset
31:16	BCNT	Count for 2nd Dimension: BCNT is a 16-bit unsigned value that specifies the number of arrays of length ACNT. For normal operation, valid values for BCNT can be anywhere between 1 and 65535. Therefore, the maximum number of arrays in a frame is 65535 (64K-1 arrays). BCNT=1 means 1 array in the frame, and BCNT=0 means 0 arrays in the frame. In normal mode, a BCNT of 0 is considered as either a Null or Dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set, then the programmed BCNT value will be incremented by 1 before submission to TC. that is, 0 means 1, 1 means 2, 2 means 3, ..., 0xFFFFE means 0xFFFF. A value of 0xFFFF is an illegal value that will be treated as a Null TR.	RW	0x----

Bits	Field Name	Description	Type	Reset
15:0	ACNT	number of bytes in 1st dimension: ACNT represents the number of bytes within the first dimension of a transfer. ACNT is a 16-bit unsigned value with valid values between 0 and 65535. Therefore, the maximum number of bytes in an array is 65535 bytes (64K-1 bytes). ACNT must be greater than or equal to 1 for a TR to be submitted to TC. An ACNT of 0 is considered as either a null or dummy transfer. A Dummy or Null transfer will generate a Completion code depending on the settings of the completion bit fields of the OPT field. If the OPT.WIMODE bit is set then the ACNT field represents a word count. The CC must internally multiply by 4 to translate the word count to a byte count prior to submission to the TC. The 2 MSBs of the 16-bit ACNT are reserved and should always be written as 'b00 by the user. If user writes a value other than 0, it will still be treated as 0 since the multiply-by-4 operation (to translate between a word count and a byte count) will drop the 2 msbits. For dummy and null transfer definition, the ACNT definition will disregard the 2 msbits. that is, a programmed ACNT value of 0x8000 in WI-mode will be treated as 0 byte transfer, resulting in null or dummy operation dependent on the state of BCNT and CCNT. <b>Description</b>	Link and Reload parameters			
<b>Type</b>	RW			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BCNTRLD																LINK															

Bits	Field Name	Description	Type	Reset
31:16	BCNTRLD	BCNT Reload: BCNTRLD is a 16-bit unsigned value used to reload the BCNT field once the last array in the 2nd dimension is transferred. This field is only used for A-Sync'ed transfers. In this case, the CC decrements the BCNT value by one on each TR submission. When BCNT (conceptually) reaches zero, then the CC decrements CCNT and uses the BCNTRLD value to reinitialize the BCNT value. For AB-synchronized transfers, the CC submits the BCNT in the TR and therefore the TC is responsible to keep track of BCNT, not thus BCNTRLD is a don't care field.	RW	0x----

Bits	Field Name	Description	Type	Reset
15:0	LINK	<p>Link Address: The CC provides a mechanism to reload the current PaRAM Entry upon its natural termination (that is, after count fields are decremented to 0) with a new PaRAM Entry. This is called 'linking'. The 16-bit parameter LINK specifies the byte address offset in the PaRAM from which the CC loads/reloads the next PaRAM entry in the link. The CC should disregard the value in the upper 2 bits of the LINK field as well as the lower 5-bits of the LINK field. The upper two bits are ignored such that the user can program either the 'literal' byte address of the LINK parameter or the 'PaRAM base-relative' address of the link field. Therefore, if the user uses the literal address with a range from 0x4000 to 0x7FFF, it will be treated as a PaRAM-base-relative value of 0x0000 to 0x3FFF. The lower-5 bits are ignored and treated as 'b00000, thereby guaranteeing that all Link pointers point to a 32-byte aligned PaRAM entry. In the latter case (5-lsbs), behavior is undefined for the user (that is, don't have to test it). In the former case (2 msbs), user should be able to take advantage of this feature (that is, do have to test it). If a Link Update is requested to a PaRAM address that is beyond the actual range of implemented PaRAM, then the Link will be treated as a Null Link and all 0s plus 0xFFFF will be written to the current entry location. A LINK value of 0xFFFF is referred to as a NULL link which should cause the CC to write 0x0 to all entries of the current PaRAM Entry except for the LINK field which is set to 0xFFFF. The Priv/Privid state is overwritten to 0x0 when linking. MSBs and LSBS should not be masked when comparing against the 0xFFFF value. that is, a value of 0x3FFE is a non-NULL PaRAM link field.</p>	RW	0x----

RESERVED																DFSTRPTR	RESERVED				ACTV	RESERVED	DSTACTV				RESERVED	WSACTV	SRACTV	PROGBUSY	

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	reads return 0's	R	0x00000
13:12	DFSTRTPTR	Dst FIFO Start Pointer Represents the offset to the head entry of Dst Register FIFO, in units of *entries*. Legal values = 0x0 to 0x3	R	0x0
11:9	RESERVED	reads return 0's	R	0x0
8	ACTV	Channel Active Channel Active is a logical-OR of each of the *BUSY/ACTV signals. The ACTV bit must remain high through the life of a TR. 0 : Channel is idle. 1 : Channel is busy.	R	1
7	RESERVED	reads return 0's	R	0
6:4	DSTACTV	Destination Active State Specifies the number of TRs that are resident in the Dst Register FIFO at a given instant. Legal values are constrained by the DSTREGDEPTH parameter. Read 0x0: FIFO set is empty. Read 0x1: Dst FIFO contains 1 TR Read 0x2: Dst FIFO contains 2 TR Read 0x3: Dst FIFO contains 3 TR Read 0x4: Dst FIFO contains 4 TR	R	0x0
3	RESERVED	reads return 0's	R	0
2	WSACTV	Write Status Active 0 : Write status is not pending. Write status has been received for all previously issued write commands. 1 : Write Status is pending. Write status has not been received for all previously issued write commands.	R	0
1	SRCACTV	Source Active State 0 : Source Active set is idle. Any TR written to Prog Set will immediately transition to Source Active set as long as the Dst FIFO Set is not full (DSTFULL == 1). 1 : Source Active set is busy either performing read transfers or waiting to perform read transfers for current Transfer Request.	R	0
0	PROGBUSY	Program Register Set Busy 0 : Prog set idle and is available for programming. 1 : Prog set busy. User should poll for PROGBUSY equal to 0 prior to re-programming the Program Register set.	R	0

<b>Address Offset</b>	0x0000 0100 + (0x4 * i)		
<b>Physical Address</b>	0x01C3 0500 + (0x4 * i)	<b>Instance</b>	SCACHE_SCTM
<b>Description</b>	These registers contain the control and status settings for a single counter in the module. There will be a CTCR for every counter in the module (WT: with timer)		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								INPSEL				RESERVED				RESTART	DBG	INT	CHNSDW	OVRFLW	IDLE	FREE	DURMODE	CHAIN	RESET	ENBL					

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Reserved.	R	0x000
20:16	INPSEL	Counter Timer input selection 0: Constantly asserted input that results in a free-running counter/timer 1-31: Index of event input signal selected	RW	0x00
15:11	RESERVED	Reserved.	R	0x00
10	RESTART	Restart the timer after an interval match 0: The timer stops after the first interval match. It must be manually reset by software before it starts counting again (run-once timer mode). 1: The timer immediately resets to 0 and begins incrementing again based on the current input configuration (restart timer mode).	RW	0
9	DBG	Signal debug logic on interval match 0: No debug event is generated. 1: Upon interval match, generates a debug event on the corresponding debug output event signal	RW	0
8	INT	Generate interrupt on interval match 0: No interrupt is generated. 1: Upon interval match, generates an interrupt on the corresponding interrupt output event signal	RW	0
7	CHNSDW	Counter has a shadow register for chain reads. 0: The read of the corresponding counter register returns the current value. 1: Read of the high-order counter register, simultaneously loads the current value of the 32 LSBs into a shadow register. The read of the counter register that corresponds to this counter returns the value of the shadow register. This is applicable only when the counter is chained.	R	0
6	OVRFLW	Counter has wrapped since it was last read 0: The counter has not wrapped since the last read. 1: The counter has wrapped since the last read.	R	0
5	IDLE	Counter ignores processor IDLE state 0: The counter does not increment during IDLE state. 1: The counter continues to function during IDLE state; applicable if IDLEMODE = 1.	RW	0
4	FREE	Counter ignores processor debug halt state 0: The counter does not increment (decrement) during the debug halt state.	RW	0

Bits	Field Name	Description	Type	Reset
		1: The counter continues to function during debug halt state.		
3	DURMODE	Counter is in duration or occurrence mode  0: The counter operates in event mode. The counter increments by 1 each time a rising edge is seen on the designated input event signal.  1: The counter operates in duration mode. The counter increments every time a clock cycle is seen and the corresponding input event signal is asserted.	RW	0
2	CHAIN	Counter is chained to an adjacent counter  0: The counter is not chained.  1: Reserved	RW	0
1	RESET	Counter reset control  0: No effect  1: The corresponding counter is reset to the initial value and the OVERFLW bit is cleared. It continues to function if it is still enabled.	RW	0
0	ENBL	Counter enable control  0: The counter does not increment.  1: The counter increments as configured.	RW	0

## ***IVA-HD Subsystem***

---

---

---

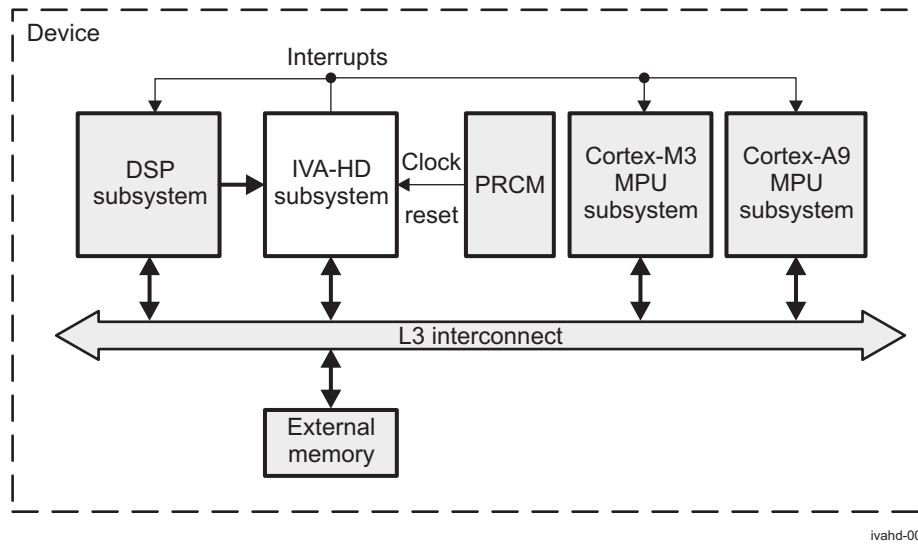

This chapter describes the IVA-HD subsystem in the multimedia device.

<b>Topic</b>	<b>Page</b>
<b>6.1 IVA-HD Overview .....</b>	<b>1475</b>

## 6.1 IVA-HD Overview

The IVA-HD is the image and video imaging hardware accelerator subsystem. Figure 6-1 shows the IVA-HD subsystem in the device.

**Figure 6-1. IVA-HD in the Device**

The IVA-HD supports resolutions up to 1080 p/i with full performance of 30 fps (or 60 fields). The IVA-HD subsystem supports the following codec standards natively; that is, all functions of standards are accelerated (without any intervention of the digital signal processor [DSP]):

- H.264: BP/MP/HP Encode and Decode
- H.264: Fast Profile/RCDO Encode and Decode
- MPEG-4: SP/ASP Encode/Decode (No support for GMC)
- DivX 5.x and higher Encode/Decode (No lower version; for example, 3.11 and 4.x)
- H.263: Profile 0 and 3 for Decode, Profile 0 for Encode
- Sorenson Spark: V0 and V1 Decode (No encode support)
- MPEG-2 SP/MP Encode/Decode
- MPEG-1 Encode/Decode
- VC-1/WMV9/RTV : SP/MP/AP Encode and Decode
- On2® VP6/VP7 Decode
- RealVideo® 8/9/10 Decode
- AVS 1.0 Encode and Decode
- JPEG (also MJPEG) Baseline Encode/Decode
- H.264 Annex G (SVC) Scalable Baseline Profile to 480p – 720p30
- H.264 Annex H (MVC) up to 720p30

The IVA-HD subsystem is composed of:

- A primary sequencer, including its memories and an interrupt controller: iCONT1
- A video direct memory access (DMA) processor, which can be used as a secondary sequencer: iCONT2
- A video DMA engine: vDMA
- An entropy coder/decoder: ECD3
- A motion compensation engine: MC3
- A transform and quantization calculation engine: CALC3
- A loop filter acceleration engine: iLF3

- A motion estimation acceleration engine: iME3
- An intraprediction estimation engine: iPE3
- Shared level 2 (L2) interface and memory
- Local interconnect
- A message interface for communication between SyncBoxes
- Mailbox
- A debug module for trace event and software instrumentation: SMSET

IVA-HD 1.0 will use eXpressDSP Digital Media (xDM) standard as the principle software interface. The xDM standard defines application programming interfaces (APIs) through which an application invokes a particular class of codec, such as video decode or audio encode.

xDM developers kit, technical documentation and full compliant codecs can be downloaded from <http://focus.ti.com/docs/toolsw/folders/print/tmdxdaisxdm.html>.

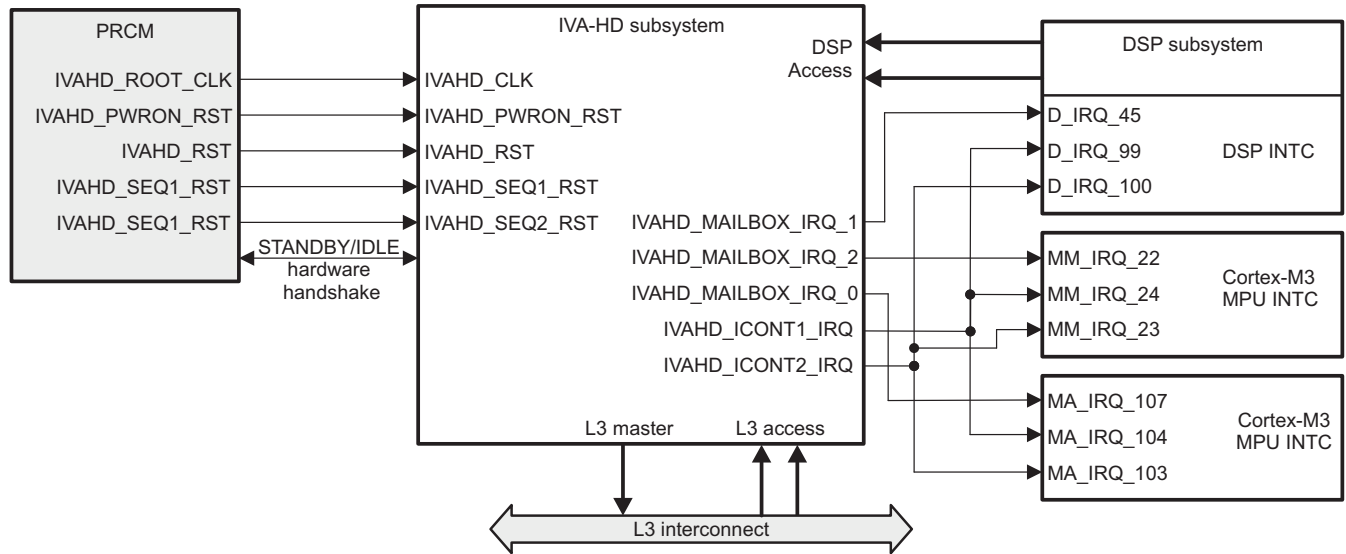

Software released on IVA-HD 1.0 will be xDM-compliant and will be available during 2010.

### 6.1.1 IVA-HD Integration

This section describes IVA-HD in the device, including information about clocks, resets, and hardware requests.

Figure 6-2 shows IVA-HD integration.

Figure 6-2. IVA-HD Integration

iva-hd-002

**NOTE:** For more information about the STANDBY/IDLE hardware handshake and the wake-up request, see Section 3.1.1.1.2, *Module-Level Clock Management*, in Chapter 3 *Power, Reset and Clock Management*.

Table 6-1 through Table 6-3 summarize the integration of the module in the device.

Table 6-1. IVA-HD Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
IVA-HD	PD_IVAHD	L3

Table 6-2. IVA-HD Clocks and Resets

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
IVA-HD	IVAHD_CLK	IVAHD_ROOT_CLK	CM	IVA-HD clock (functional and interface)
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
IVA-HD	IVAHD_PWRON_RST	IVAHD_PWRON_RST	PRM	IVA-HD power-on reset
IVA-HD	IVAHD_RST	IVAHD_RST	PRM	IVA-HD global reset (all logic is reset)
IVA-HD	IVAHD_SEQ1_RST	IVAHD_SEQ1_RST	PRM	iCONT1 reset
IVA-HD	IVAHD_SEQ2_RST	IVAHD_SEQ2_RST	PRM	iCONT2 reset

**Table 6-3. Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
IVA-HD	IVAHD_MAILBOX_IRQ_0	MA_IRQ_107	Cortex™-A9 MPU INTC	IVA-HD mailbox user 0 interrupt
IVA-HD	IVAHD_ICONT1_IRQ	MA_IRQ_104	Cortex-A9 MPU INTC	Sync interrupt from iCONT1
IVA-HD	IVAHD_ICONT2_IRQ	MA_IRQ_103	Cortex-A9 MPU INTC	Sync interrupt from iCONT2
IVA-HD	IVAHD_MAILBOX_IRQ_1	D_IRQ_45	DSP INTC	IVA-HD mailbox user 1 interrupt
IVA-HD	IVAHD_ICONT1_IRQ	D_IRQ_99	DSP INTC	Sync interrupt from iCONT1
IVA-HD	IVAHD_ICONT2_IRQ	D_IRQ_100	DSP INTC	Sync interrupt from iCONT2
IVA-HD	IVAHD_MAILBOX_IRQ_2	MM_IRQ_22	Cortex™-M3 MPU INTC	IVA-HD mailbox user 2 interrupt
IVA-HD	IVAHD_ICONT1_IRQ	MM_IRQ_24	Cortex-M3 MPU INTC	Sync interrupt from iCONT1
IVA-HD	IVAHD_ICONT2_IRQ	MM_IRQ_23	Cortex-M3 MPU INTC	Sync interrupt from iCONT2

**NOTE:**

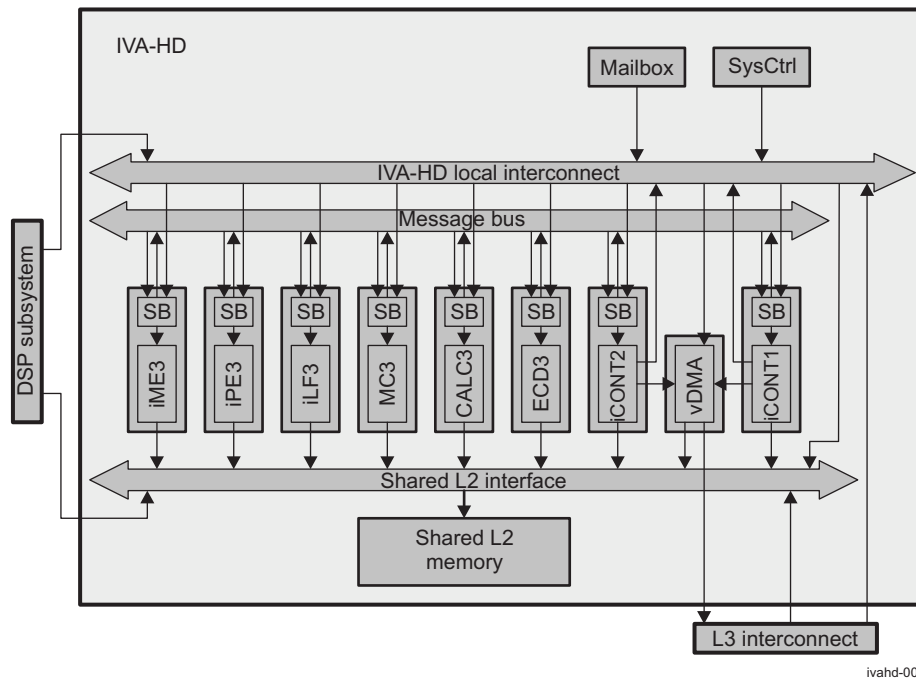

- For more information about the mailbox interrupt, see [Section 19.3.4](#).

## 6.1.2 IVA-HD Functional Description

### 6.1.2.1 IVA-HD Block Diagram

[Figure 6-3](#) shows a block diagram of the IVA-HD subsystem.

Figure 6-3. IVA-HD Block Diagram

NOTE: SB stands for SyncBox.

NOTE: iPE3, MC3, CALC3, and ECD3 include a load and store engine (LSE), which is the same in each of these modules.

### 6.1.2.1.1 SyncBox

The SyncBox is a configurable module that is responsible for scheduling all embedded hardware module within IVA-HD subsystem. It handles all aspects of synchronization, data sharing, and parameters passing between accelerators. It also offers the possibilities to use asynchronous messages.

### 6.1.2.1.2 iCONTs

The iCONT module is an ARM968E-S™ based microcontroller with 32KB of instruction tightly coupled memory and 16KB of data tightly coupled memory. It includes an interrupt controller (INTC), a local data mover, its own SyncBox module for synchronizing tasks with other modules and its associated SyncBox handler.

Two identical instances of iCONT, iCONT1, and iCONT2, are present in the IVA-HD subsystem. They can typically be used to perform high-level processing (at frame and slice level), control at macroblock-level bounding box computation and other vDMA processing tasks.

Software can map process equally on either iCONT.

### 6.1.2.1.3 vDMA

The vDMA is a DMA engine to perform data transfer between external memories and shared L2 memory and also memory copies inside SL2 and inside external memory.

### 6.1.2.1.4 iME3

The iME3 accelerator is used to perform motion estimation in encode processing. iME3 embeds its own SyncBox module for synchronizing tasks with other modules.

It compares a current macroblock to reference area and provides area in reference region (in terms of offsets) which is least different to the current macroblock. It can also interpolate a block with half or quarter pixel precision, thus producing 4 (half pixel) or 16 (quarter pixel) interpolated blocks from the original block. Additionally, it supports searching of the best matching block within the interpolated planes.

#### 6.1.2.1.5 *iPE3*

The iPE3 accelerator is used to perform the intraprediction estimation in encode. The iPE3 embeds its own SyncBox module for synchronizing tasks with other modules and an LSE to transfer data from internal memories to shared L2 memory.

It supports two modes, depending on video standard:

- Spatial intraprediction estimation for H.264 and AVS. It creates intraprediction macroblocks with given intramodes from original macroblock and provides cost estimation between the original macroblock and each pseudo intraprediction macroblock, and then chooses a mode with the smallest cost to recommend it as an optimal intraprediction mode.
- Spatial activity for MPEG-1/2/4 and VC-1. It calculates the spatial activity of the original luminance samples with the specified block size. This mode intends to provide information of the original Luma pixels. The values can be used to decide the coding parameters of the macroblock such as the coding mode and the quantization parameter.

#### 6.1.2.1.6 *MC3*

The MC3 accelerator is used to perform the motion compensation. MC3 embeds its own SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It creates an interprediction macroblock with given motion vectors and modes from the reference data.

#### 6.1.2.1.7 *CALC3*

The CALC3 accelerator is used to perform forward and inverse transform and quantization calculation. CALC3 embeds its own SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It can perform transform/inverse transform, Q/iQ and DC/AC prediction.

#### 6.1.2.1.8 *iLF3*

The iLF3 accelerator is used to perform deblocking filtering and boundary strength computation. The iLF3 embeds its own SyncBox module for synchronizing tasks with other HWAs.

#### 6.1.2.1.9 *ECD3*

The ECD3 accelerator is designed to encode and decode the stream. ECD3 embeds its own SyncBox module for synchronizing tasks with other HWAs and an LSE to transfer data from internal memories to shared L2 memory.

It supports Huffman codes and arithmetic codes.

For encode, the ECD3 encodes the macroblock information and residual data into bitstream. For decode, the ECD3 decodes the bitstream and recovers the macroblock information and residual data.

#### 6.1.2.1.10 *SL2 Interface*

The shared L2 interface, SL2IF, is an arbitrator that allows 18 initiators to access to an interleaved set of eight memory banks.

The SL2IF has two sets of interfaces:

- Eighteen 128-bit interfaces for accesses from module's to shared L2 memories.
- Eight 128-bit memory interfaces for direct accesses to memory bank

### 6.1.2.1.11 Message Bus

The message bus, is an arbitrator that allows eight initiators to access eight targets. It is used to dispatch messages generated by the SyncBox of the different IPs.

### 6.1.2.1.12 IVA-HD Local Interconnect

The IVA-HD local interconnect provides connectivity between two external host interconnects (DSP and L3), two local sequencers (iCONT1 and iCONT2) and video hardware accelerators (iME3, iLF3, ECD3, CALC3, MC3, iPE3), video DMA engine (vDMA), and local modules (mailbox and sysctrl).

### 6.1.2.1.13 MailBox

The function of the mailbox is to support a 2-way communication between two hosts through interrupt. It allows the software to establish a communication channel between processors through a set of registers and associated interrupt signals by sending and receiving messages.

The mailbox embedded inside the IVA-HD subsystem implements a 2-way communication between three external users and one internal user. This communication is ensured through three pairs of mailboxes and four-message FIFO depth for each message queue.

---

**NOTE:** The internal user is one of the two iCONTs. iCONT1 and iCONT2 are connected on a shared interrupt line. The choice between iCONT1 and iCONT2 is done by masking mailbox interrupt on iCONT1 or iCONT2. iCONT1 and iCONT2 can access the mailbox through the IVA-HD local interconnect.

---

For a detailed description of the mailbox, including IVA-HD mailbox interrupt mapping, see , *IVA-HD Imaging Controller*.

### 6.1.2.1.14 IVA-HD System Control

The SYSCTRL module of IVA-HD is in charge of:

- Controlling clocks to module's, upon software control and power handshaking state
- Controlling power, reset, and clock management (PRCM) module power handshaking
- Providing status of the above operation
- Supporting synchronization through external event

## 6.1.2.2 IVA-HD Power Management

Table 6-4 describes power-management features available for the IVA-HD module.

---

**NOTE:** For descriptions of IdleMode and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

---

**Table 6-4. Local Power-Management Features**

Feature	Registers	Description
Slave idle modes	<a href="#">IVAHD_SYSCONFIG</a> [3:2] IDLEMODE	No-idle and smart-idle modes are available.
Master standby modes	<a href="#">IVAHD_SYSCONFIG</a> [5:4] STANDBYMODE	No-standby and smart-standby modes are available.

### 6.1.2.3 IVA-HD Memory Mapping

ARM968E-S (of each iCONT) can address a 4-GB memory space. The lower address range (8MB) is allocated to its level 1 (L1) memories (ITCM and DTCM). The higher address range is allocated to L2 memories. Access to L2 memories can be buffered or nonbuffered, depending on the selected address range. For more information, see the ARM968E-STM Technical Reference Manual.

In [Table 6-5](#), the address spaces of buffered regions are shown as EXT\_BUF, and the address spaces of nonbuffered regions are shown as EXT\_NBUF.

**Table 6-5. iCONT Memory Mapping Regions**

Region Name	Address		Size (KB)	Description
	Start	Stop		
ITCM	0x0000 0000	0x0000 7FFF	32	ITCM memory aliased 128 times
	...	...	...	
ITCM (alias 127)	0x003F 8000	0x003F FFFF	32	
DTCM	0x0040 0000	0x0040 3FFF	16	DTCM memory aliased 256 times
	...	...	...	
DTCM (alias 255)	0x007F C000	0x007F FFFF	16	
EXT_BUF	0x0080 0000	0x008F FFFF	1024	External buffered region
	...	...	...	
EXT_BUF (alias 247)	0x0FF0 0000	0x0FFF FFFF	1024	External buffered region
EXT_NBUF (alias)	0x1000 0000	0x100F 0000	1024	External nonbuffered region
	...	...	...	
EXT_NBUF (alias)	0x1FF0 00000	0x1FFF FFFF	1024	External nonbuffered region
	...	...	...	
EXT_BUF (alias)	0xM000 0000	0xM0FF FFFF	1024	External buffered region
	...	...	...	
EXT_NBUF (alias)	0xFFFF 0000	0xFFFF FFFF	1024	External nonbuffered region

Each of these regions (EXT\_BUF and EXT\_NBUF) has the same memory map, aliased throughout the address range of the region. [Table 6-6](#) lists iCONT1 memory mapping, and [Table 6-7](#) lists iCONT2 memory mapping. Offsets shown are from the start of the region.

1. iCONT2 private access to its own registers
2. iCONT2 self-access to its own registers

---

**NOTE:** Definition of iCONT self-access and private access:

- Self-access: Direct access of iCONT to its own memory-mapped registers (MMRs) (reduced latency); that is, without using the IVA-HD local interconnect. Internal iCONT configuration (CFG) registers are not visible. Only IRQ, DM, and SBH registers can be accessed.
  - Private access: Access through IVA-HD local interconnect. By default, all iCONT accesses described in [Table 6-6](#) and [Table 6-7](#) are private, except for corresponding self-access. In case of iCONT private access to its own registers, internal iCONT CFG registers are visible (on top of IRQ, DM, and SBH).
- 

**NOTE:** Examples of start address:

- Buffered region: 0x0080 0000, 0x0090 0000, 0x00A0 0000, 0x0FF0 0000, 0x2000 0000, etc.
  - Nonbuffered region: 0x1000 0000, 0x1010 0000, 0x1020 0000, 0x1FF0 0000, 0x3000 0000, etc.
- 

[Table 6-8](#) shows IVA-HD modules and memory addresses for the DSP processor and L3 access.

### 6.1.3 IVA-HD Register Manual

#### CAUTION

This section provides information about iCONT memory mapping (private access). This information represents only the address offsets from the start of relevant buffered (EXT\_BUF) or nonbuffered (EXT\_NBUF) regions. For more information, see [Section 6.1.2.3, IVA-HD Memory Mapping](#).

### 6.1.3.1 IVA-HD Instance Summary

Table 6-9 shows the IVA-HD instance summary.

**Table 6-9. IVA-HD Instance Summary**

Module Name	Base Address (L3 Interconnect)	Base Address (DSP Private Access)	Base Address (iCONT Private Access)	Size
SYSCTRL	0x5A05 A400	0x01E5 A400	0x000D A400	1KB

**NOTE:** Private access is an access through the IVA-HD local interconnect without using the L3 interconnect.

### 6.1.3.2 SYSCTRL Registers

#### 6.1.3.2.1 SYSCTRL Register Summary

Table 6-10 lists the mapping summary for the SYSCTRL registers.

**CAUTION**

SYSCTRL registers are limited to 32-bit access; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

**Table 6-10. SYSCTRL Registers Mapping Summary**

## Dual Cortex-M3 MPU Subsystem

---

---

---

This chapter describes the dual Cortex-M3 microprocessor unit (MPU) subsystem.

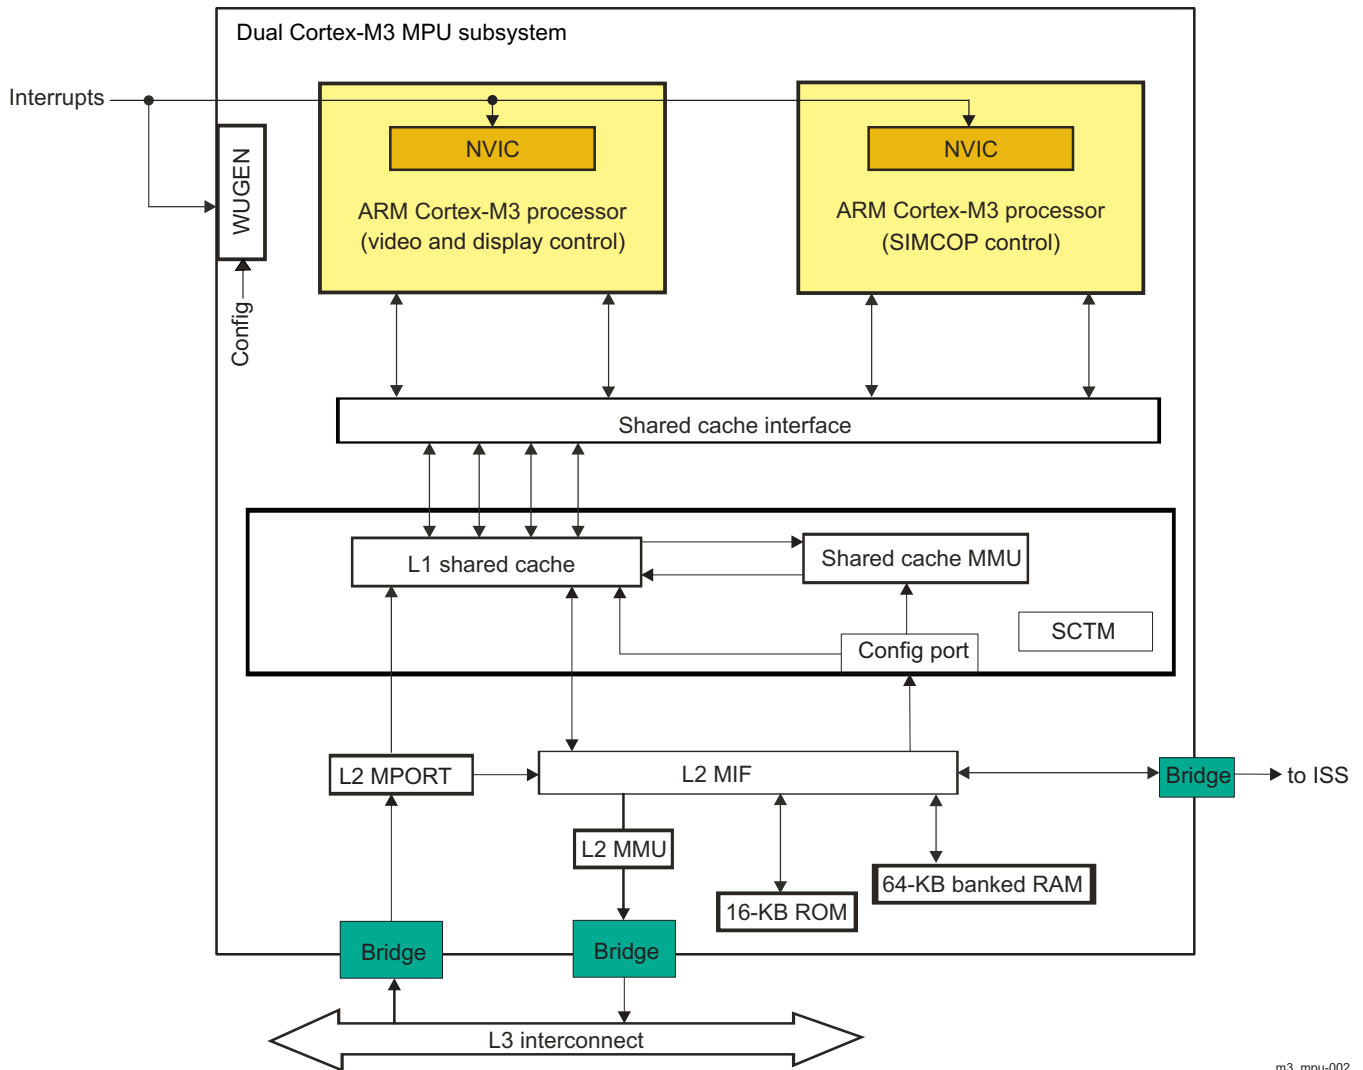

Topic	Page
7.1 Dual Cortex-M3 MPU Subsystem Overview .....	1499
7.2 Dual Cortex-M3 MPU Subsystem Integration .....	1501
7.3 Dual Cortex-M3 MPU Subsystem Functional Description .....	1505
7.4 Dual Cortex-M3 MPU Subsystem Register Manual .....	1515

## 7.1 Dual Cortex-M3 MPU Subsystem Overview

### 7.1.1 Introduction

The dual Cortex™-M3 microprocessor (MPU) subsystem controls the imaging subsystem (ISS) and manages some controls of the video and display subsystem. It contains two ARM® Cortex-M3 processors (CPUs) that share a common level 1 (L1) cache (shared cache). One of the CPUs is dedicated to sequencing still image coprocessor (SIMCOP) accelerators, and the other CPU is dedicated to the ISS and display subsystem control. A single image real-time operating system (RTOS) runs on both cores, thereby minimizing the code size. The integrated interrupt handling of the dual Cortex-M3 MPU allows efficient control of the ISS. [Figure 7-1](#) is a high-level block diagram of the dual Cortex-M3 MPU subsystem.

**Figure 7-1. Dual Cortex-M3 MPU Subsystem Overview**

m3\_mpu-002

### 7.1.2 Features

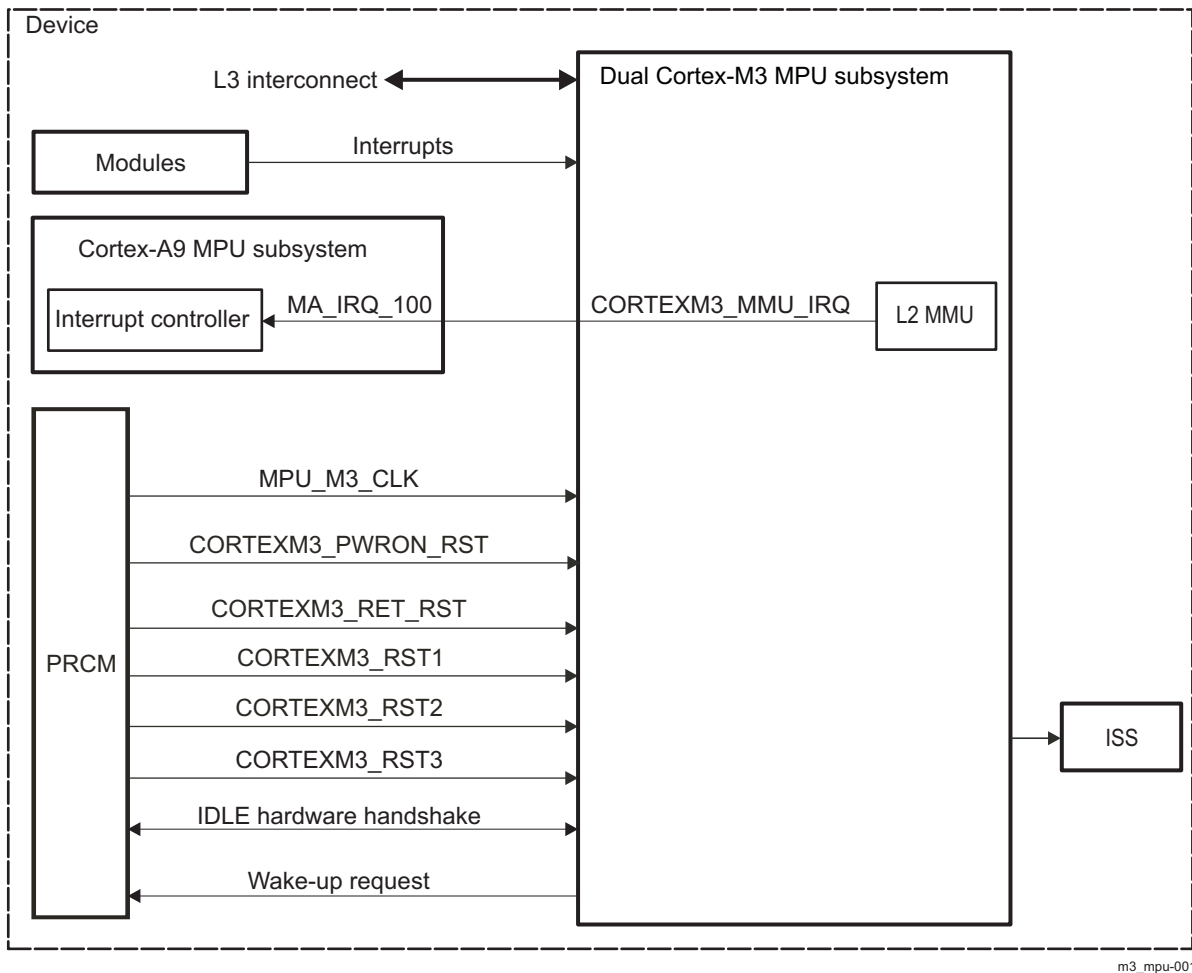

The dual Cortex-M3 MPU subsystem integrates the following:

- Two ARM Cortex-M3 microprocessors:
  - ARMv7-M and Thumb®-2 instruction set architecture
  - Hardware division and single-cycle multiplication computational acceleration
  - Integrated nested vector interrupt controller (NVIC)
  - Integrated bus matrix
  - Registers:
    - Thirteen general-purpose 32-bit registers
    - Link register (LR)
    - Program counter (PC)
    - Program status register, xPSR
    - Two banked SP registers
  - Integrated power management
  - Extensive debug capabilities
- Shared cache interface:
  - Instruction and data interface
  - Supports paralleled accesses
- Level 2 (L2) MIF (master interface) splitter for access to memory or configuration port
- Configuration port: Used for shared cache maintenance and shared cache memory management unit (MMU) configuration
- Shared cache:
  - 32KB divided into 16 banks
  - 4-way
  - Cache configuration lock/freeze/preload
  - Internal MMU:
    - 16-entry region-based address translation
    - Read/write control and access type control
    - Execute Never (XN) MMU protection policy
    - Little-endian format
- Subsystem counter timer module (SCTM)
- On-chip ROM and banked RAM memory
- Emulation/debug: Emulation feature embedded in Cortex-M3
- L2 MMU: 32 entries with walking table logic
- Wake-up generator (WUGEN): Generates wake-up request from external interrupts
- Power management:
  - Local power-management control: Configurable through the WUGEN registers.
  - Three sleep modes supported, controlled by the local power-management module.
  - Dual Cortex-M3 MPU is clock-gated in all sleep modes.
  - NVIC interrupt interface stays awake.

## 7.2 Dual Cortex-M3 MPU Subsystem Integration

Figure 7-2 shows the signals that interface with other modules.

Figure 7-2. Dual Cortex-M3 MPU Subsystem Integration Overview

**NOTE:** Some debug, trace, and emulation features are implemented in the MPU subsystem. This chapter includes only the clock/reset inputs and power-management aspects for these features.

Table 7-1 through Table 7-3 summarize the integration of the module in the device.

Table 7-1. Integration Attributes

Module Instance	Attributes	
	Power Domain	Interconnect
CORTEXM3	PD_CORE	L3

Table 7-2. Hardware Requests

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
L2_MMU	CORTEXM3_MMU_IRQ	MA_IRQ_100	Cortex-A9 MPU INTC	L2 MMU fault interrupt

**Table 7-3. Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CORTEXM3	MPU_M3_CLK	MPU_M3_CLK	PRCM module	Interface and functional clock
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
CORTEXM3	CORTEXM3_PWRON_RST	CORTEXM3_PWRON_RST	PRCM module	Power-on reset, used to reset the whole dual Cortex-M3 subsystem
	CORTEXM3_RET_RST	CORTEXM3_RET_RST	PRCM module	Retention reset to few retention logic inside the shared cache
	CORTEXM3_RST1	CORTEXM3_RST1	PRCM module	Reset signal to the video and display control CPU
	CORTEXM3_RST2	CORTEXM3_RST2	PRCM module	Reset signal to the SIMCOP CPU
	CORTEXM3_RST3	CORTEXM3_RST3	PRCM module	Reset signal to the shared cache and the L2 MMU

For more information about clocks, resets, and power domains, see [Chapter 3, Power, Reset, and Clock Management](#).

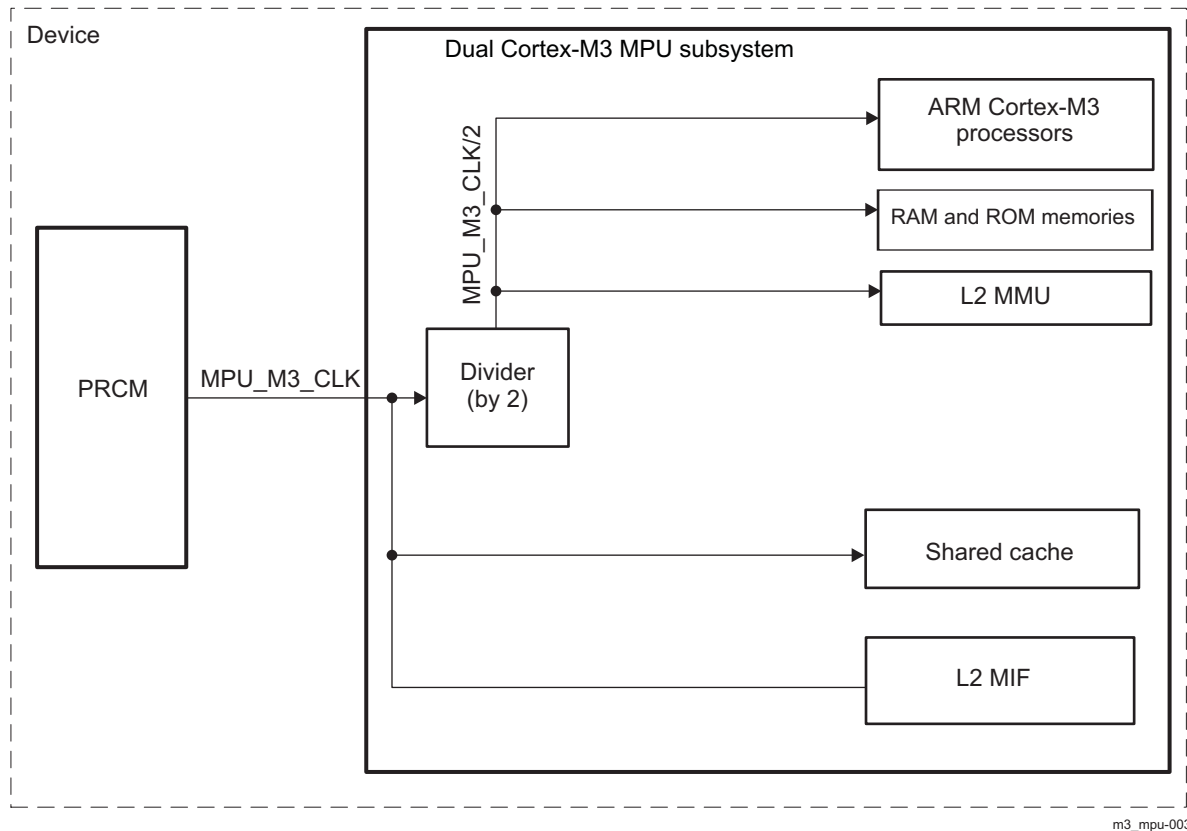

## 7.2.1 Dual Cortex-M3 MPU Subsystem Clock and Reset Distribution

### 7.2.1.1 Clock Distribution

The dual Cortex-M3 subsystem receives only one clock, MPU\_M3\_CLK, which is divided in two for each ARM Cortex-M3 processor, ROM and RAM memory and the L2 MMU. The shared cache and the L2 MIF are directly clocked by the MPU\_M3\_CLK, without any division. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

[Figure 7-3](#) shows the clocking scheme of the MPU subsystem.

Figure 7-3. Dual Cortex-M3 MPU Subsystem Clocking Scheme

m3\_mpu-003

### 7.2.1.2 Reset Distribution

Three reset signals controlled by the power, reset, and clock management (PRCM) module let the two ARM Cortex-M3 processors and the rest of the dual Cortex-M3 MPU subsystem be reset independently. These three reset signals are: CORTEXM3\_RST1, CORTEXM3\_RST2, and CORTEXM3\_RST3. The ARM Cortex-M3 processors must come out of reset one at a time:

- At CORTEXM3\_RST1, the video and display control ARM Cortex-M3 processor comes out of reset, but the SIMCOP ARM Cortex-M3 processor is held in reset.
- The video and display control ARM Cortex-M3 controls the reset for the SIMCOP Cortex-M3 (through the PRCM register - RM\_MPU\_M3\_RSTCTRL[1] RST2).

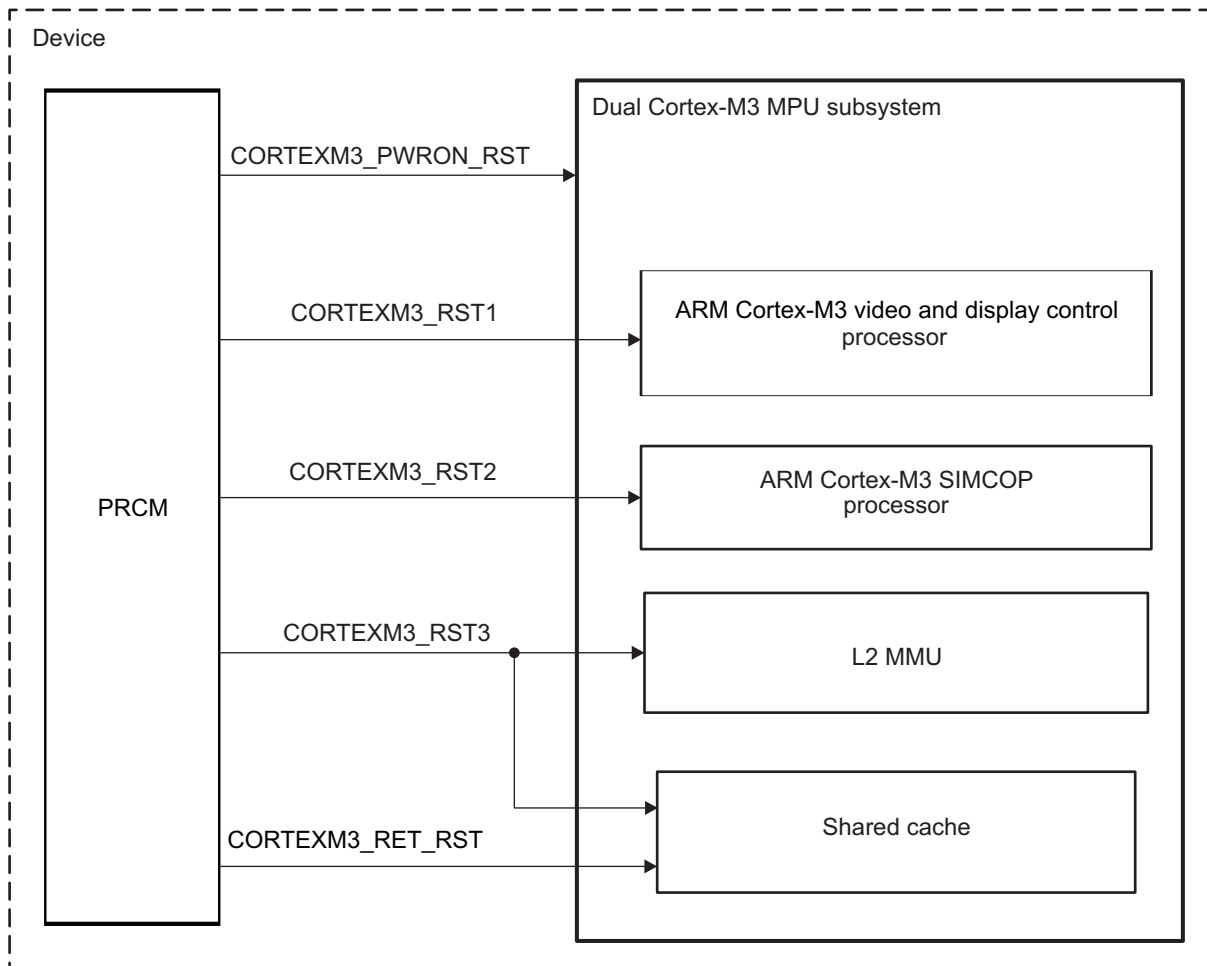

As the video and display control ARM Cortex-M3 controls the reset for the SIMCOP Cortex-M3 (through the PRCM registers), the code running on the video and display control ARM Cortex-M3 decides the mode of operation, whether it is:

- Mode 1: One ARM Cortex-M3 processor is running, and the other processor is held on reset.
- Mode 2: The two ARM Cortex-M3 processors are running.

This decision of which mode to use is driven by the use case. If the software partitioning and performance requirement for a use case requires two Cortex-M3 processor to run simultaneously, the user must go to mode 2. If SIMCOP Cortex-M3 is not required for a particular use case, the user can remain in mode 1.

Figure 7-4 shows the reset scheme of the MPU subsystem.

**Figure 7-4. Dual Cortex-M3 MPU Subsystem Reset Scheme**

m3\_mpu-004

## 7.3 Dual Cortex-M3 MPU Subsystem Functional Description

### 7.3.1 Dual Cortex-M3 MPU Subsystem Block Diagram

The dual Cortex-M3 MPU subsystem integrates the following group of submodules:

- Two ARM Cortex-M3 processors: Two cores (r2p0 revision), one dedicated to sequencing SIMCOP accelerators and the other dedicated for video and display subsystem control. For a description of the ARM Cortex-M3 processor, see the *ARM Cortex-M3 Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).
- Interrupt controller (NVIC): To facilitate parallel processing, the interrupt mapping is the same for the two cores. Each Cortex-M3 processor receives the same interrupts, except for a few internal interrupts. Every IRQ line is shared between the two ARM processors. By properly configuring the NVIC registers inside each ARM processor, it can be ensured that the shared IRQ is taken by only one of the ARM processors (for more information, see [Chapter 17, Interrupt Controller](#)).
- Shared cache interface: The cache interface converts the data between the different protocols in the subsystem. Four ports are required to support the four buses from the ARM Cortex-M3 processors (two for each processor). The instruction and data connections from each ARM Cortex-M3 are multiplexed, but the ARM Cortex-M3 prevents conflicts on this connection. Default cache policies are provided through the sideband signals and are not used to access the cache. Cacheability is provided through the MMU inside the cache.
- Shared cache: Allows basic maintenance operations, which are performed through a dedicated interface: preload, lock, clean (write out dirty lines, but do not invalidate directly), and invalidate.
- Shared cache MMU: Provides the multiple access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. Access to the shared cache MMU is done only under privilege mode. The shared cache MMU can be programmed by the Cortex-A9 MPU subsystem through the Cortex-M3 slave port.
- SCTM: Embedded in the shared cache
- Interconnect configuration port: Cache maintenance and MMU configuration are done through an interconnect slave port. Accesses must be performed to a noncacheable area that must be defined within the shared cache MMU. Interconnect accesses are generated from the L2 MIF.
- L2 MMU: Provides address translation for all the accesses done from the Cortex-M3 to the level 3 (L3) interconnect. The L2 MMU can be programmed by the Cortex-A9 MPU subsystem through the Cortex-M3 slave port.
- L3 interconnect port: Allows access to the system memories and peripherals. For the address mapping of the modules in the dual Cortex-M3 MPU subsystem, see [Chapter 2, Memory Mapping](#).
- On-chip ROM and banked RAM memory. The ROM memory is used for boot/initialization purposes. For more information about the initialization of the device, see [Chapter 27, Initialization](#). The address range of the ROM memory is from 0x5500\_0000 to 0x5500\_3FFF. The address range of the on-chip banked RAM memory is from 0x5502\_0000 to 0x5502\_FFFF.

[Figure 7-5](#) is the block diagram of the dual Cortex-M3 MPU subsystem.

**Figure 7-5. Dual Cortex-M3 MPU Block Diagram**

### 7.3.2 Power Management

**NOTE:** For information about source clock gating and for a description of the sleep/wake-up transitions, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

### 7.3.2.1 Local Power Management

The user can configure the local power management through the [STANDBY\\_CORE\\_SYSCONFIG](#), [IDLE\\_CORE\\_SYSCONFIG](#), and [WUGEN\\_IRQ\\_EN](#) registers. The user can:

- Configure the different standby modes (the default is smart wake-up standby mode) through the [STANDBY\\_CORE\\_SYSCONFIG\[1:0\]](#) STANDBYMODE bit field
- Configure the different idle modes (the default is smart wake-up idle mode) through the [IDLE\\_CORE\\_SYSCONFIG\[1:0\]](#) IDLEMODE bit field
- Control which interrupts will cause a wakeup by appropriately configuring the [WUGEN\\_MEVT0](#) and [WUGEN\\_MEVT1](#) registers (the default is ALL\_MASKED)

The Cortex-M3 provides three sleep modes:

- On mode: Sleep on exit (wait for the interrupt service routine [ISR] to complete)
- Sleep mode: Wait for interrupt to wake up the processor
- Deep-sleep mode: Long duration sleep; phase-locked loop (PLL) can be stopped

During sleep mode, the system clock can be stopped, but the free-running clock input must still be running to allow the processor to be wakened by an interrupt or an event. The sleep modes are invoked by wait for interrupt (WFI) or wait for event (WFE) instructions. The processor clock is automatically stopped, waiting for an interrupt or an event. Deep-sleep mode also stops the processor clock, but this can also be supported by the PRCM module. A combined signal is generated from the two Cortex-M3 processors in deep-sleep mode to initiate another power state and let the PRCM module handle the next power states. At this time, software must ensure that all shared cache background operations (for example, maintenance) are complete.

[Table 7-4](#) describes local clock gating.

**Table 7-4. Local Clock Gating**

Cortex-M3 CPU Mode	CPU2 On	CPU2 Sleep	CPU2 Deep Sleep
<b>CPU1 On</b>	On	Functional clock 2 stopped locally	Functional clock 2 stopped locally
<b>CPU1 Sleep</b>	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Functional clock 1 and clock 2 stopped locally
<b>CPU1 Deep Sleep</b>	Functional clock 1 stopped locally	Functional clock 1 and clock 2 stopped locally	Standby request to power-management module

### 7.3.2.2 Power Domains

The dual Cortex-M3 MPU subsystem is divided into two power domains (CORE and WKUP), which are controlled by the PRCM module (see [Section 7.3.2.3](#)).

The CORE power domain is the main power domain and includes all the Cortex-M3 components (two ARM Cortex-M3 processors, shared cache, ROM and RAM memories, and emulation\debug modules) except the WUGEN.

The AWLON\_CORE power domain is an always-on power domain. The AWLON\_CORE power domain contains the WUGEN, which generates a wake-up request from external interrupts. By this separate AWLON\_CORE power domain, the wake-up request can be generated even when the CORE power domain is in OFF or RET state.

For information about the CORE and ALWON\_CORE power domains, see [Chapter 3, Power, Reset, and Clock Management](#).

### 7.3.2.3 Voltage Domain

The dual Cortex-M3 MPU subsystem is composed of two voltage domains. Each voltage domain can control individual voltage levels:

- VDD1: Cortex-M3, shared cache/MMU, WUGEN
- VDD\_array: All memories array

The AWLON\_CORE and CORE power domains are in the same voltage domain – the CORE voltage domain (CORE\_VD).

For information about the physical power domains, see [Chapter 3, Power, Reset, and Clock Management](#).

### 7.3.2.4 Power States and Modes

[Table 7-5](#) lists the different power modes and the expected states for each power domain.

**Table 7-5. Dual Cortex-M3 MPU Power Modes**

	Functional Domain	Activity			Power Status	
		Core		Dual Cortex-M3 MPU Subsystem	CORE Power Domain	AWLON_CORE Power Domain
	Modules included	Cortex-M3 processor 1	Cortex-M3 processor 2	WUGEN		
Power modes	Active	Active	Active	Active	ON	ON
	Processor 1 idle	Idle	Active	Active	ON	ON
	Processor 2 idle	Active	Idle	Active	ON	ON
	Core standby	Idle	Idle	Active	ON	ON
	Full idle	Idle	Idle	Idle	ON	ON
	Retention	Idle	Idle	Idle	RET	ON
	Power off	Idle	Idle	Idle	OFF	OFF

[Table 7-6](#) lists the power mode transitions in the dual Cortex-M3 MPU subsystem.

**Table 7-6. Power Mode Transitions**

	Active	Processor 1 Idle	Processor 2 Idle	Standby	Full-Idle	Retention	Power Off
Active		WFE/WFI instruction	WFE/WFI instruction				
Processor 1 idle	Events/interrupts			Deep sleep			
Processor 2 idle	Events/interrupts			Deep sleep			
Standby	Wake-up IRQ				L1/L2/WUGEN functional domain idle		
Full idle	Wake-up IRQ			Wake-up (through interconnect)		PRCM module	PRCM module
Retention					PRCM module or wakeup		PRCM module
Power off					PRCM module or wakeup	PRCM module	

The different power modes and their features are:

- Active mode: All function domains are operable.
- Core 1 and Core 2 idle mode:
  - Only the CPU core is idled (when running WFE/WFI instructions).
  - Only one Cortex-M3 core can be in this mode. Interrupts or events can waken the core.
  - Can go into sleep or deep-sleep mode. Potentially, both cores can be in sleep mode.
  - When both cores are in deep-sleep mode, a standby request is sent to the PRCM module.
  - Software must ensure that all shared cache background operations (for example, maintenance) are complete before the PRCM module asserts an IdleReq. For more information, see [Chapter 5, DSP, Section 5.4.2.2.3.1, Direct Maintenance of Caches](#).

- Core standby mode
  - Both cores in the CORE functional domain are in idle mode (an interrupt cannot wake up either of the cores).
  - The PRCM module must have acknowledged its acceptance by an MWait signal.
  - After this handshake, all power management is under the control of the PRCM module.
- Full-idle mode:
  - The dual Cortex-M3 MPU subsystem functional domain is also idled.
  - After coming to this mode, power states can be moved deeper.
- Retention mode:
  - The voltage of the logic supply is lowered to reduce static power consumption by leakage current. The logic power switch in the CORE power domain is still closed (ON); thus, all logic states are retained.
  - L1 and/or L2 memories can go independently into retention depending on the settings done at the PRCM level.
- Power off mode:
  - The voltage source is shut down. The logic states, including the retention logic, are lost.
  - The WUGEN is not operating and only the PRCM module can trigger the Cortex-M3 wakeup.
  - Reset must be applied to the dual Cortex-M3 MPU subsystem to restart the two ARM Cortex-M3 processors and the memory subsystem.

### 7.3.2.5 Wake-Up Generator

The WUGEN in the dual Cortex-M3 MPU subsystem enables efficient power management. The WUGEN generates a wake-up signal to the PRCM module to enable the dual Cortex-M3 MPU subsystem to recover its functional clocks, which are gated by the PRCM module when at least one request is active. The WUGEN can be configured in standby mode or idle mode through the [STANDBY\\_CORE\\_SYSCONFIG\[1:0\] STANDBYMODE](#) and [IDLE\\_CORE\\_SYSCONFIG\[1:0\] IDLEMODE](#) bit fields.

#### 7.3.2.5.1 WUGEN Main Features

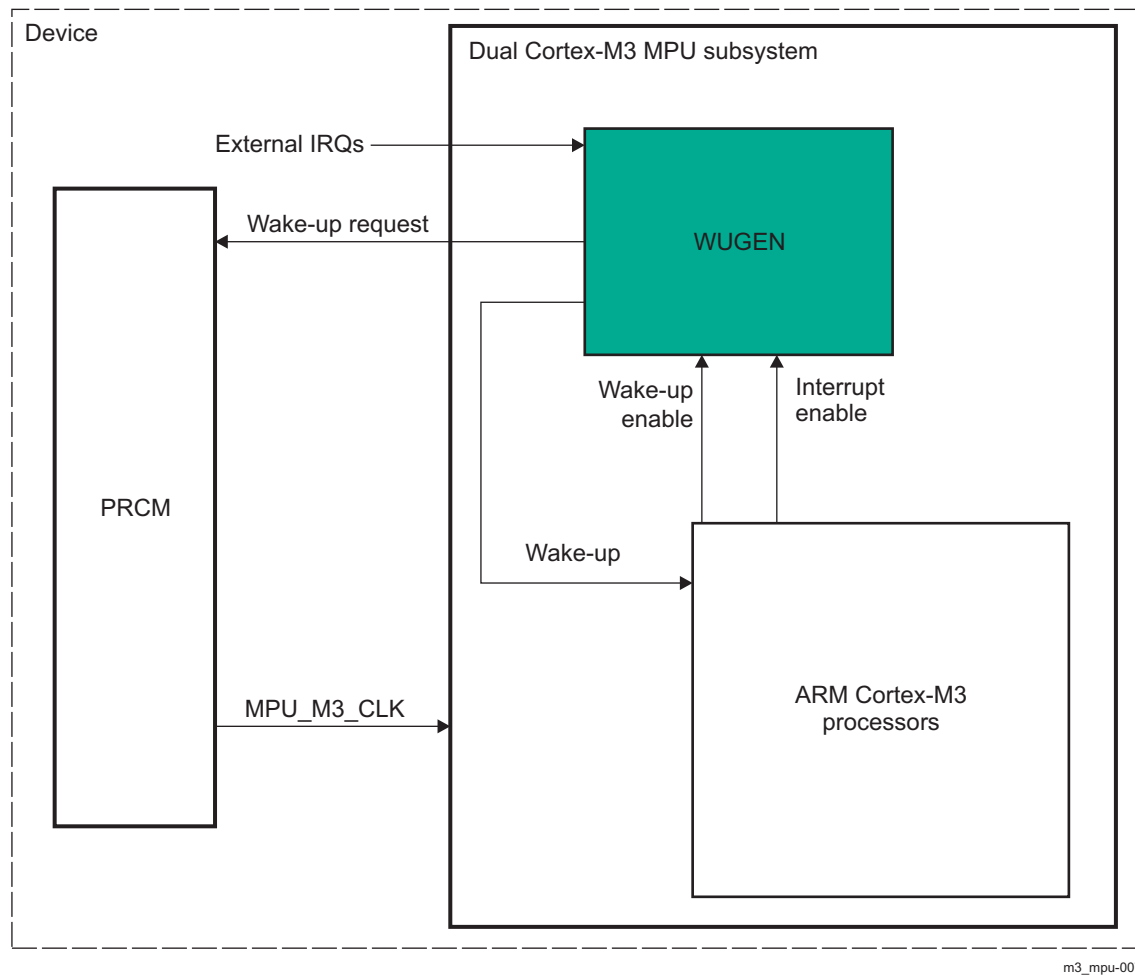

The WUGEN allows:

- Gating of the Cortex-M3 MPU clock dynamically, thus reducing power consumption
- Simplifying of dependencies in the PRCM module

[Figure 7-6](#) is an overview of the WUGEN.

Figure 7-6. WUGEN Overview

m3\_mpu-007

The wake-up signal to the PRCM module requests the Cortex-M3 functional clock (MPU\_M3\_CLK). The wake-up signal to the ARM Cortex-M3 processors indicates to them that at least one enabled request is active.

Two retention registers [WUGEN\\_MEVT0](#) (for CPU1) and [WUGEN\\_MEVT1](#) (for CPU2), enable the WUGEN requests to the NVICs.

### 7.3.3 Shared Cache

[Table 7-7](#) describes the shared cache configuration in the dual Cortex-M3 MPU subsystem platform.

**Table 7-7. Shared Cache Configuration**

Parameter	Value
Way	4
Size	32KB
Bank elements	32 bits
Bank number	16
Slave interface data size	32 bits
Master interface data size	64 bits
Line size	256 bits
MMU lookup	Included
Number of slaves	4

**Table 7-7. Shared Cache Configuration (continued)**

Parameter	Value
Number of masters	1
Number of fill/prefetch buffers	Four prefetch buffers
Slave types	Shared cache interface

Shared cache allows basic maintenance operations, which are performed through a dedicated interface:

1. Preload
2. Lock
3. Clean
4. Invalidate

Maintenance of the cache is performed between the start and end addresses. This allows for direct control of memory regions. All maintenance operations occur in the background and can generate an interrupt when they complete. Such operations are protected by software semaphore, because only one operation at a time can be performed. The maintenance operations can also be performed using MMU small entries.

The shared cache is the same as the one in the DSP subsystem. For more information about the shared cache, see [Chapter 5, DSP Subsystem](#).

### 7.3.4 Shared Cache MMU

The MMU for the shared cache provides the multi-access cache with region-based address translation, read/write control, access type control, and multilevel cache maintenance. [Table 7-8](#) describes the MMU configuration in the dual Cortex-M3 MPU subsystem.

**Table 7-8. Shared Cache MMU Configuration**

Parameter	Values
Number of large pages	Four entries
Size of large pages	512MB or 32MB (configurable)
Number of medium pages	Two entries
Size of medium pages	256KB or 128MB (configurable)
Number of small pages	10 entries
Size of small pages	16KB or 4KB (configurable)
Number of patch pages	Not included
Size of line pages	256-bit
Number of comparison interfaces	4
Number of comparator sets	1
Write pipeline data comparison	Disabled
Number of shared cache maintenance interfaces	3
Size of entry address	32-bit

The size of the pages is configurable in the shared cache MMU registers. The different MMU page sizes can be used to create smaller policies within a larger region. The shared cache MMU is the same as the one in the DSP subsystem. For more information, see [Chapter 5, DSP Subsystem](#).

### 7.3.5 L2 MMU

An additional MMU provides address translation for the accesses done from the dual Cortex-M3 MPU subsystem to the L3 interconnect. The main characteristics of this MMU are:

- 32 entries
- Compatible with ARMv6 architecture MMU translation tables (protection bits not used)
- Page-based or access-based endianness conversion

- Two-level descriptor hierarchy
- One intermediate page table
- Four page sizes (16MB, 1MB, 64KB, 4KB)
- Page table alignment on 128-byte boundary for ARM11® compatibility

The configuration of the MMU can be done from one of the Cortex-M3 cores or from the L3 interconnect slave port. The accesses done to configure the MMU cannot be part of a burst access.

For more information about the L2 MMU, see [Chapter 20, Memory Management Unit](#).

### 7.3.5.1 L2 MMU Behavior on Page-Fault in Dual Cortex-M3 MPU

**Table 7-9. L2 MMU Behavior on Page-Fault**

Application		Debug	
Table-Walker Enabled	Table-Walker Disabled	Table-Walker Enabled	Table-Walker Disabled
Use Table-Walker to find translation. Update TLB cache if successful, set TRANSLATIONFAULT bit and interrupt if not. The following bits are used for the purpose: MMU_IRQENABLE[1] TRANSLATIONFAULT and MMU_IRQSTATUS[1] TRANSLATIONFAULT.	Set TLBMISS bit and interrupt and stall. The following registers are used for the purpose: MMU_IRQENABLE[0] TLBMISS and MMU_IRQSTATUS[0] TLBMISS.	Use Table-Walker to find translation. Update TLB cache if successful (only if MMU_CNTL[3] EMUTLBUPDATE is set), generate in-band bus error if not.	Set EMUMISS bit and interrupt and stall. The following bits are used for the purpose: MMU_IRQENABLE[2] EMUMISS and MMU_IRQSTATUS[2] EMUMISS.

The MMU fault interrupt line is connected to both Cortex-M3 cores and also propagated outside of Cortex-M3 and connected to the Cortex-A9 MPU (MA\_IRQ\_100). The Cortex-A9 MPU receives the MMU fault and must clean up the fault to resume the execution of the code (or reset Cortex-M3). It is not possible for one of the Cortex-M3 CPUs to clean up the fault caused by the other Cortex-M3 CPU. This is because both the slave port of L2 MMU (which is stalled) and the configuration port of L2 MMU is connected (through a splitter) to the same shared cache master port.

The above default behavior of the L2 MMU can be overridden by setting the MMU\_GP\_REG[0] BUS\_ERR\_BACK\_EN bit to 1. Once this bit is set, all MMU faults (including TLB miss) return a bus error to the Cortex-M3 (interrupt event XLATE\_MMU\_FAULT). This allows the end user to quickly establish the cause of the MMU fault by having appropriate code in the ISR.

## 7.3.6 Interprocessor Communication (IPC)

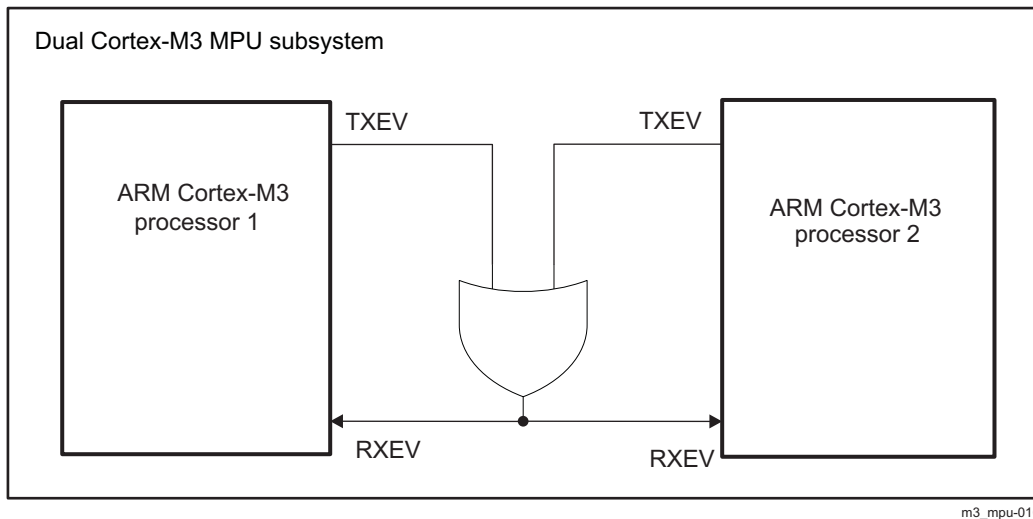

### 7.3.6.1 Use of WFE and SEV

The dual Cortex-M3 MPU subsystem provides multiprocessor communication interface for synchronizing tasks. The ARM processors have one output signal, TXEV (transmit event), for sending events and one input signal, RXEV (receive event), for receiving events. [Figure 7-7](#) shows how TXEV and RXEV are connected in the dual Cortex-M3 MPU subsystem.

When a WFE instruction is executed, the processor enters into sleep mode waiting for an event and continues instruction execution when an external event is received. With an SEV (send event) instruction, one processor can wake up the other processor, which is in sleep mode.

The WFE and SEV instructions can help reduce the number of iterations around a lock acquire loop (a spinlock), and thereby reduce power consumption. The basic mechanism involves an observer that is in a spinlock executing a WFE instruction, which suspends execution on that observer until an asynchronous exception or an explicit event (sent by an observer using the SEV instruction) is seen by that observer. The observer that holds the lock uses the SEV instruction to send an event after a lock is released.

**Figure 7-7. Event Communication Connection in Dual Cortex-M3 MPU Subsystem**

### 7.3.6.2 Use of Interrupt for IPC

Each Cortex-M3 can interrupt the other Cortex-M3 by setting up an interrupt register ([CORTEXM3\\_CTRL\\_REG](#)). Because the priority level for that interrupt can be defined, it is possible to choose the task level at which the interrupt will run. For example, if CPU1 was active and CPU2 was idle (WFI state), when CPU1 completes its task it sets the bit for CPU2 in the control register ([CORTEXM3\\_CTRL\\_REG\[16\] INT\\_CORTEX\\_2](#)) and goes into sleep mode. CPU2 wakes up seeing this interrupt, and starts running its task. After the completion of its task, CPU2 sets the interrupt for CPU1 ([CORTEXM3\\_CTRL\\_REG\[0\] INT\\_CORTEX\\_1](#)), and then goes into WFI state. This kind of handshake ensures that if CPU1 and CPU2 are accessing the same resources (memory, registers etc.), only one of the CPUs at a time is active.

### 7.3.6.3 Use of the Bit-Band Feature for Semaphore Operations

The two Cortex-M3 cores share the same memory system, and it is possible to use the bit-band feature to carry semaphore operations. Because the bit-band alias writes are locked read-modify-write transfers, provided that all tasks changed only the lock bit representing themselves, the lock bits of other tasks are not lost, even if two tasks try to write to the same memory location at the same time.

Each Cortex-M3 core supports two bit-band regions.

Bit-band 1 applies to the virtual address space 0x2000 0000 – 0x200F FFFF (1MB). This virtual address space can be mapped to any physical address and bit-banding will apply to that region. It is recommended that the user map the L2 RAM (64KB) to this virtual space and use it only for bit-banding operations. If required, the user can define other available small and medium pages over and above the L2 RAM virtual space and further extend the use of the bit-band feature.

Bit-band 2 applies to the virtual address space 0x4000 0000 – 0x400F FFFF (1MB). The first 16KB of this space (0x4000 0000 – 0x4000 3FFF) are already reserved for small (one page) pages and cannot be remapped by software. The bit-band alias that corresponds to this 16-KB region (0x4200 0000 – 0x4207 FFFF) must also be treated as reserved and no access should be made. The rest of bit-band 2 can be used by appropriately defining the available small and medium pages. In this device, because it is likely that during normal AMMU programming all of L3 is mapped to this region, it is highly recommended that the user use only bit-band 1 for all purposes and bit-band 2 only if it is necessary.

#### 7.3.6.4 Private Memory Space

Each ARM Cortex-M3 processor has its own memory space, unaccessible by the other processor. In the private memory space are the NVICs and RW table registers: [CORTEXM3\\_RW\\_PID1](#) and [CORTEXM3\\_RW\\_PID2](#). [CORTEXM3\\_RW\\_PID1](#) and [CORTEXM3\\_RW\\_PID2](#) are only accessible by the respective Cortex-M3 cores ([CORTEXM3\\_RW\\_PID1](#) is accessible only to the video and display control ARM processor, while [CORTEXM3\\_RW\\_PID2](#) is only accessible by the SIMCOP processor) . These registers are not accessible from the Cortex-A9 MPU. Because they are not shared, they do not require bit-band feature (semaphore) to read and write to them.

## 7.4 Dual Cortex-M3 MPU Subsystem Register Manual

### 7.4.1 Dual Cortex-M3 Subsystem Instance Summary

Table 7-10 summarizes the dual Cortex-M3 MPU instance.

**Table 7-10. Dual Cortex-M3 MPU Subsystem Instance Summary**

Module Name	Base Address	Size
SCACHE_CFG	0x5508 0000	4KB
SCACHE_SCTM	0x5508 0400	4KB
SCACHE_MMU	0x5508 0800	4KB
CORTEXM3_WKUP	0x5508 1000	4KB
CORTEXM3_MMU	0x5508 2000	4KB
CM3_NVIC_CPU1 <sup>(1)</sup>	0xE000 E000	4KB
CM3_NVIC_CPU2 <sup>(2)</sup>	0xE000 E000	4KB
CM3_RW_Table <sup>(3)</sup>	0xE00F E000	4KB

<sup>(1)</sup> Private memory space for CPU1

<sup>(2)</sup> Private memory space for CPU2

<sup>(3)</sup> Private memory space for each CPU

### 7.4.2 Shared Cache Configuration Registers

For information about the shared cache configuration registers and their description, see [Chapter 5, DSP Subsystem](#).

### 7.4.3 Shared Cache SCTM Registers

For information about the shared cache SCTM registers and their description, see [Chapter 5, DSP Subsystem](#).

The SCTM registers in the Cortex-M3 MPU differ from the registers listed in [Chapter 5, DSP Subsystem](#), in the following ways:

- Counters with indexes from  $i = 2$  to 5 can be chained and shadowing is enabled.
- The reset value of the SCACHE\_SCTM\_CTCR\_WOT\_j[7] CHNSDW bit is 1.
- The option to write 1 in the SCACHE\_SCTM\_CTCR\_WOT\_j[4] CHAIN bit is not reserved and when the bit is write 1, the counter is chained.

### 7.4.4 Shared Cache MMU Registers

For information about the shared cache MMU registers and their description, see [Chapter 5, DSP Subsystem](#).

The shared cache MMU in Cortex-M3 has four large pages, two medium pages, and ten small pages. Because of the different page sizes, there are differences with the registers described in [Chapter 5, DSP Subsystem](#), in the enumerated indexes below the register mapping, which are the following: ( $i = 0$  to 3), ( $j = 0$  to 1), ( $k = 0$  to 9). There are also differences in the reset value of the following registers:

- SCACHE\_MMU\_SMALL\_ADDR\_0 with reset value 0x00000000
- SCACHE\_MMU\_SMALL\_ADDR\_1 with reset value 0x40000000
- SCACHE\_MMU\_SMALL\_POLICY\_k with reset value 0x00000000 ( $k = 0$  to 9)
- SCACHE\_MMU\_SMALL\_XLTE\_0 with reset value 0x55020000
- SCACHE\_MMU\_SMALL\_XLTE\_1 with reset value 0x55080000
- SCACHE\_MMU\_SMALL\_XLTE\_k with reset value 0x00000000 ( $k = 2$  to 9)

The page sizes for the 16 entries are:

- Large pages (four): The page size supported are 32MB and 512MB.

- Medium pages (two): The page sizes supported are 128KB and 256KB.
- Small pages (ten): The page sizes supported are 4KB and 16KB.

### 7.4.5 Cortex-M3 L2 MMU Registers

For information about the L2 MMU registers and their description, see [Chapter 20, Memory Management Unit](#).

### 7.4.6 Cortex-M3 NVIC Registers

For information about the Cortex-M3 MPU NVIC registers and their description, see the *ARM Cortex-M3 Technical Reference Manual* (available at [infocenter.arm.com/help/index.jsp](http://infocenter.arm.com/help/index.jsp)).

### 7.4.7 Cortex-M3 Wake-Up Generator Registers

#### 7.4.7.1 CORTEXM3\_WKUP Register Summary

[Table 7-11](#) summarizes the dual Cortex-M3 MPU register mapping.

**Table 7-11. CORTEXM3\_WKUP Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	Cortex-M3 Base Address

## Imaging Subsystem

---

---

---

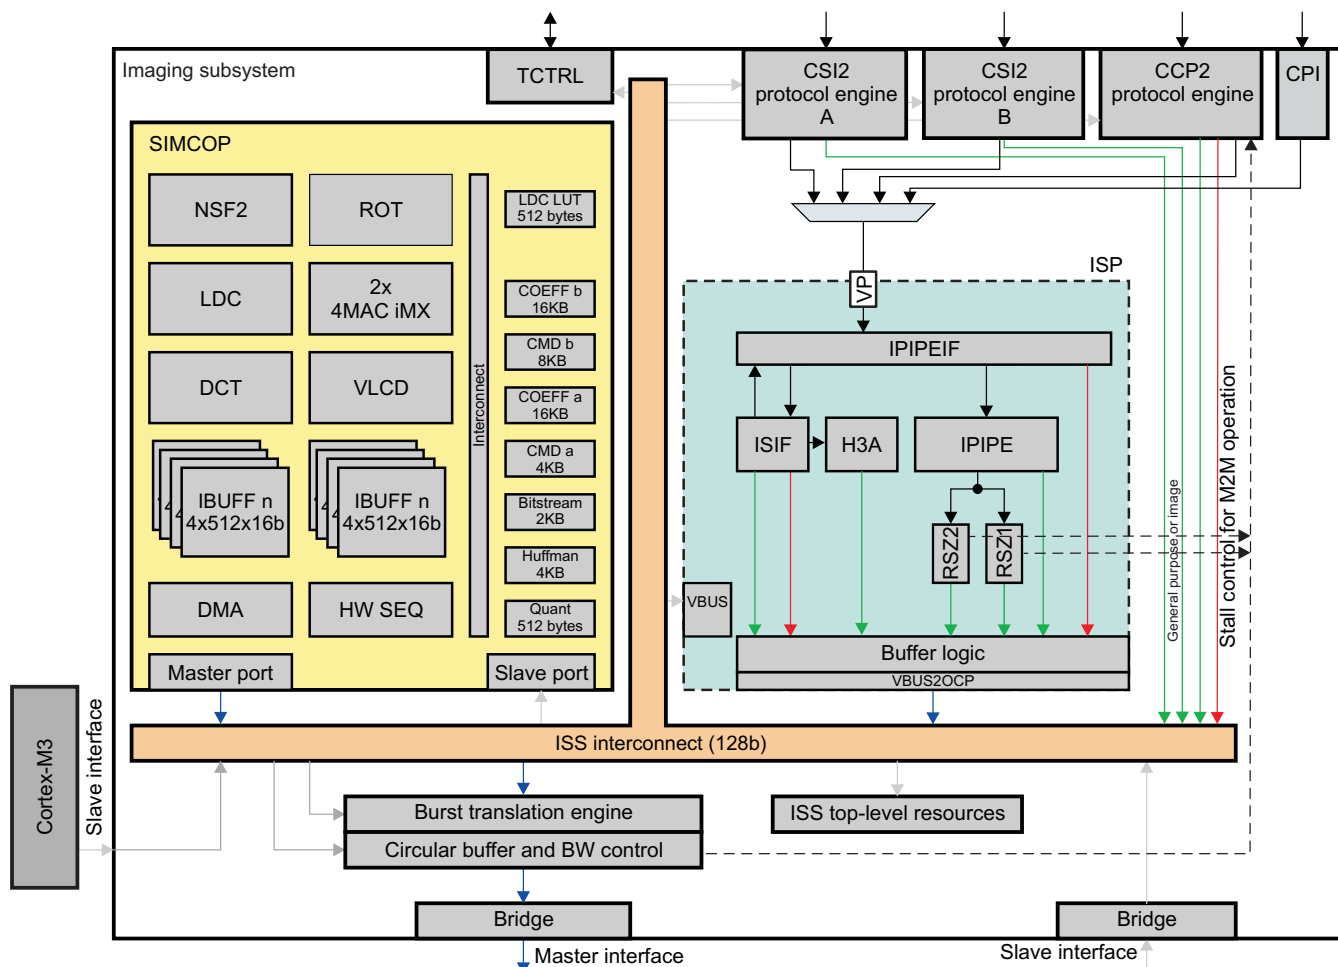

This chapter gives a top-level overview of the imaging subsystem (ISS) in the device.

Topic	Page
8.1 ISS Overview .....	1523
8.2 ISS Interfaces .....	1560
8.3 ISS ISP .....	1829
8.4 ISS Still Image Coprocessor .....	2288

### 8.1 ISS Overview

The imaging subsystem (ISS) deals with the processing of the pixel data coming from an external image sensor, data from memory (image format encoding and decoding can be done to and from memory), or data from SL2 in IVA-HD for hardware encoding. With its subparts, such as interfaces and interconnects, image signal processor (ISP), and still image coprocessor (SIMCOP), the ISS is a key component for the following multimedia applications: camera viewfinder, video record, and still image capture. [Figure 8-1](#) shows an overview of the ISS.

**Figure 8-1. ISS Overview**

camss-351

The direction of the arrows shows the command flow direction from the master (initiator) to the slave (target). The following color conventions are used for the connections:

- Blue: Bidirectional, 128-bit-wide interface data connection
- Green: Write (ISS → system memory) data connection. Either 64-bit interface, 128-bit interface, or 32-bit MTC (inside ISP5).
- Red: Read (system memory to ISS) data connection. 128-bit interface port or 32-bit MTC (inside ISP5).
- Gray: 32-bit interface configuration connection
- Solid black: Video port and camera interface related signals
- Dotted black: Data flow stall control signal. Used to slow down ISP for memory-to-memory operation.

The ISS is mainly composed of CCP2 and CSI2-A, CSI2-B camera interfaces, a parallel interface (CPI), an ISP, and a block-based imaging accelerator (SIMCOP).

The ISS is designed to reach high throughput and low latency with large image sensors. In high-performance mode, the ISS supports a pixel throughput of 200 MPix/s.

Two programmable image processors (iMX4) are included in the SIMCOP subsystem to add further flexibility to implement new algorithms or where new issues are encountered with the image sensors. The iMX4 processors are also open to third-party algorithms.

The ISS is tightly coupled with a low-interrupt latency microprocessor unit (MPU) subsystem (Cortex™-M3 MPU) that runs a real-time operating system (OS) to reach optimal performance. Mainly, the Cortex-M3 MPU can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks.

The ISS targets the following major use cases:

- Viewfinder with digital zoom, video stabilization, and rotations
- Up to 1080p video record at 30 fps with digital zoom, video stabilization, and rotation
- Up to 16 MPix still image capture with digital zoom and rotation
  - High performance mode: Up to 200 MPix/s throughput
  - High quality and low light modes: Up to 50 MPix/s throughput
- Still image capture during video record

---

**NOTE:** The ISS is not limited to 16 Mpix. Higher resolution can be achieved through multiple passes.

---

---

**NOTE:** For a detailed list of features of a certain submodule, see the related subsection.

---

The ISS offers the following features:

- SIMCOP:
  - Memory-to-memory operation
  - JPEG encode and decode hardware acceleration
  - High-ISO noise filtering (NSF 2.0) with up to 120 MPix/s throughput
  - Rotation accelerator
  - Warping accelerator
  - Lens distortion correction (YUV space) with up to 200 MPix/s throughput
  - General-purpose (GP) imaging accelerator (2x iMX4) with up to 400-MHz clock speed
  - Direct memory access (DMA) controller
  - Hardware sequencer
- ISP:
  - On-the-fly or memory-to-memory processing
  - Up to 200-MHz pixel throughput
  - Statistic data collection
  - Image pipe interface front-end raw data processing
  - RGB and YUV data processing through ISIF and IPIPE
  - Hardware 3A (H3A) statistics block for real-time auto focus (AF), auto exposure (AE), and auto white balance (AWB)
  - Two image continuous real-time resizers
  - Video port (VP) for interfacing with the receivers and directing data to the ISP
- ISS interfaces:
  - 128-bit-wide data interface to the level 3 (L3) interconnect
  - Burst translation engine (BTE) tightly coupled with the TILER to support efficient rotation
  - Circular buffer for linear space, physically located in memory

- The ISS relies on the centralized memory management unit (MMU) feature of the DMM. See [Chapter 20, Memory Management Unit](#), and [Chapter 15, Memory Subsystem](#).
- Two CSI2 camera interfaces: CSI2-A (primary) and CSI2-B (secondary)
- CCP2 camera interface (secondary). Compatible with the *SMIA CCP2 Specification v1.0* and the *MIPI CSI1 Specification*.
- Parallel interface (CPI) (16 bit wide, with up to 148.5 MPix/s throughput, and supporting BT656, SYNC modes)
- System memory data read-back port (supported by the CCP2 protocol engine module)

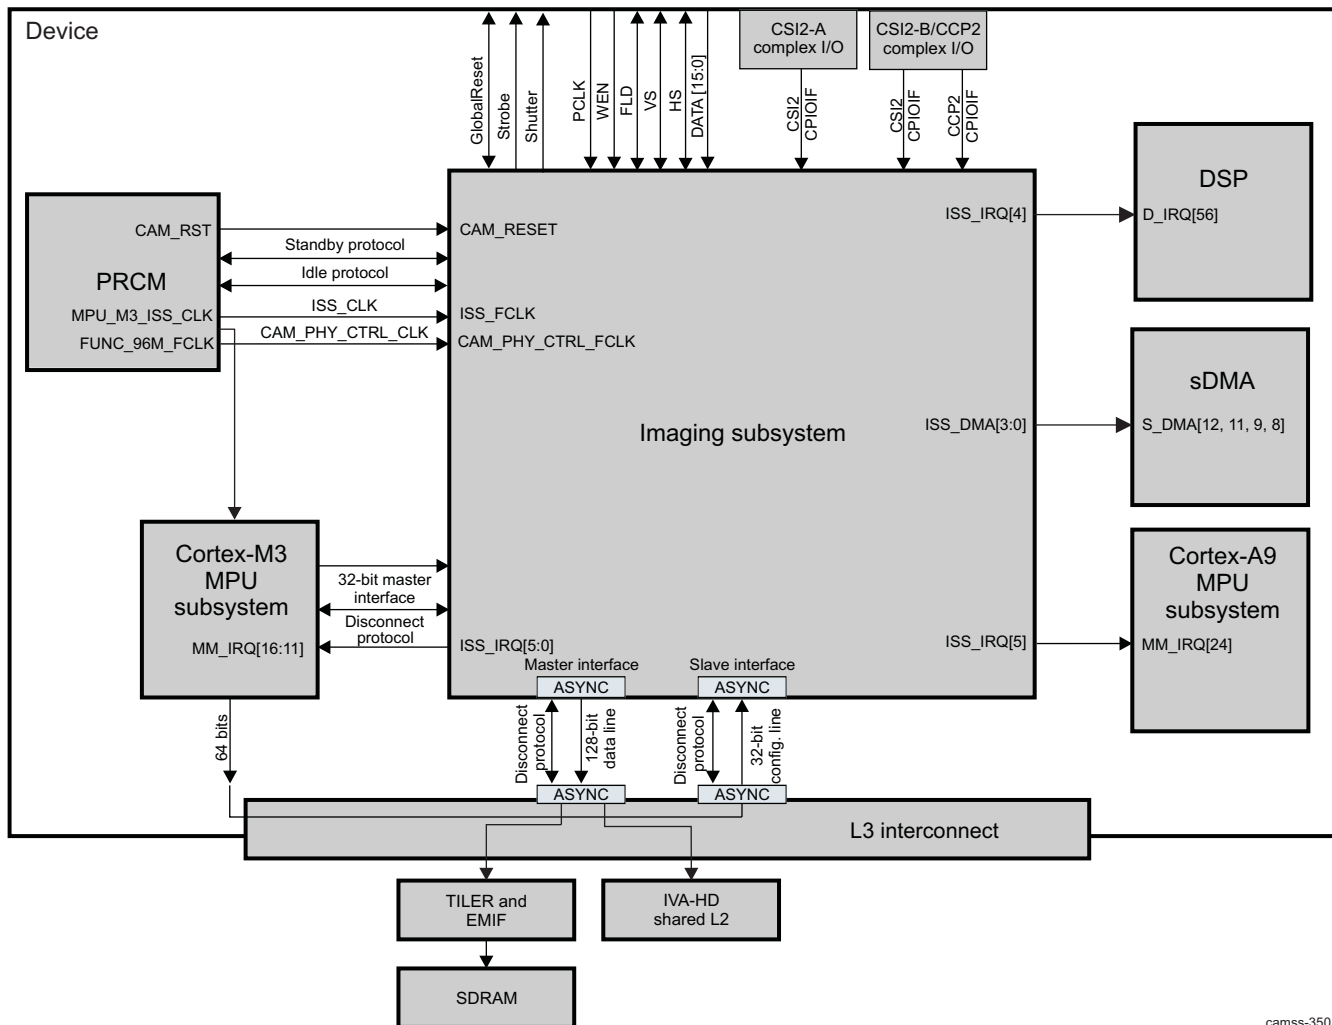

### 8.1.1 ISS Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 8-2 shows the ISS integration.

**Figure 8-2. ISS Integration**

camss-350

**NOTE:** For more information about the IDLE hardware handshake and wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

This section gives an overview of typical uses of the module. For more information about the relationship of the power, reset, and clock management (PRCM) module to the ISS clocks and the reset settings, see the detailed functional description in [Chapter 3, Power, Reset, and Clock Management](#).

The ISS is part of ISS hardware and power management, which comprises the Cortex-M3 MPU, ISS, and a clock generator. These are all independent power domains. The ISS is part of the CAM power domain.

The PRCM module provides a single clock (**MPU\_M3\_ISS\_CLK**) to ISS power management. This clock generates the clocks for the Cortex-M3 MPU, ISS, and the bridges to L3.

The ISS also supports software reset. A software reset has the same function as a hardware reset except that it does not reset the power-management protocols.

When enabled, MPU\_M3\_ISS\_CLK is gated to provide ISS\_CLK, which, after entering the ISS boundary, is named ISS\_FCLK. MPU\_M3\_ISS\_CLK is provided as long as the Cortex-M3 MPU or ISS modules within the ISS require it.

CAM\_PHY\_CTRL\_CLK is gated from FUNC\_96M\_FCLK, which comes from the PRCM module. When enabled and inside the ISS boundary, it is called CAM\_PHY\_CTRL\_FCLK.

**NOTE:** For more information about the device clocks and how they are handled by the PRCM module before going into the ISS, see, *CM2 Clock Generator*, in [Chapter 3, Power, Reset, and Clock Management](#).

Table 8-1 through Table 8-3 summarize the integration of the module in the device.

**Table 8-1. ISS Integration Attributes**

Module Instance	Attributes		
	Power Domain	Wake-Up Capability	Interconnect
ISS	PD_CAM	No	

**Table 8-2. ISS Clocks and Resets**

Clocks				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ISS	ISS_FLCK	ISS_CLK	PRCM	ISS global functional clock from the PRCM module
	CAM_PHY_CTRL_FCLK	CAM_PHY_CTRL_CLK	PRCM	Physical layer functional clock from the PRCM module
Resets				
Module Instance	Destination Signal Name	Source Signal Name	Source	Description
ISS	CAM_RESET	CAM_RST	PRCM	ISS global reset

**Table 8-3. ISS Hardware Requests**

Interrupt Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
ISS	ISS_IRQ4	D_IRQ_56	DSP INTC	Interrupt generated by ISS to DSP
	ISS_IRQ5	MM_IRQ_24	Cortex-A9 INTC	Interrupt generated by ISS to Cortex-A9
	ISS_IRQ0	MM_IRQ_11	Cortex-M3 INTC	Interrupt generated by ISS to Cortex-M3
	ISS_IRQ1	MM_IRQ_12	Cortex-M3 INTC	Interrupt generated by ISS to Cortex-M3
	ISS_IRQ2	MM_IRQ_13	Cortex-M3 INTC	Interrupt generated by ISS to Cortex-M3
	ISS_IRQ3	MM_IRQ_14	Cortex-M3 INTC	Interrupt generated by ISS to Cortex-M3
	ISS_IRQ4	MM_IRQ_15	Cortex-M3 INTC	Interrupt generated by ISS to Cortex-M3
	ISS_IRQ5	MM_IRQ_16	Cortex-M3 INTC	Interrupt generated by ISS to Cortex-M3
DMA Requests				
Module Instance	Source Signal Name	Destination Signal Name	Destination	Description
ISS	ISS_DMA0	S_DMA_8	sDMA	Signal connected to the sDMA directly provided by ISP.
	ISS_DMA1	S_DMA_9	sDMA	Signal connected to the sDMA directly provided by ISP
	ISS_DMA2	S_DMA_11	sDMA	Signal connected to the sDMA directly provided by ISP
	ISS_DMA3	S_DMA_12	sDMA	Signal connected to the sDMA directly provided by ISP

### 8.1.1.1 ISS PRCM Interface Integration

#### 8.1.1.1.1 ISS Clock Domains

The ISS has five asynchronous clock domains. Most of the logic uses ISS\_FCLK; the other clock domains are used for interfaces.

[Table 8-4](#) provides a high-level view of clocks. The frequencies provided are maximum values.

**Table 8-4. ISS Local Clock Domains**

Name	Description
PCLK	Parallel interface (CPI) pixel clock provided by the camera external sensor. The CSI2-A, CSI2-B, and CCP2 modules also have video port outputs, each having its own pixel clock. These pixel clocks are generated from the functional clock (ISS_FCLK). Then all four pixel clock sources are multiplexed into one clock provided to the ISP.
CSI2_A_BC	Byte clock provided by the CSI2-A complex I/O. Used by the CSI2-A receiver.
CSI2_B_BC	Byte clock provided by the CSI2-B/CCP2 complex I/O. Used by the CSI2-B receiver.
CCP2_BC	Clock provided by the CCP2 complex I/O. Used by the CCP2 protocol engine.
ISS_FCLK	Functional clock provided by ISS_CLK from the PRCM module. It is used by all ISS submodules and ISS top-level resources.
CAM_PHY_CTRL_FCLK	Functional clock provided by the PRCM module. It is used by the CSI2-A and CSI2-B/CCP2 complex I/Os.

To save power, the ISS can divide the received functional clock (ISS\_CLK) by 2 or 4 from [ISS\\_CTRL\[4:5\]](#) ISS\_CLK\_DIV. The configuration clock is always half the functional clock.

The functional clock of some submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the [ISS\\_CLKCTRL](#) register. Also, the pixel clocks sent by submodules to ISP can be cut off from [ISS\\_CLKCTRL](#) VPORT<sub>x</sub>\_CLK.

## 8.1.2 ISS Functional Description

This section provides only a top-level overview of the ISS. The ISS submodules are described in: [Section 8.4, ISS:SIMCOP](#), [Section 8.2, ISS:interfaces](#), and [Section 8.3, ISS:ISP](#).

[Section 8.1.2.1, ISS Interrupts](#), describes the ISS power-management mechanisms and gives an introduction to and a functional description of the ISP submodules.

### 8.1.2.1 ISS Interrupts

[Table 8-5](#) lists the events generated by the submodules and the top level of the ISS.

Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the [ISS\\_HL\\_IRQENABLE\\_SET\\_i](#) register. The interrupt is disabled by setting the appropriate bit in the [ISS\\_HL\\_IRQENABLE\\_CLR\\_i](#) register.

When an event occurs, the corresponding bit in the [ISS\\_HL\\_IRQSTATUS\\_RAW\\_i](#) register is set regardless of whether or not the event is enabled. Bits in the [ISS\\_HL\\_IRQSTATUS\\_i](#) registers are set only when an enabled event occurs.

Software can clear a pending HS\_VS\_IRQ event by setting the [ISS\\_HL\\_IRQSTATUS\\_i\[17\]](#) HS\_VS\_IRQ bit. Events generated by submodules are automatically cleared at the ISS level when they are cleared at the submodule level.

#### 8.1.2.1.1 ISS Interrupt Merger

The ISS merges the following eight interrupt sources into six physical interrupt lines. All six lines support level and pulse modes.

**Table 8-5. ISS Interrupts**

Interrupt	Source	Description
ISP_IRQ[3:0]	ISP	Interrupt generated by the ISP <sup>(1)</sup>
CSIA_IRQ	CSI2-A	Interrupt generated by the CSI2-A receiver <sup>(1)</sup>
CSIB_IRQ	CSI2-B	Interrupt generated by the CSI2-B receiver <sup>(1)</sup>
CCP2_IRQ[3:0]	CCP2	Interrupt generated by the CCP2 receiver <sup>(1)</sup>
CCP2_IRQ[8]	CCP2	Interrupt generated by the CCP2 receiver <sup>(1)</sup>
CBUFF_IRQ	CBUFF	Interrupt generated by the circular buffer <sup>(1)</sup>
BTE_IRQ	BTE	Interrupt generated by the BTE <sup>(1)</sup>
SIMCOP_IRQ[3:0]	SIMCOP	Interrupt generated by SIMCOP
HS_VS_IRQ	ISS	HS or VS synchronization event. This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen using the ISP_CTRL[0:1] SYNC_DETECT bit field.

<sup>(1)</sup> For more information, see [Section 8.1.2.1.2, ISS Submodule Interrupts](#).

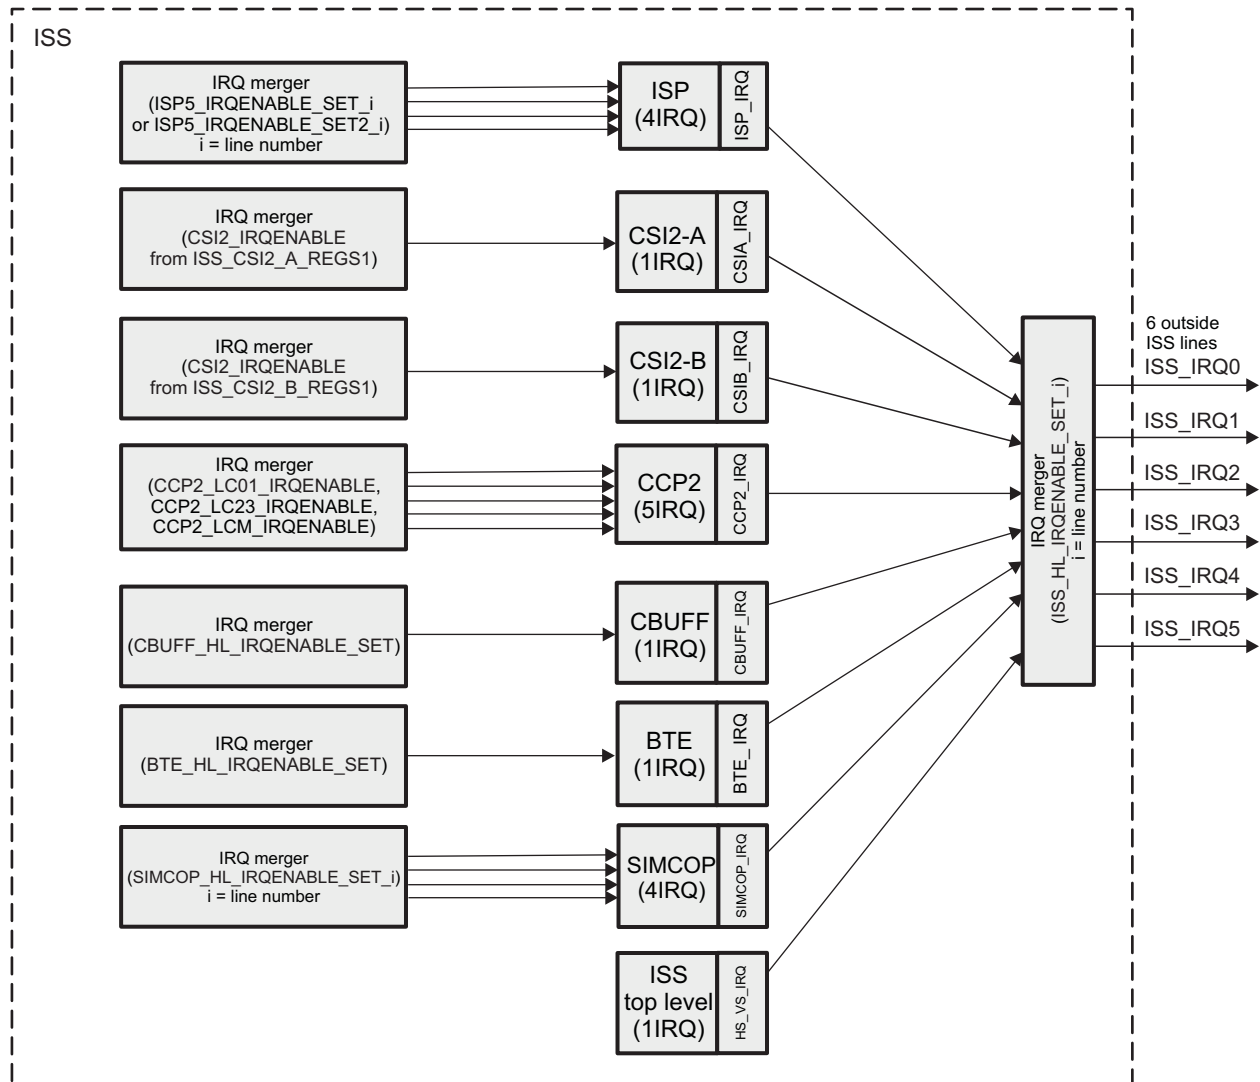

Software can select which interrupt sources are routed to each output line (ISS\_IRQ[0:5]). All six physical interrupt outputs have equivalent functions. Software can use different interrupt lines to group events together by type and therefore reduce interrupt latencies. Typically, one interrupt line is used for low-priority events (errors), and the other interrupt lines are used for high-priority events (for example, SIMCOP sequencing and end-of-frame events to trigger configuration load). The ISS internal interrupt request (IRQ) merger (see [Figure 8-3](#)) relies only on level interrupts provided by submodules. Pulse interrupts provided by submodules are ignored. Typically, all of the interrupts are routed to the Cortex-M3 running the camera driver. In addition, one interrupt is routed to Cortex-A9, which may run the imaging software. Software does not need to clear events from submodules at the ISS level: it clears only the events at the submodule level; the IRQ merger automatically clears the IRQ at this level.

---

**NOTE:** Only the HS\_VS\_IRQ top-level event is cleared at the ISS level.

---

Figure 8-3. ISS Interrupt Merger

camss-702u

**NOTE:** For more information about mapping the six lines to the outside ISS device modules, see [Table 8-3](#).

Only the ISP, SIMCOP, and HL ISS merger IRQ lines are configurable. Each interrupt can be mapped to the required line. This is not the case with CCP2 where, for example, LC01 is hardwired to line0 and line1.

### 8.1.2.1.2 ISS Submodule Interrupts

The ISS shown in [Figure 8-3](#) and listed in [Table 8-3](#) can generate six interrupts.

#### 8.1.2.1.2.1 ISS ISP Interrupts

[Table 8-6](#) summarizes events that cause ISP interrupts.

**Table 8-6. ISS ISP Interrupts**

<b>Event and Register <sup>(1)</sup></b>	<b>Description</b>
ISP5_IRQENABLE_SET_ii[[31] OCP_ERR_IRQ	An interface port error has been received on the ISP master port.
ISP5_IRQENABLE_SET_ii[[29] IPIPE_INT_DPC_RNEW1	HD interrupt signal to indicate the need to renew the defect pixel correction (DPC) table with new entries. The second 128 entries in the DPC table must be updated when this event triggers. This event is triggered when the 255th entry in the look-up table (LUT) is used. This interrupt is not synchronous to the HD signal.
ISP5_IRQENABLE_SET_ii[[28] IPIPE_INT_DPC_RNEW0	VD interrupt signal to indicate the need to renew the DPC table with new entries. The first 128 entries in the DPC table must be updated when the event triggers. This event is triggered when the 127th entry in the LUT is used. This interrupt is not synchronous to the HD signal.
ISP5_IRQENABLE_SET_ii[[27] IPIPE_INT_DPC_INI	Interrupt to signal the need to initialize the DPC table. The DPC table contains two tables of 128 entries. When this signal is used, software must ensure that the 256 table entries are updated with the DPC information.
ISP5_IRQENABLE_SET_ii[[25] IPIPE_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_ii[[24] H3A_INT_EOF	End of frame interrupt signal
ISP5_IRQENABLE_SET_ii[[22] RSZ_INT_EOF1	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[23] RSZ_INT_EOF0	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[19] RSZ_FIFO_IN_BLK_ERR	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[18] RSZ_FIFO_IN_OVF	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[17] RSZ_INT_CYC_RZB	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[16] RSZ_INT_CYC_RZA	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[15] RSZ_INT_DMA	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[14] RSZ_INT_LAST_PIX	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[13] RSZ_INT_REG	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[12] H3A_INT	Interrupt generated by the AF and AE/AWB blocks inside the H3A module. It indicates the end of processing a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_ii[[11] AF_INT	AF inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.
ISP5_IRQENABLE_SET_ii[[10] AEW_INT	AEW inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish.
ISP5_IRQENABLE_SET_ii[[9] IPIPEIF_IRQ	IPIPEIF module interrupt is generated at the start position of a frame and is active high for one configuration bus clock cycle.
ISP5_IRQENABLE_SET_ii[[8] IPIPE_INT_HST	IPIPE module interrupt is generated when histogram is done.
ISP5_IRQENABLE_SET_ii[[7] IPIPE_INT_BSC	IPIPE module interrupt is generated when boundary signal calculation is done.
ISP5_IRQENABLE_SET_ii[[6] IPIPE_INT_DMA	IPIPE module interrupt is issued when the SDRAM transfer of boxcar is done. At this time, IPIPE EOF is sent to buffer logic.
ISP5_IRQENABLE_SET_ii[[5] IPIPE_INT_LAST_PIX	IPIPE module interrupt is issued when the last pixel of a frame comes into IPIPE.
ISP5_IRQENABLE_SET_ii[[4] IPIPE_INT_REG	IPIPE module interrupt is issued when the register update of the module is allowed.
ISP5_IRQENABLE_SET_ii[[3] ISIF_INT_3	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_ii[[2] ISIF_INT_2	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .

<sup>(1)</sup> i = 0 to 3

**Table 8-6. ISS ISP Interrupts (continued)**

Event and Register <sup>(1)</sup>	Description
ISP5_IRQENABLE_SET_i[1] ISIF_INT_1	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET_i[0] ISIF_INT_0	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET2_i[0] H3A_OVF	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET2_i[1] IPIPEIF_UDF	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET2_i[2] IPIPE_BOXCAR_OVF	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET2_i[3] ISIF_OVF	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .
ISP5_IRQENABLE_SET2_i[4] IPIPE_HST_ERR	See <a href="#">Section 8.1.3, ISS Register Manual</a> , and <a href="#">Section 8.3.5, ISS ISP Register Manual</a> .

#### 8.1.2.1.2.2 ISS CSI2-A and CSI2-B Complex I/O Interrupts

[Table 8-7](#) lists the event generation of the CSI2-A and CSI2-B receivers through the CSI2 interrupt status and interrupt enable registers. The events are checked for status using the CSI2\_IRQSTATUS and CSI2\_IRQENABLE registers.

**Table 8-7. ISS CSI2-A and CSI2-B Interrupts**

Event and Register	Description
CSI2_IRQENABLE[14] OCP_ERR_IRQ	Interface port error
CSI2_IRQENABLE[13] SHORT_PACKET_IRQ	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types from 0x8 to 0xF are considered)
CSI2_IRQENABLE[12] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (short packet only).
CSI2_IRQENABLE[11] ECC_NO_CORRECTION_IRQ	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
CSI2_IRQENABLE[9] COMPLEXIO_ERR_IRQ	Error signaling from complex I/O: This interrupt is triggered when any error is received from the complex I/O (events are defined in CSI2_COMPLEXIO_IRQSTATUS [see <a href="#">Table 8-8</a> ]).
CSI2_IRQENABLE[8] FIFO_OVF_IRQ	FIFO overflow error: This interrupt is triggered when a FIFO overflow is detected. An overflow can occur if there is a mismatch between the data input and output rates. A reset of the module is required to restart correctly.
CSI2_IRQENABLE[7] CONTEXT7	At least one interrupt event enabled from Context 7 occurred (see <a href="#">Table 8-9</a> ).
CSI2_IRQENABLE[6] CONTEXT6	At least one interrupt event enabled from Context 6 occurred (see <a href="#">Table 8-9</a> ).
CSI2_IRQENABLE[5] CONTEXT5	At least one interrupt event enabled from Context 5 occurred (see <a href="#">Table 8-9</a> ).
CSI2_IRQENABLE[4] CONTEXT4	At least one interrupt event enabled from Context 4 occurred (see <a href="#">Table 8-9</a> ).
CSI2_IRQENABLE[3] CONTEXT3	At least one interrupt event enabled from Context 3 occurred (see <a href="#">Table 8-9</a> ).
CSI2_IRQENABLE[2] CONTEXT2	At least one interrupt event enabled from Context 2 occurred (see <a href="#">Table 8-9</a> ).
CSI2_IRQENABLE[1] CONTEXT1	At least one interrupt event enabled from Context 1 occurred (see <a href="#">Table 8-9</a> ).
CSI2_IRQENABLE[0] CONTEXT0	At least one interrupt event enabled from Context 0 occurred (see <a href="#">Table 8-9</a> ).

Table 8-8 lists CSI2 receiver event generation through the CSI2-A/CSI2-B complex I/O interrupt status and interrupt enable registers. The events are checked and controlled from the CSI2\_COMPLEXIO\_IRQSTATUS and CSI2\_COMPLEXIO\_IRQENABLE registers.

**Table 8-8. ISS CSI2-A and CSI2-B Receivers Complex I/O Interrupts**

Event and Register	Description
CSI2_COMPLEXIO_IRQENABLE[0] ERRSOTHS1	Start of transmission error for lane 1
CSI2_COMPLEXIO_IRQENABLE[1] ERRSOTHS2	Start of transmission error for lane 2
CSI2_COMPLEXIO_IRQENABLE[2] ERRSOTHS3	Start of transmission error for lane 3
CSI2_COMPLEXIO_IRQENABLE[5] ERRSOTSYNCHS1	Start of transmission sync error for lane 1
CSI2_COMPLEXIO_IRQENABLE[6] ERRSOTSYNCHS2	Start of transmission sync error for lane 2
CSI2_COMPLEXIO_IRQENABLE[7] ERRSOTSYNCHS3	Start of transmission sync error for lane 3
CSI2_COMPLEXIO_IRQENABLE[10] ERRESC1	Escape entry error for lane 1
CSI2_COMPLEXIO_IRQENABLE[11] ERRESC2	Escape entry error for lane 2
CSI2_COMPLEXIO_IRQENABLE[12] ERRESC3	Escape entry error for lane 3
CSI2_COMPLEXIO_IRQENABLE[15] ERRCONTROL1	Control error for lane 1
CSI2_COMPLEXIO_IRQENABLE[16] ERRCONTROL2	Control error for lane 2
CSI2_COMPLEXIO_IRQENABLE[17] ERRCONTROL3	Control error for lane 3
CSI2_COMPLEXIO_IRQENABLE[20] STATEULPM1	Lane 1 in ULPM
CSI2_COMPLEXIO_IRQENABLE[21] STATEULPM2	Lane 2 in ULPM
CSI2_COMPLEXIO_IRQENABLE[22] STATEULPM3	Lane 3 in ULPM
CSI2_COMPLEXIO_IRQENABLE[25] STATEALLULPMENTS	All active lanes are entering the ULPM.
CSI2_COMPLEXIO_IRQENABLE[26] STATEALLULPMEXIT	At least one active lane exited the ULPM.

Because the CSI2-A/CSI2-B receivers support eight contexts, the CSI2\_CTX\_IRQSTATUS<sub>i</sub> and CSI2\_CTX\_IRQENABLE<sub>i</sub> registers are present eight times (one time per context).

The events are generated only for the enabled context(s). Table 8-9 describes the generation of the CSI2 receiver event through the CSI2\_CTX\_IRQSTATUS<sub>i</sub> and CSI2\_CTX\_IRQENABLE<sub>i</sub> registers.

**Table 8-9. ISS CSI2-A/CSI2-B Receivers CONTEXT Interrupts**

Event <sup>(1)</sup>	Description
CSI2_CTX_IRQENABLE <sub>i</sub> [0] FS_IRQ	Frame start: This interrupt is triggered when a frame-start synchronization code is detected in the CSI2 data stream.
CSI2_CTX_IRQENABLE <sub>i</sub> [1] FE_IRQ	Frame end: This interrupt is triggered when a frame-end synchronization code is detected in the CSI2 data stream.
CSI2_CTX_IRQENABLE <sub>i</sub> [2] LS_IRQ	Line start: This interrupt is triggered when a line-start synchronization code is detected in the CSI2 data stream.
CSI2_CTX_IRQENABLE <sub>i</sub> [3] LE_IRQ	Line end: This interrupt is triggered when a line-end synchronization code is detected in the CSI2 data stream.
CSI2_CTX_IRQENABLE <sub>i</sub> [5] CS_IRQ	CS error: This interrupt is triggered when a mismatch between the transmitter and receiver checksums (payload) is detected.
CSI2_CTX_IRQENABLE <sub>i</sub> [6] FRAME_NUMBER_IRQ	Frame counter reached: This interrupt is triggered when the frame counter reaches its programmable target value.
CSI2_CTX_IRQENABLE <sub>i</sub> [7] LINE_NUMBER_IRQ	Line number reached: The programmable line number is received. The modulo feature can be selected (CSI2_CTX_CTRL1 <sub>i</sub> .LINE_MODULO). When selected, the interrupt is generated for each line number multiple of the programmed line number (CSI2_CTX_CTRL3 <sub>i</sub> .LINE_NUMBER); otherwise, the interrupt is generated only for the line number.
CSI2_CTX_IRQENABLE <sub>i</sub> [8] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (long packets only).

<sup>(1)</sup> i = 0 to 7

### 8.1.2.1.2.3 ISS CCP2 Interrupts

Table 8-10 summarizes the CCP2 receiver interrupts.

**Table 8-10. ISS CCP2 Receiver Interrupts**

Event and Register	Description
CCP2_LC01_IRQENABLE[31] LC1_OCPERROR_IRQ	CCP2 write master interface port error on logical channel 1
CCP2_LC01_IRQENABLE[27] LC1_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 1. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[26] LC1_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 1. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[25] LC1_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 1. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[24] LC1_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 1. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[23] LC1_COUNT_IRQ	CCP2 frame counter reached on logical channel 1. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC01_IRQENABLE[21] LC1_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 1. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC01_IRQENABLE[20] LC1_CRC_IRQ	CCP2 CRC error for logical channel 1. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected.
CCP2_LC01_IRQENABLE[19] LC1_FSP_IRQ	CCP2 false-synchronization protection code error for logical channel 1. This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bitstream.
CCP2_LC01_IRQENABLE[18] LC1_FW_IRQ	CCP2 frame-width error for logical channel 1. This interrupt is generated if the frame width constraints associated with the current data type are not respected.
CCP2_LC01_IRQENABLE[17] LC1_FSC_IRQ	CCP2 false-synchronization code error for logical channel 1. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state-machine (FSM).
CCP2_LC01_IRQENABLE[15] LC0_OCPERROR_IRQ	CCP2 write master interface port error on logical channel 1
CCP2_LC01_IRQENABLE[11] LC0_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 0. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[10] LC0_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 0. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[9] LC0_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 0. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[8] LC0_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 0. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC01_IRQENABLE[7] LC0_COUNT_IRQ	CCP2 frame counter reached on logical channel 0. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC01_IRQENABLE[5] LC0_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 0. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC01_IRQENABLE[4] LC0_CRC_IRQ	CCP2 CRC error for logical channel 0. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected.
CCP2_LC01_IRQENABLE[3] LC0_FSP_IRQ	CCP2 false-synchronization code error for logical channel 0. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC01_IRQENABLE[2] LC0_FW_IRQ	CCP2 frame-width error for logical channel 0. This interrupt is generated if the frame-width constraints associated with the current data type are not respected.

**Table 8-10. ISS CCP2 Receiver Interrupts (continued)**

<b>Event and Register</b>	<b>Description</b>
CCP2_LC01_IRQENABLE[1] LC0_FSC_IRQ	CCP2 false-synchronization code error for logical channel 0. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[31] LC3_OCPERROR_IRQ	CCP2 write master interface port error on logical channel 3
CCP2_LC23_IRQENABLE[27] LC3_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 3. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[26] LC3_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 3. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[25] LC3_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 3. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[24] LC3_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 3. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[23] LC3_COUNT_IRQ	CCP2 frame counter reached on logical channel 3. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC23_IRQENABLE[21] LC3_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 3. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC23_IRQENABLE[20] LC3_CRC_IRQ	CCP2 CRC error for logical channel 3. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected.
CCP2_LC23_IRQENABLE[19] LC3_FSP_IRQ	CCP2 false-synchronization code error for logical channel 3. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[18] LC3_FW_IRQ	CCP2 frame-width error for logical channel 3. This interrupt is generated if the frame-width constraints associated with the current data type are not respected.
CCP2_LC23_IRQENABLE[17] LC3_FSC_IRQ	CCP2 false-synchronization code error for logical channel 3. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[11] LC2_FS_IRQ	CCP2 frame-start synchronization code detection on logical channel 2. This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQENABLE[10] LC2_LE_IRQ	CCP2 line-end synchronization code detection on logical channel 2. This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQENABLE[9] LC2_LS_IRQ	CCP2 line-start synchronization code detection on logical channel 2. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[8] LC2_FE_IRQ	CCP2 frame-end synchronization code detection on logical channel 2. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream.
CCP2_LC23_IRQENABLE[7] LC2_COUNT_IRQ	CCP2 frame counter reached on logical channel 2. This interrupt is triggered when the frame counter reaches its programmable target value.
CCP2_LC23_IRQENABLE[5] LC2_FIFO_OVF_IRQ	CCP2 FIFO overflow error for logical channel 2. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC23_IRQENABLE[4] LC2_CRC_IRQ	CCP2 CRC error for logical channel 2. This interrupt is triggered when a mismatch is detected between the transmitter and receiver checksums.
CCP2_LC23_IRQENABLE[3] LC2_FSP_IRQ	CCP2 false-synchronization code error for logical channel 2. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.
CCP2_LC23_IRQENABLE[2] LC2_FW_IRQ	CCP2 frame-width error for logical channel 2. This interrupt is generated if the frame-width constraints associated with the current data type are not respected.
CCP2_LC23_IRQENABLE[1] LC2_FSC_IRQ	CCP2 false-synchronization code error for logical channel 2. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM.

**Table 8-10. ISS CCP2 Receiver Interrupts (continued)**

Event and Register	Description
CCP2_LCM_IRQENABLE[1] LCM_OCPERROR	CCP2 an interface error occurred on the master read port. This interrupt is triggered when an OCP error is detected on the master read port.
CCP2_LCM_IRQENABLE[0] LCM_EOF	Memory read channel – end of frame: This interrupt is triggered when a frame is read completely from memory.

**8.1.2.1.2.4 ISS CBUFF Interrupts**

Table 8-11 summarizes the CBUFF interrupts.

**Table 8-11. ISS CBUFF Interrupts**

Event and Register	Description
CBUFF_HL_IRQENABLE_SET[31] IRQ_CTX7_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[30] IRQ_CTX6_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[29] IRQ_CTX5_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[28] IRQ_CTX4_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[27] IRQ_CTX3_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[26] IRQ_CTX2_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[25] IRQ_CTX1_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[24] IRQ_CTX0_OVR	CBUFF overflow
CBUFF_HL_IRQENABLE_SET[23] IRQ_CTX7_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[22] IRQ_CTX6_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[21] IRQ_CTX5_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[20] IRQ_CTX4_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[19] IRQ_CTX3_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[18] IRQ_CTX2_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[17] IRQ_CTX1_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[16] IRQ_CTX0_INVALID	CBUFF invalid access
CBUFF_HL_IRQENABLE_SET[15] IRQ_CTX7_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[14] IRQ_CTX6_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[13] IRQ_CTX5_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[12] IRQ_CTX4_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[11] IRQ_CTX3_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[10] IRQ_CTX2_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[9] IRQ_CTX1_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[8] IRQ_CTX0_READY	CBUFF WB physical window ready for access by the CPU
CBUFF_HL_IRQENABLE_SET[0] IRQ_OCP_ERR	CBUFF master interface port error

**8.1.2.1.2.5 ISS BTE Interrupts**

Table 8-12 summarizes the BTE interrupts.

**Table 8-12. ISS BTE Interrupts**

Event and Register	Description
BTE_HL_IRQENABLE_SET[31] IRQ_CTX7_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 7 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, iSS BTE Buffer Prefetch</a> .

**Table 8-12. ISS BTE Interrupts (continued)**

<b>Event and Register</b>	<b>Description</b>
BTE_HL_IRQENABLE_SET[30] IRQ_CTX6_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 6 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[29] IRQ_CTX5_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 5 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[28] IRQ_CTX4_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 4 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[27] IRQ_CTX3_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 3 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[26] IRQ_CTX2_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 2 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[25] IRQ_CTX1_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 1 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[24] IRQ_CTX0_ERR	Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 0 is received, but not enough frame lines have been prefetched in the buffer. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[23] IRQ_CTX7_INVALID	Writes enable invalid access to Context 7. Reads notify when access to an unexpected location in Context 7 is requested, or the start context location access is valid, but the burst length exceeds the Context 7 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[22] IRQ_CTX6_INVALID	Writes enable invalid access to Context 6. Reads notify when access to an unexpected location in Context 6 is requested, or the start context location access is valid, but the burst length exceeds the Context 6 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[21] IRQ_CTX5_INVALID	Writes enable invalid access to Context 5. Reads notify when access to an unexpected location in Context 5 is requested, or the start context location access is valid, but the burst length exceeds the Context 5 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[20] IRQ_CTX4_INVALID	Writes enable invalid access to Context 4. Reads notify when access to an unexpected location in Context 4 is requested, or the start context location access is valid, but the burst length exceeds the Context 4 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[19] IRQ_CTX3_INVALID	Writes enable invalid access to Context 3. Reads notify when access to an unexpected location in Context 3 is requested, or the start context location access is valid, but the burst length exceeds the Context 3 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .

**Table 8-12. ISS BTE Interrupts (continued)**

Event and Register	Description
BTE_HL_IRQENABLE_SET[18] IRQ_CTX2_INVALID	Writes enable invalid access to Context 2. Reads notify when access to an unexpected location in Context 2 is requested, or the start context location access is valid, but the burst length exceeds the Context 2 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[17] IRQ_CTX1_INVALID	Writes enable invalid access to Context 1. Reads notify when access to an unexpected location in Context 1 is requested, or the start context location access is valid, but the burst length exceeds the Context 1 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[16] IRQ_CTX0_INVALID	Writes enable invalid access to Context 0. Reads notify when access to an unexpected location in Context 0 is requested, or the start context location access is valid, but the burst length exceeds the Context 0 end. See <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[15] IRQ_CTX7_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 7 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[14] IRQ_CTX6_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 6 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[13] IRQ_CTX5_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 5 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[12] IRQ_CTX4_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 4 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[11] IRQ_CTX3_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 3 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[10] IRQ_CTX2_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 2 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[9] IRQ_CTX1_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 1 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .

**Table 8-12. ISS BTE Interrupts (continued)**

Event and Register	Description
BTE_HL_IRQENABLE_SET[8] IRQ_CTX0_DONE	Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 0 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .
BTE_HL_IRQENABLE_SET[1] IRQ_INVALID	Writes enable Invalid virtual space access notification. Reads notify when access falls into a translated from the BTE region, but it is 2D access or it does not map to an active context. See <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Virtual Address Space and Context Mapping</a> .
BTE_HL_IRQENABLE_SET[1] IRQ_OCP_ERR	Writes enable notification for error on the master output interface. Reads notify when an error has occurred on the master output interface.

### 8.1.2.1.2.6 ISS SIMCOP Interrupts

[Table 8-13](#) summarizes the SIMCOP high-level interrupts mapped to the outer boundaries of the SIMCOP. For more information about interrupts generated from inside the SIMCOP modules, see the SIMCOP section.

**Table 8-13. ISS SIMCOP High-Level Interrupts**

Event and Register	Description
SIMCOP_HL_IRQENABLE_SET_i[19] CPU_PROC_START_IRQ	Interrupt used when CPU data processing is used in a macroblock processing pipeline. When the CPU receives this IRQ, data is ready to be processed. When the CPU finishes processing the data, it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit.
SIMCOP_HL_IRQENABLE_SET_i[18] SIMCOP_DMA_IRQ1	Interrupt triggered by SIMCOP DMA
SIMCOP_HL_IRQENABLE_SET_i[16] OCP_ERR_IRQ	SIMCOP master port interface error
SIMCOP_HL_IRQENABLE_SET_i[15] VLCDJ_DECODE_ERR_IRQ	A decode error has been signaled by the VLCDJ module.
SIMCOP_HL_IRQENABLE_SET_i[14] DONE_IRQ	Event triggered when hardware sequencer finishes the sequence: <ul style="list-style-type: none"> <li>The sequence step counter has reached the limit.</li> <li>All accelerator and DMA events for the last sequence step have been received.</li> </ul>
SIMCOP_HL_IRQENABLE_SET_i[13] STEP3_IRQ	Event triggered when a SIMCOP Context 3 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[12] STEP2_IRQ	Event triggered when a SIMCOP Context 2 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[11] STEP1_IRQ	Event triggered when a SIMCOP Context 1 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[10] STEP0_IRQ	Event triggered when a SIMCOP Context 0 is activated by the hardware sequencer.
SIMCOP_HL_IRQENABLE_SET_i[9] LDC_BLOCK_IRQ	A macroblock has been processed.
SIMCOP_HL_IRQENABLE_SET_i[7] ROT_A	Rotational engine interrupt
SIMCOP_HL_IRQENABLE_SET_i[6] IMX_B_IRQ	Event triggered when iMX has executed a SLEEP instruction
SIMCOP_HL_IRQENABLE_SET_i[5] IMX_A_IRQ	Event triggered when iMX has executed a SLEEP instruction
SIMCOP_HL_IRQENABLE_SET_i[4] NSF_IRQ	Event triggered by the NSD2 imaging accelerator when processing of a block is done
SIMCOP_HL_IRQENABLE_SET_i[3] VLCDJ_BLOC_IRQ	A macroblock has been processed (that is, encode and decode).
SIMCOP_HL_IRQENABLE_SET_i[2] DCT_IRQ	DCT operating is complete (configured number of MCUs for YUV4:2:0/4:2:2 mode, or number of blocks for sequential block mode).
SIMCOP_HL_IRQENABLE_SET_i[1] LDC_FRAME_IRQ	A full frame has been processed.

**Table 8-13. ISS SIMCOP High-Level Interrupts (continued)**

Event and Register	Description
SIMCOP_HL_IRQENABLE_SET_i[0] SIMCOP_DMA_IRQ0	Interrupt triggered by SIMCOP DMA

### 8.1.2.2 ISS Clocks

The clocks of ISS submodules can be cut individually using the [ISS\\_CLKCTRL](#) register. Software can poll the module status reading the appropriate bit in the [ISS\\_CLKSTAT](#) register.

When software wants to enable a submodule:

- Software sets the appropriate bit in the [ISS\\_CLKCTRL](#) register.
- Hardware enables the submodule functional and interface clocks (expected to take a few cycles).
- Hardware sets the appropriate bit in the [ISS\\_CLKSTAT](#) register.

Software must enable the modules in the correct order. The hardware imposes no particular constraint. For example, when data must be provided by the CSI2-A/CSI2-B receiver and processed by the ISP, both modules must be enabled and correctly configured before data arrives. An example of configuration order is: enabling the CSI2-A receiver powers up the complex I/O connected to the external sensor. Additionally, the ISP must be configured and the source interface must be selected. For details and the order of configuration, see the programming module of the particular submodule.

When software wants to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
  - The submodule must not generate new events.
  - The submodule must not have any pending events.
  - For initiators: The submodule must stop the generation of an interface bridge transaction.
- Software clears the appropriate bit in the [ISS\\_CLKCTRL](#) register.
- For modules having only a master port: Hardware waits until the submodule to be disconnected asserts the MStandBy signal on its master port. It asserts MWait of the submodule.

---

**NOTE:** The ISS does not assert the MWait signal when a shutdown of the module is not requested by software.

---

- Hardware cuts the submodule clocks.
- Hardware clears the appropriate bit in the [ISS\\_CLKSTAT](#) register.

[Table 8-14](#) describes the clock gating of the ISS submodule.

**Table 8-14. ISS Submodule Clock Gating**

ISS Resource	Feature On/Off Control
ISS top-level resources	Not applicable. ISS top-level resources cannot be cut. However, top-level resources support the autogating feature.
SIMCOP	<a href="#">ISS_CLKCTRL[0]</a> SIMCOP
ISP	<a href="#">ISS_CLKCTRL[1]</a> ISP
CSI2-A	<a href="#">ISS_CLKCTRL[2]</a> CSI2_A
CSI2-B	<a href="#">ISS_CLKCTRL[3]</a> CSI2_B
CCP2	<a href="#">ISS_CLKCTRL[4]</a> CCP2
ISS interconnect BTE CBUFF TCTRL	These modules cannot be switched off individually. They are required for any processing performed by SIMCOP because they are on the main data path. However, they support autogating to reduce power consumption when activity is low.

When the clock of a submodule is cut and an interface bridge request for this module is received from the ISS configuration interconnect, the ISS clock manager temporarily enables the module clock to handle the access properly.

All ISS submodules are off after reset; software must enable them before they can be used.

### 8.1.2.3 ISS Reset

The ISS can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the [ISS\\_HL\\_SYSCONFIG\[0\]](#) SOFTRESET bit to 1.
2. Read the [ISS\\_HL\\_SYSCONFIG\[0\]](#) SOFTRESET bit to check whether it equals 0, which means the reset occurred.

If after five reads, [ISS\\_HL\\_SYSCONFIG\[0\]](#) SOFTRESET still returns 1, it can be assumed that an error occurred during the reset stage.

A software reset must not reset the power manager protocols (must not reset the IDLE and STANDBY generic IPs).

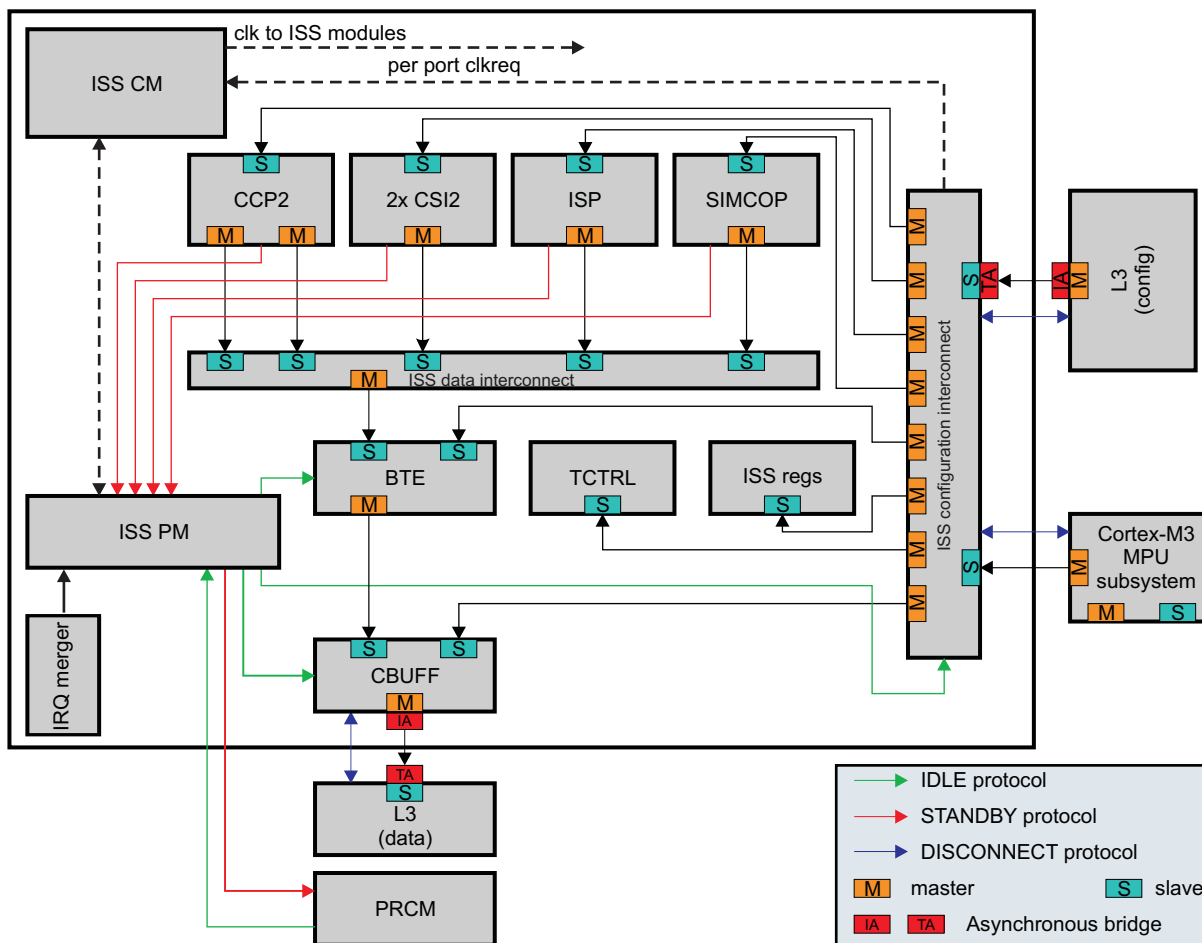

### 8.1.2.4 ISS Power Management

#### 8.1.2.4.1 ISS Power-Management Infrastructure Overview

Figure 8-4 is an overview of the ISS power management.

Figure 8-4. ISS Power Management

camss-361

**NOTE:** For power savings, the PRCM module can request idle mode from the ISS. When the ISS is not functional, software must decide when the PRCM module can send the request. For more information, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

#### 8.1.2.4.2 ISS STANDBY Mechanism

The power manager receives STANDBY information from the CCP2, CSI2-A, CSI2-B, ISP, and SIMCOP modules. These modules assert a standby signal when they have no more transactions to perform. The ISS power manager acknowledges by asserting a wait signal.

When those five modules are in standby mode, the ISS power manager initiates a STANDBY sequence for the ISS:

1. The ISS waits while the CCP2, CSI2-A, CSI2-B, ISP, and SIMCOP MStandby is asserted.
2. The ISS power manager acknowledges by asserting the CCP2, CSI2-A, CSI2-B, ISP, and SIMCOP MWait signal.
3. The ISS initiators assert only the MStandBy signal when they receive responses to all sent requests.

Therefore, when all initiators have asserted MStandBy, the ISS interconnect has no more pending traffic (although configurable, only nonposted writes must be used for error reporting).

4. The ISS power manager sends an IDLE request to the BTE. This IDLE request is used to drain BTE data. It does not affect the configuration port.
5. The BTE drains all transactions.
6. The BTE acknowledges the IDLE request.
7. The ISS power manager sends an IDLE request to the CBUFF. This IDLE request is used to drain CBUFF data. It does not affect the configuration port.
8. CBUFF drains all transactions.
9. CBUFF disconnects the interface master port connected to the L3 interconnect.
10. CBUFF acknowledges the IDLE request.
11. The ISS power manager asserts the MStandBy signals connected to the system PRCM module.
12. The PRCM module acknowledges by asserting the MWait signal.

A functional standby transition can be aborted when one of the CCP2, CSI2-A, CSI2-B, ISP, or SIMCOP modules deasserts the MStandBy signal. The corresponding MWait signal is deasserted only when the ISS interconnect, BTE, CBUFF, and ISS interface master port are ready to receive requests.

When one of the CCP2, CSI2-A, CSI2-B, ISP, or SIMCOP modules must perform accesses to the ISS interface master port, it deasserts the MStandBy signal. The ISS power manager executes the following sequence to leave the STANDBY state:

1. The ISS power manager deasserts the MStandby signal.
2. The ISS waits until the PRCM module deasserts the MWait signal.
3. The ISS power manager requests CBUFF to go into functional mode.
4. CBUFF connects the interface port.
5. The ISS power manager requests the BTE to go into functional mode.
6. The ISS power manager waits until CBUFF and BTE acknowledge functional mode.
7. The ISS deasserts the MWait signal of the module requesting access.

Abort of the standby-to-functional mode transition is not supported. The ISS power manager completes the standby-to-functional transition and then allows a new functional-to-standby transition.

Typically, the MStandby signal is used for two purposes. Software chooses one of the following behaviors through PRCM configuration:

- During blanking periods: The ISS asserts the MStandBy signal between frames when it has no more data to send. The PRCM module can use this information to switch off the L3 interconnect and save some dynamic power. However, the PRCM module is not allowed to cut the ISS functional clock in that case, because it is needed to receive the next frame.
- For ISS shutdown: The ISS asserts MStandBy when it has no more transactions to perform. The PRCM module then initiates an IDLE sequence. Once the ISS acknowledges the transition into idle mode, the PRCM module can cut the ISS clock and power.

The internal standby mode can be reached only when CCP2, CSI2-A, CSI2-B, SIMCOP, ISP, ISS data interconnect, BTE, and CBUFF are in IDLE or STANDBY state. Choosing no-idle or no-standby mode for any of these modules prevents the ISS from going into STANDBY state.

Four modes for standby control are supported, configured through the [ISS\\_HL\\_SYSCONFIG\[5:4\]](#) STANDBYMODE bit field:

- Smart-standby-wakeup mode: This is the mode normally used. When in this mode, the ISS asserts the MStandBy signal when the MStandBy of all ISS internal initiators is asserted and the ISS data interconnect, BTE, and CBUFF are in IDLE state.
- Smart-standby mode: The ISS has no wake-up event. This mode is equivalent to smart-standby-wakeup mode.
- Force-standby mode: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS asserts MStandBy unconditionally. Software must ensure that the ISS is in a correct quiet state before programming this mode.

- No-standby mode: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS never asserts the MStandBy signal.

#### 8.1.2.4.3 ISS IDLE Mechanism

The PRCM module can request the ISS to go into IDLE state when the ISS has asserted its MStandBy output.

In a normal case, software must ensure that the ISS is in a quiet state before allowing the PRCM module to send an IDLE request to the ISS:

- The ISS has no more traffic to generate.
- The ISS cannot generate any new interrupts.
- The ISS has no pending interrupts.

When an IDLE request is received from the PRCM module, the ISS power manager verifies that the ISS MWait input has been asserted and that all ISS interrupt outputs are deasserted. It then starts the STANDBY-to-IDLE transition:

1. Send IDLE request to the ISS configuration interconnect.
2. The ISS configuration interconnect requests disconnection of both ISS interface slave ports. Disconnection is done by the master:
  - It stops accepting new requests and drains currently ongoing ones.
  - It waits for completion of all ongoing transactions.
3. The ISS configuration interconnect acknowledges the IDLE transition.
4. The ISS power manager acknowledges the IDLE request from the PRCM module.
5. The PRCM module can cut the ISS clock and power.

The PRCM module first enables the ISS power and clock before requesting the ISS to go into functional state by deasserting the SIdleReq signal. The ISS power manager then executes the wake-up sequence:

1. Request the ISS interconnect to go into functional state.
2. The ISS interconnect connects the ISS slave ports.
3. The ISS interconnect acknowledges transition into functional mode.
4. The ISS power manager acknowledges transition into functional mode (ISS output SIdleAck = 00).

Four modes for IDLE control are supported, controlled through the [ISS\\_HL\\_SYSCONFIG\[3:2\]](#) IDLEMODE bit field:

- Smart-idle-wakeup mode [b11]: This is the mode normally used. When in this mode, the ISS acknowledges a request to go idle from the power manager after having performed all hardware operations necessary for the IAF to be in a correct quiet state.
- Smart-idle mode [b10]: This is equivalent to smart-idle-wakeup mode.
- Force-idle mode [b00]: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, the ISS acknowledges a request to go idle from the power manager with no hardware condition. Software must ensure that the ISS is in a correct quiet state before requesting a force-idle transition.
- No-idle mode [b01]: When in this mode, the ISS disregards any request to go idle from the power manager.

### 8.1.3 ISS Register Manual

#### 8.1.3.1 ISS Instance Summary

Table 8-15 is the ISS instance.

**Table 8-15. ISS Instance Summary**

Module Name	Module Base Address	Size
ISS_TOP	0x5200 0000	256 bytes

**NOTE:** This section contains the ISS TOP registers only. For submodule register details, see the register manual of the particular submodule.

#### 8.1.3.2 ISS Registers

##### 8.1.3.2.1 ISS TOP Register Summary

Table 8-16 summarizes the ISS TOP register mapping.

**Table 8-16. ISS TOP Register Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	ISS_TOP Base Address

## 8.2 ISS Interfaces

### 8.2.1 ISS Interfaces Overview

Along with the submodules, the ISS has two serial camera interfaces (primary and secondary) and a parallel interface. The primary serial interface (CSI2-A) supports MIPI® CSI2 protocol with four data lanes, and the secondary serial interface (CSI2-B/CCP2) supports CSI2 protocol with two data lanes or CCP2 protocol. The parallel interface (CPI) supports up to 16 data lanes. All interfaces can use the image signal processor (ISP), but not concurrently. When one interface uses the ISP, the other must send data to memory. However, the ISP can still be used to process this data in memory-to-memory. Time multiplex processing is also possible.

[Figure 8-5](#) shows the ISS interfaces and interconnects.

Figure 8-5. ISS Interfaces and Interconnects Highlight

camss-006

**NOTE:** In the device, the number 2 in the cam2 interface name does not mean there are two camera parallel interfaces available in the device. The cam2 interface name defines the camera parallel interface available in the device versus the legacy device.

### 8.2.1.1 ISS Interface Features

The camera subsystem supports the following features:

- System interfaces and interconnects:
  - Two 32-bit-wide configuration interfaces:
    - Interface to Cortex™-M3 microprocessor unit (MPU): Synchronous to the functional clock
    - Interface to Cortex™-A9 MPU and system direct memory access (sDMA): Asynchronous from the functional clock
  - 128-bit-wide data interface to level 3 (L3) interconnect: Asynchronous from the functional clock
    - Shared interface level 2 (L2) in IVA-HD module for hardware encoding
    - Outside connection using the L3 interconnect through the TILER to the synchronous dynamic random access memory (SDRAM) controller (SDRC), which acts as the primary interface between the SDRAM and the ISS functional block
  - The ISS has a local interconnect that connects all modules inside the ISS.
  - BTE:
    - Tightly coupled with the TILER to support efficient rotation
  - CBUFF:
    - Maps a linear space into a circular buffer
    - The buffer is physically located in system memory.
  - TCTRL:
    - Control signal generation for flash prestrobe and strobe
    - Camera global reset control
- Camera interfaces:
  - Two CSI2 camera interfaces: CSI2-A (primary) and CSI2-B (secondary)
    - Transfer pixels and data received by the CSI2 digital physical layer receiver to the system memory or to the ISP
    - Use unidirectional data link
    - CSI2-A supports four configurable data links in addition to the clock signaling.
    - CSI2-B supports two configurable data links in addition to the clock signaling.
    - Maximum data rate of 1 Gbps per data lane
    - Data merger for 2-, 3-, or 4-data lane configuration
    - Maximum data rate of 1 Gbps per data lane, possible configurations are:
      - One data lane: 1000 Mbps (824 Mbps if lane 4 is used)
      - Two data lanes: 2 × 1000 Mbps (2 × 824 Mbps if lane 4 is used)
      - Three data lanes: 3 × 1000 Mbps (3 × 824 Mbps if lane 4 is used)
      - Four data lanes: 4 × 824 Mbps
    - Error detection and correction by the protocol engine
    - Direct memory access (DMA) engine integrated with dedicated first in first out (FIFO)
    - One-dimensional (1D) and two-dimensional (2D) addressing mode
    - Burst support
    - Streaming burst support (64- or 32-bit)
    - Eight contexts to support eight dedicated configurations of virtual channel ID and data types
    - Ping-pong mechanism for double-buffering
    - All primary and secondary MIPI-defined formats are supported.
    - Conversion of the RGB formats
    - On-the-fly differential pulse code modulation (DPCM) decompression
    - On-the-fly image cropping and A-law/DPCM compression

- Configuration of the complex input/output (I/O) physical layer (PHY) (MIPI D-PHY-compliant receiver PHY solution [D-PHY mode]/CCP2-compatible receiver PHY solution (CCP2 mode))
- CCP2 camera interface (secondary)
  - Four logical channels
  - Transfer pixels and data received by the complex I/O PHY (CCP2 D-PHY RX to the system memory or the ISP)
  - Use unidirectional data link
  - Maximum data rate of 650 Mbps
  - DMA engine integrated with dedicated FIFO
  - 1D and 2D addressing mode
  - False synchronization code protection
  - Ping-pong mechanism for double-buffering
  - RGB, RAW, YUV, and JPEG formats supported
  - On-the-fly DPCM decompression
  - On-the-fly image cropping and A-Law/DPCM compression
- Parallel interface (CPI)
  - 16 bits wide
  - up to 148.5 MPix/s
  - BT656 and SYNC mode (HS, VS, FIELD, WEN)
- System memory data read back port (supported by the CCP2 protocol engine)
  - RAW 6, 7, 8, 10, 12, 14, 16 formats supported
  - DPCM and A-law decompression
  - Supports image cropping for compressed or uncompressed data

---

**NOTE:** Rotated DPCM data is not supported.

---

## 8.2.2 ISS Interfaces Environment

### 8.2.2.1 ISS Interfaces Signal Descriptions

Table 8-37 summarizes the I/O signals.

**Table 8-37. ISS I/O Description**

Signal Name	I/O <sup>(1)</sup>	Description	Serial Mode CCP2	Serial Mode CSI2	Parallel Mode CPI

cam2_hs	I/O	Parallel mode horizontal frame synchronization			x
cam2_d[15:0]	I	Parallel mode data lanes (16 signals)			x

---

**NOTE:** Lane polarity can be changed in complex I/O. For more information, see [Section 8.2.2.2, ISS Interface Modes](#).

---

**NOTE:** At least one data lane must be configured for using the CSI2-A and CSI2-B interfaces. The signals are also configurable from the control module. Thus, they are not required to be at a certain location to act as clock or data; this can be configured.

---

**NOTE:** The Parallel interface (CPI), CCP2, and CSI2-B share pins. Their modes are not supported as a pin configuration mux option. The modes are configured from the CSI2-B/CCP2 CAMERARX configured from the system control module (see [Chapter 18, Control Module](#)).

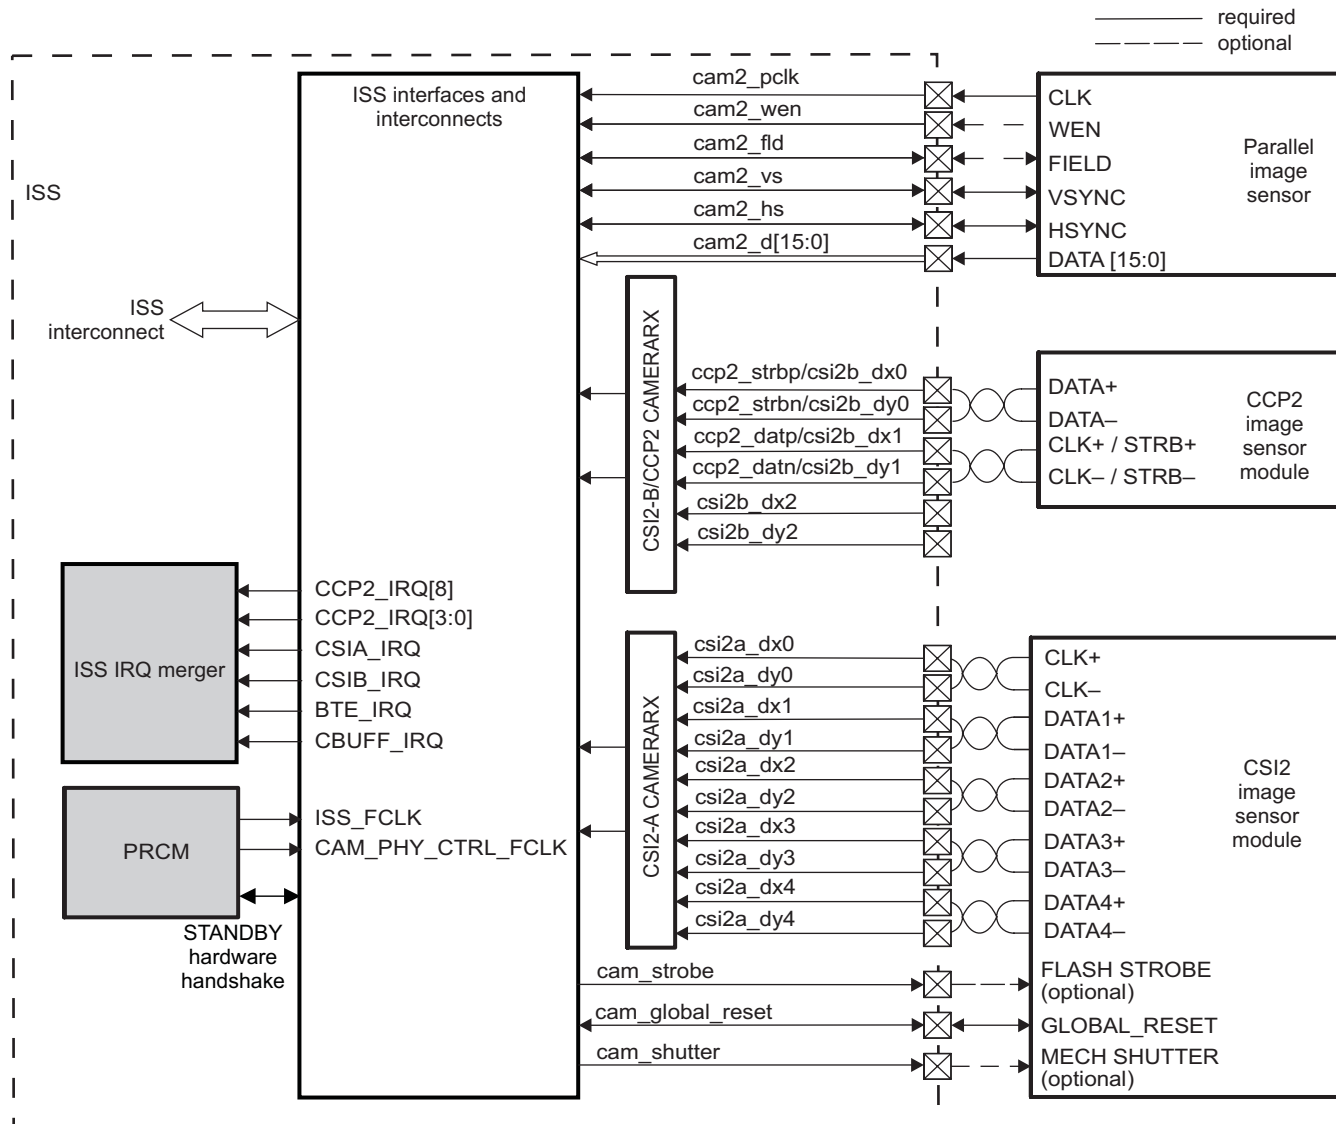

---

### 8.2.2.2 ISS Interfaces Modes

The camera subsystem can manage a parallel interface and two serial image sensors. Depending on the configuration of the shared pins, two of the interfaces can be active at the same time. However, only one data flow can use the ISP. Moreover, if the parallel interface is used data from it goes to ISP and the other used interface must send it to memory. [Figure 8-6](#) shows an example block diagram of the interface configuration. Each serial port clock lane is configurable. The MIPI CSI2 protocol requires only a clock lane setup. The data lane configuration is optional. For more information, see [Section 8.2.5.1.1, ISS CSI2 Protocol and Data Format](#).

Figure 8-6. ISS CSI2-A, CSI2-B/CCP2 Serial Interface Configuration

camss-005u

**NOTE:** Depending on the needs, `cam_strobe`, `cam_global_reset`, and `cam_shutter` can be connected to the image sensor module rather than the CSI2 image sensor module.

**NOTE:** Dedicated power, reset, and clock management (PRCM) module pins for power and ground are provided for external sensors: `vdda_csi2a`, `vdda_csi2b`, `vssa_csi2a`, and `vssa_csi2b`.

A graphical representation of the pins for connecting external sensors to the ISS shows a variety of connectivity configurations that are possible by setting the PHY immediately before the receivers, and a variety of output paths, including some sensor data through the receivers to memory or the ISP. [Table 8-38](#) lists some of the connectivity possibilities; the ISP can take only one input lane at a time. For more information about the operating properties and configuration of the CAMERARX PHY, see [Section 8.2.3, ISS CSI2 PHY](#).

**Table 8-38. ISS Interfaces Connectivity Scheme Example Scenarios**

CSI2-A	On, 4DL CSI2-A <sup>(1)</sup> to ISP	On, 2DL CSI2-A <sup>(2)</sup> to Memory	Off	On, 2DL CSI2-A <sup>(2)</sup> to memory	On, 3DL CSI2-A <sup>(2)</sup> to ISP/memory	Off	Off

csi2b_dy0/ccp2_strbn	x		x	x	x	x	x
csi2b_dx1/ccp2_datp	x		x	x	x	x	x
csi2b_dy1/ccp2_datn	x		x	x	x	x	x
csi2b_dx2	x				x		x
csi2b_dy2	x				x		x
cam2_pclk		x	x				
cam2_wen		x	x				
cam2_fld		x	x				
cam2_vs		x	x				
cam2_hs		x	x				
cam2_d[15:0]		x	x				

<sup>(1)</sup> Full: All data/clock lanes are connected.

<sup>(2)</sup> Limited: Some data/clock lanes are connected.

---

**NOTE:** The ISP can take only one input at a time. The other inputs must go to memory and then be processed after the ISP processes the input that was received first.

---

In looking at the sample connections between the ISS through the receivers and external sensors, it is apparent that the lanes of the input can be adjusted for certain needs. For example, it is not necessary that the CSI2-A has four data lanes connected at the same time. The restriction is that CSI2-B is limited to two data lanes. Because CSI2-B and CCP2 share pins, they cannot be used simultaneously. CSI2-A and CSI2-B/CCP2 can function at the same time by sending data to memory. In this manner, external sensors can be connected any way possible for best performance and results.

### 8.2.2.3 ISS Interfaces CPI Data Formats

#### 8.2.2.3.1 ISS Interfaces CPI Generic Configuration Protocol and Data Format (8, 10, 12, 16 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8- to 16-bit-wide data signals.

In this configuration, no assumptions are made about the data format of pixels, but the dynamic range is limited to 8, 10, 12, and 16 bits (data can be pure Luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on cam2\_d, where 1 pixel is sampled for every cam2\_pclk rising edge (or falling edge, depending on the configuration of cam2\_pclk polarity).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (cam2\_hs) and vertical synchronization (cam2\_vs). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

---

**NOTE:** For correct operation, the clock cam2\_pclk must run during blanking periods (cam2\_hs and cam2\_vs inactive). cam2\_pclk must start before sending cam2\_d and start cam2\_vs and cam2\_hs.

---

Figure 8-7 and Figure 8-8 show the frame and data timing, based on synchronization signals in the parallel No BT configuration.

**Figure 8-7. ISS Interfaces CPI Synchronization Signals and Frame Timing in SYNC Mode**

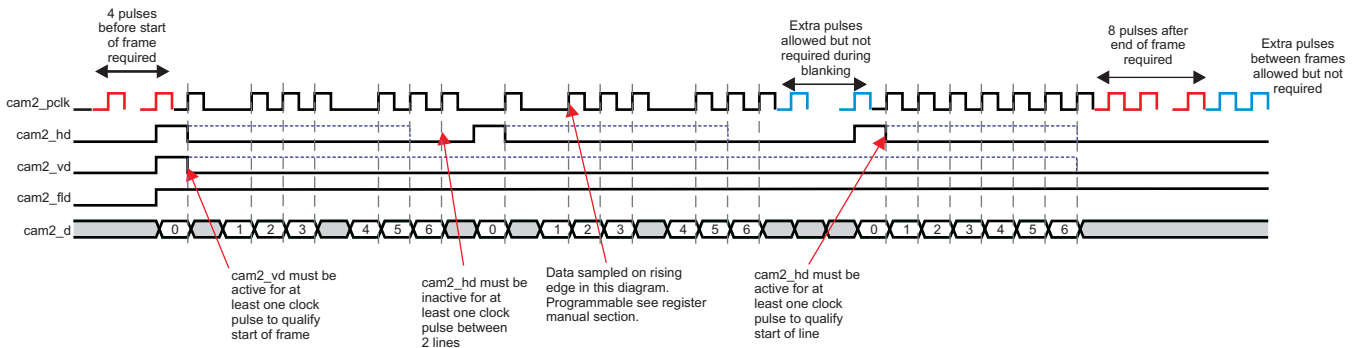

**Figure 8-8. ISS Interfaces CPI Synchronization Signals and Data Timing in SYNC Mode**

**NOTE:** The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least four clock pulses are required before sending active image data and synchronization information; eight clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

Figure 8-9 shows the timing diagram of the SYNC move clock gating.

**Figure 8-9. ISS Interfaces CPI SYNC Mode Clock Gating**

camss-009

### 8.2.2.3.2 ISS Interfaces CPI ITU-R BT.656/1120 422 Protocol and Data Formats (8, 10 Bits)

The ISS CPI supports data in ITU-R BT.656 format. The ITU-R BT.656 standard specifies a method of transferring YUV4:2:2 data over an 8- or 10-bit video interface.

Figure 8-10 shows the data timing diagram with embedded synchronization signals.

**Figure 8-10. ISS Interfaces CPI Data Timing With Embedded Synchronization Signals (8-Bit Case)**

camss-010

In BT.656, the data words (8- or 10-bit) in which the 8 most-significant bits (MSBs) are all set to 1, or all set to 0, are reserved.

**NOTE:** The ITU-R BT.656 specification is for 525-line and 625-line, digital component video signals in compliance with ITU-R BT.601. See the CCIR document Rec. 656-1 for detailed information about the interface.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved Luminance and Chroma samples and the following byte Y2n + 1 corresponds to the next Luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cam2\_hs and cam2\_vs are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video data block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: FF 00 00 XY. The first 3 bytes are a fixed preamble (see the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 8-39 lists the video timing reference codes for SAV and EAV.

**Table 8-39. ISS Interfaces CPI Video Timing Reference Codes for SAV and EAV**

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 8-40 describes the F, V, and H signals.

**Table 8-40. ISS Interfaces CPI F, V, H Signal Descriptions**

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the ISIF\_REC656IF[0] ECCFVH bit.

---

**NOTE:** The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

---

Table 8-41 lists the F, V, and H protection (error-correction) bits.

**Table 8-41. ISS Interfaces CPI F, V, H Protection (Error-Correction) Bits**

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

When operating in ITU-R BT.656 mode, data is stored in SDRAM according to the format listed in Table 8-42 when the ISIF\_REC656IF[1] R656ON bit is enabled.

**Table 8-42. ISS Interfaces CPI ITU-R BT.656 Mode Data Format in SDRAM**

## 8.2.3 ISS CSI2 PHY

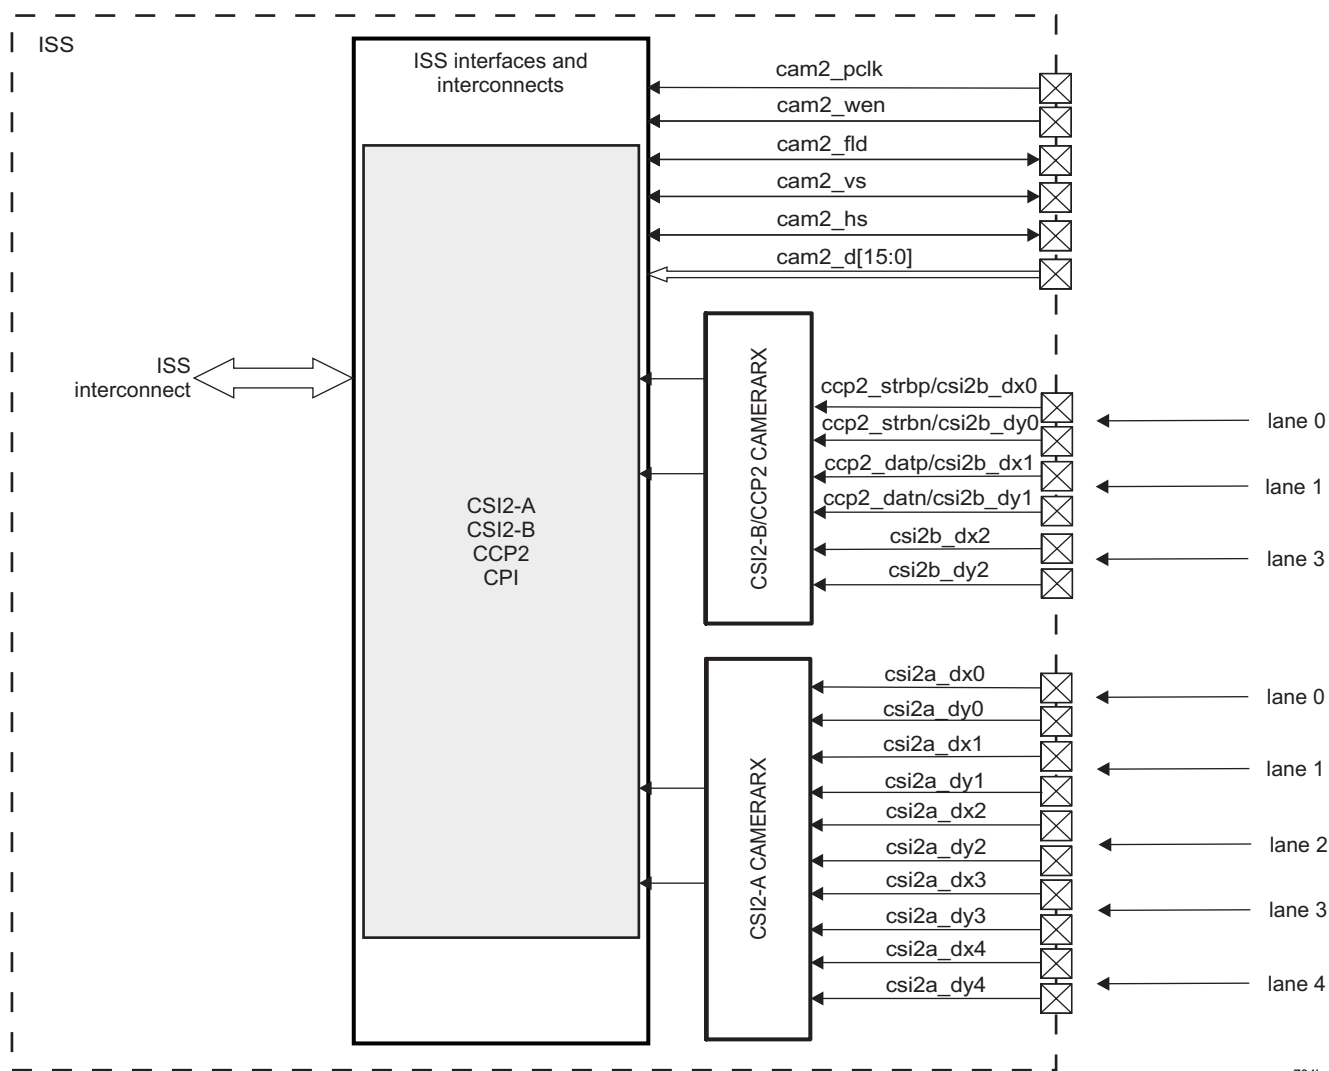

### 8.2.3.1 ISS CSI2 PHY Overview

Two MIPI D-PHY-compliant CAMERARX PHY receivers immediately before the ISS interfaces act as a physical connection and configuration of clock/data lanes with external sensors. CAMERARX PHY supports up to four configurations, depending on the required number of D-PHY data lane external sensors. The receivers are compatible with the *MIPI D-PHY Specification v0.92*. The selection of CAMERARX in D-PHY mode, parallel mode, or CCP2 mode must be done before reset and not on the fly.

The PHY is controlled and must be configured first from the control module for pad configuration. The differential data/clock lanes coming into the CSI2-A and CSI2-B CAMERARX are configured from registers explained in [Section 18.4.8.4](#) (see register CONTROL\_CAMERA\_RX).

As mentioned previously, two PHYs are integrated in the device. The CSI2-A CAMERARX contains four data lanes, as shown in [Figure 8-11](#); CSI2-B is the same except that it has two data lanes plus a clock/strobe lane. The figure also shows case CSI2-A, with four data lanes and one clock, listed in [Table 8-38](#).

**Figure 8-11. ISS Interfaces CSI2-A PHY Diagram Four D-PHY Data Lane Configuration**

**NOTE:** If CCP2 mode is chosen for use in the CSI2-B/CCP2 CAMERARX, then LANE 0 and LANE 1 are used only as datp/datn and strbp/strbn.

**NOTE:** LANE 4 can be used only as a data lane, never as a clock lane. All other configurations are possible. Also, a speed restriction is present when lane 4 is used; then all data lanes perform at up to 824 Mbps instead of 1000 Mbps.

**NOTE:** Depending on the selected mux mode from the Control Module, the Parallel interface (CPI) signals can also be going through one of the CAMERARXs

CSI2-A and CSI2-B/CCP2 CAMERARX represent the overall PHY solution for connecting external sensors to feed the ISS. The MIPI D-PHY function can support up to four data lane modules and one clock lane module. Reverse direction escape mode is not supported. The lane module polarity and positions are configurable; that is, any lane module can be chosen as the clock lane module, and the DX/DY data pad for each lane module can be configured as DP or DN pins defined. The configuration and the selection of D-PHY mode, data/clock, or data/strobes are done through the control module (see [Chapter 18, Control Module](#)). The only exception is the four-data-lane use case, in which one corner lane is allowed to be only a data lane. For the CCP2 function, the CAMERARX PHY solution supports one data/strobe or data/clock lane module. The data lane module and strobe lane module must be physically adjacent. CAMERARX supports serial configuration protocol for the configuration interface.

### 8.2.3.2 ISS CSI2 PHY Functional Description

#### 8.2.3.2.1 ISS CSI2 PHY Functional Configuration

The CSI2 PHY converts the bitstream, divided into 1 to 4 serial data lanes, into a bitstream compatible with the CSI2 receiver and one clock lane.

The [CSI2\\_COMPLEXIO\\_IRQSTATUS](#) register logs complex I/O events of the following types:

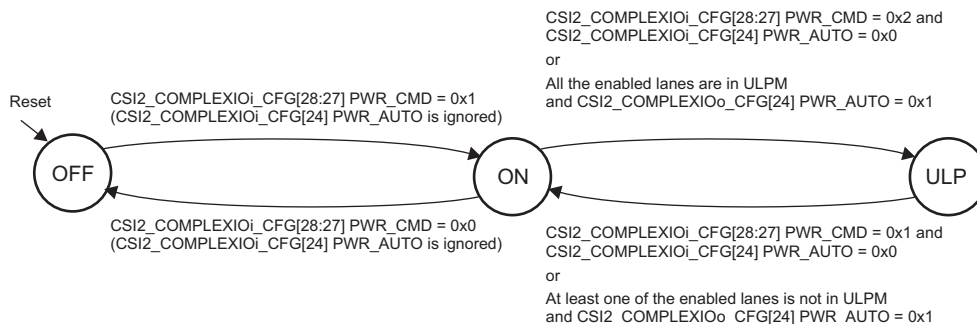

- Line power-state change (all lanes in ultralow-power mode [ULPM], at least one lane exits ULPM, etc.)
- Error on one lane

The CSI2 receiver embeds two registers to configure/read some complex I/O parameters:

- The [REGISTER0](#) register detects clock miss with respect to the *MIPI D-PHY Specification v0.92* and control timing.
- The [REGISTER1](#) register reports completion of reset on the different parts of the module and configures the timing parameters.
- The [CSI2\\_COMPLEXIO\\_CFG](#) registers contain the PWR\_AUTO and PWR\_CMD bit fields, which affect the power management of the two complex I/Os.

The complex I/O has three power modes: on, off, and ultralow power (ULP). These modes can reflect the ON or ULP states of the five differential lines if the [CSI2\\_COMPLEXIO\\_CFG\[24\]](#) PWR\_AUTO bit is set to 1. If the PWR\_AUTO bit is at reset value (0), the complex I/O power state is controlled by the [CSI2\\_COMPLEXIO\\_CFG\[28:27\]](#) PWR\_CMD bit field, which directly defines the power state. [Figure 8-12](#) shows the complex I/O power finite state-machine (FSM).

**Figure 8-12. ISS CSI2 Complex I/O Power FSM**

camss-253

Another register, [CSI2\\_TIMING](#), is used to control the power state of the complex I/O modules with regard to the differential line state. This register controls the mode of the two complex I/Os (RxMode and NoRxMode) and the delay between the differential lanes in STOP state and the complex I/O on NoRxMode. The [CSI2\\_TIMING\[15\] FORCE\\_RX\\_MODE\\_IO1](#) bit sets the complex I/O in RxMode or NoRxMode (stopped mode). The [FORCE\\_RX\\_MODE\\_IO](#) bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bits ([CSI2\\_TIMING\[14\] STOP\\_STATE\\_X16\\_IO1](#), [CSI2\\_TIMING\[13\] STOP\\_STATE\\_X4\\_IO1](#), and the [CSI2\\_TIMING\[12:0\] STOP\\_STATE\\_COUNTER\\_IO1](#) bit field) configure the delay between line stop mode and complex I/O stop mode. The delay represents the number of functional clock (ISS\_FCLK) cycles and can be calculated as follows:

Total delay in ISS\_FCLK cycle = [CSI2\\_TIMING.STOP\\_STATE\\_COUNTER\\_IO](#) x (1+[CSI2\\_TIMING.STOP\\_STATE\\_X16\\_IO](#) x 15) x (1+[CSI2\\_TIMING.STOP\\_STATE\\_X4\\_IO](#) x 3).

[Table 8-43](#) lists the possible values of the delay, in terms of the ISS\_FCLK cycles, depending on the values of the [STOP\\_STATE\\_X16\\_IO](#) and [STOP\\_STATE\\_X4\\_IO](#) bits.

**Table 8-43. ISS CSI2 Possible Time-Out Value for RxMode Counter**

<a href="#">STOP_STATE_X16_IO</a>	<a href="#">STOP_STATE_X4_IO</a>	Possible Delay Value (in Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The FORCERXMODE signal is used at initialization time (complex I/O). [Figure 8-13](#) describes the ForceRxMode and StopState FSM to assert and deassert the FORCERXMODE signal and to monitor STOPSTATE from the complex I/O.

**Figure 8-13. ISS CSI2 RxMode and StopState FSM**

### 8.2.3.2.2 ISS CSI2 PHY and Link Initialization Sequence

The MIPI D-PHY initialization sequence is not implemented within CAMERARX. The CSI2-A receiver is expected to coordinate the PHY initialization. The controller must ensure that the PHY is held in RESET/WAIT for RX mode until the D-PHY transmitter is powered up and the link comes to the defined state. The controller can use the STOPSTATE and FORCERXMODE signals of CAMERARX for this purpose. STOPSTATE indicates the line states, while FORCERXMODE forces the receiver state-machine into "wait for stop state." One possible initialization sequence is:

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2 receiver registers to be ready to receive signals/data from the CSIPHY:
  - (a) Configure all needed CSI2 registers:
    - (i) Set [CSI2\\_COMPLEXIO\\_CFG\[18:16\] DATA4\\_POSITION](#).
    - (ii) Set [CSI2\\_COMPLEXIO\\_CFG\[14:12\] DATA3\\_POSITION](#).
    - (iii) Set [CSI2\\_COMPLEXIO\\_CFG\[10:8\] DATA2\\_POSITION](#).
    - (iv) Set [CSI2\\_COMPLEXIO\\_CFG\[6:4\] DATA1\\_POSITION](#).
    - (v) Set [CSI2\\_COMPLEXIO\\_CFG\[2:0\] CLOCK\\_POSITION](#).

- (vi) Set the CONTROL\_CAMERA\_RX[20:19] CAMERARX\_CSI22\_CAMMODE or CONTROL\_CAMERA\_RX[17:16] CAMERARX\_CSI21\_CAMMODE.

**CAUTION**

This must be done before the CSIPHY is active.

- (vii) A dedicated internal clock gate control is present for each PHY. Enable or disable the internal CTRLCLK from the CAMERARX\_CSI22\_CTRLCLKE[21] CAMERARX\_CSI22\_CTRLCLKE bit or the [18] CAMERARX\_CSI21\_CTRLCLKE bit.

2. CSIPHY and link initialization sequence:

- (a) Deassert the CSIPHY reset.

- (i) Set CSI2\_COMPLEXIO\_CFG[30] RESET\_CTRL to 0x1.

**CAUTION**

For the CSI2\_COMPLEXIO\_CFG[29] RESET\_DONE bit to be set to 0x1 (reset completed), the external sensor must to be active and sending the MIPI HS BYTECLK.

The following registers can be set only after deasserting the CSIPHY reset and before asserting the FORCERXMODE signal:

- REGISTER0
- REGISTER1
- REGISTER2

- (b) Assert the FORCERXMODE signal:

- (i) Set CSI2\_TIMING[15] FORCE\_RX\_MODE\_IO1 to 0x1.

- (c) Connect pulldown on link (DP/DN) by asserting the respective PIPD\* signals (PIPD\* = 0):

For CSI2-A CAMERARX pulldown on signals through padconf registers:

- csi21\_dx4:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[8] CSI21\_DX4\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[4] CSI21\_DX4\_PULLTYPESELECT = 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[3] CSI21\_DX4\_PULLUDENABLE = 0x1
- csi21\_dy4:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[24] CSI21\_DY4\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[20] CSI21\_DY4\_PULLTYPESELECT = 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[19] CSI21\_DY4\_PULLUDENABLE = 0x1
- csi21\_dx3:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[8] CSI21\_DX3\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[4] CSI21\_DX3\_PULLTYPESELECT = 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[3] CSI21\_DX3\_PULLUDENABLE = 0x1

- csi21\_dy3:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[24] CSI21\_DY3\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[20] CSI21\_DY3\_PULLTYPESELECT= 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[19] CSI21\_DY3\_PULLUDENABLE = 0x1
- csi21\_dx2:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY2[8] CSI21\_DX2\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY2[4] CSI21\_DX2\_PULLTYPESELECT= 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY2[3] CSI21\_DX2\_PULLUDENABLE = 0x1
- csi21\_dy2:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY2[24] CSI21\_DY2\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY2[20] CSI21\_DY2\_PULLTYPESELECT= 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY3[19] CSI21\_DY2\_PULLUDENABLE = 0x1
- csi21\_dx1:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[8] CSI21\_DX1\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[4] CSI21\_DX1\_PULLTYPESELECT= 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[3] CSI21\_DX1\_PULLUDENABLE = 0x1
- csi21\_dy1:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[24] CSI21\_DY1\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[20] CSI21\_DY1\_PULLTYPESELECT= 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[19] CSI21\_DY1\_PULLUDENABLE = 0x1
- csi21\_dx0:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[8] CSI21\_DX0\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[4] CSI21\_DX0\_PULLTYPESELECT= 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[3] CSI21\_DX0\_PULLUDENABLE = 0x1
- csi21\_dy0:
  - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[24] CSI21\_DY0\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[20] CSI21\_DY0\_PULLTYPESELECT= 0x0
  - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[19] CSI21\_DY0\_PULLUDENABLE = 0x1

For CSI2-B/CCP2 CAMERARX pulldown on signals through padconf registers:

- csi22\_dx2:

- CONTROL\_CORE\_PAD0\_DPM\_EMU19\_PAD1\_CSI22\_DX2[24]  
CSI22\_DX1\_INPUTENABLE = 0x1
  - CONTROL\_CORE\_PAD0\_DPM\_EMU19\_PAD1\_CSI22\_DX2[20]  
CSI22\_DX1\_PULLTYPESELECT = 0x0
  - CONTROL\_CORE\_PAD0\_DPM\_EMU19\_PAD1\_CSI22\_DX2[19]  
CSI22\_DX1\_PULLUDENABLE = 0x1
  - csi22\_dy2:
    - CONTROL\_CORE\_PAD0\_CSI22\_DY2[8] CSI22\_DY1\_INPUTENABLE = 0x1
    - CONTROL\_CORE\_PAD0\_CSI22\_DY2[4] CSI22\_DY1\_PULLTYPESELECT = 0x0
    - CONTROL\_CORE\_PAD0\_CSI22\_DY2[3] CSI22\_DY1\_PULLUDENABLE = 0x1
  - csi22\_dx1:
    - CONTROL\_CORE\_PAD0\_CSI22\_DX1\_PAD1\_CSI22\_DY1[8] CSI22\_DX1\_INPUTENABLE = 0x1
    - CONTROL\_CORE\_PAD0\_CSI22\_DX1\_PAD1\_CSI22\_DY1[4]  
CSI22\_DX1\_PULLTYPESELECT = 0x0
    - CONTROL\_CORE\_PAD0\_CSI22\_DX1\_PAD1\_CSI22\_DY1[3]  
CSI22\_DX1\_PULLUDENABLE = 0x1
  - csi22\_dy1:
    - CONTROL\_CORE\_PAD0\_CSI22\_DX1\_PAD1\_CSI22\_DY1[24] CSI22\_DY1\_INPUTENABLE = 0x1
    - CONTROL\_CORE\_PAD0\_CSI22\_DX1\_PAD1\_CSI22\_DY1[20]  
CSI22\_DY1\_PULLTYPESELECT = 0x0
    - CONTROL\_CORE\_PAD0\_CSI22\_DX1\_PAD1\_CSI22\_DY1[19]  
CSI22\_DY1\_PULLUDENABLE = 0x1
  - csi22\_dx0:
    - CONTROL\_CORE\_PAD0\_CSI22\_DX0\_PAD1\_CSI22\_DY0[8] CSI22\_DX0\_INPUTENABLE = 0x1
    - CONTROL\_CORE\_PAD0\_CSI22\_DX0\_PAD1\_CSI22\_DY0[4]  
CSI22\_DX0\_PULLTYPESELECT = 0x0
    - CONTROL\_CORE\_PAD0\_CSI22\_DX0\_PAD1\_CSI22\_DY0[3]  
CSI22\_DX0\_PULLUDENABLE = 0x1
  - csi22\_dy0:
    - CONTROL\_CORE\_PAD0\_CSI22\_DX0\_PAD1\_CSI22\_DY0[24] CSI22\_DY0\_INPUTENABLE = 0x1
    - CONTROL\_CORE\_PAD0\_CSI22\_DX0\_PAD1\_CSI22\_DY0[20]  
CSI22\_DY0\_PULLTYPESELECT = 0x0
    - CONTROL\_CORE\_PAD0\_CSI22\_DX0\_PAD1\_CSI22\_DY0[19]  
CSI22\_DY0\_PULLUDENABLE = 0x1
- (d) Power up the CSIPHY:
- (i) Set [CSI2\\_COMPLEXIO\\_CFG\[28:27\]](#) PWR\_CMD to 0x1.
- (e) Check whether the state status reaches the ON state:
- [CSI2\\_COMPLEXIO\\_CFG\[26:25\]](#) PWR\_STATUS = 0x1
- (f) Wait for STOPSTATE = 1 (for all enabled lane modules):
- (i) The timer is set through the [CSI2\\_TIMING\[14:0\]](#) bit field. The reset value can be kept.
  - (ii) Wait until [CSI2\\_TIMING\[15\]](#) FORCE\_RX\_MODE\_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.
- (g) Release PIPD\* (= 1).
- For CSI2-A CAMERARX pullup on signals through padconf registers:
- csi21\_dx4:

- CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[4]  
CSI21\_DX4\_PULLTYPESELECT = 0x1
  - csi21\_dy4:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX4\_PAD1\_CSI21\_DY4[20]  
CSI21\_DY4\_PULLTYPESELECT = 0x1
  - csi21\_dx3:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[4]  
CSI21\_DX3\_PULLTYPESELECT = 0x1
  - csi21\_dy3:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX3\_PAD1\_CSI21\_DY3[20]  
CSI21\_DY3\_PULLTYPESELECT = 0x1
  - csi21\_dx2:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY2[4]  
CSI21\_DX2\_PULLTYPESELECT = 0x1
  - csi21\_dy2:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX2\_PAD1\_CSI21\_DY2[20]  
CSI21\_DY2\_PULLTYPESELECT = 0x1
  - csi21\_dx1:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[4]  
CSI21\_DX1\_PULLTYPESELECT = 0x1
  - csi21\_dy1:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX1\_PAD1\_CSI21\_DY1[20]  
CSI21\_DY1\_PULLTYPESELECT = 0x1
  - csi21\_dx0:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[4]  
CSI21\_DX0\_PULLTYPESELECT = 0x1
  - csi21\_dy0:
    - CONTROL\_CORE\_PAD0\_CSI21\_DX0\_PAD1\_CSI21\_DY0[20]  
CSI21\_DY0\_PULLTYPESELECT = 0x1
3. The CSIPHY is initialized and ready/active in CSI2 mode.

### 8.2.3.2.3 ISS CCP2 and Link Initialization Sequence

The CSI2-B interface is expected to coordinate the PHY initialization. The controller must ensure that the PHY is held in RESET state until the CCP transmitter is powered up and the link comes to the defined state. The controller can use the FORCERXMODE signals of CAMERARX for this purpose. FORCERXMODE forces the receiver state-machine into RESET state, while the rest of common logic is powered up and functional. One possible initialization sequence is:

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2-B receiver registers to be ready to receive signals/data from the CSIPHY:
  - (a) Configure all CCP2 registers:
    - (i) Set **CSI2\_COMPLEXIO\_CFG**[2:0] CLOCK\_POSITION.
    - (ii) Set **CSI2\_COMPLEXIO\_CFG**[6:4] DATA1\_POSITION.
  - (b) Set **CONTROL\_CAMERA\_RX**[20:19] CAMERARX\_CSI22\_CAMMODE

#### CAUTION

This must be done before the CSIPHY is active.

- (c) A dedicated internal clock gate control is present for each PHY. Enable or disable the internal

CTRLCLK from the CAMERARX\_CSI22\_CTRLCLKE[21] CAMERARX\_CSI22\_CTRLCLKE bit or the [18] CAMERARX\_CSI21\_CTRLCLKE bit.

2. CSIPHY and link initialization sequence:
  - (a) Deassert the CSIPHY reset:
    - (i) Set [CSI2\\_COMPLEXIO\\_CFG](#)[30] RESET\_CTRL to 0x1.
  - (b) Assert the FORCERXMODE signal:
    - (i) Set [CSI2\\_TIMING](#)[15] FORCE\_RX\_MODE\_IO1 to 0x1.
  - (c) Power up the CSIPHY:
    - (i) Set [CSI2\\_COMPLEXIO\\_CFG](#)[28:27] PWR\_CMD to 0x1.
  - (d) Check that the state status reaches the ON state:
    - [CSI2\\_COMPLEXIO\\_CFG](#)[26:25] PWR\_STATUS = 0x1
  - (e) Release the FORCERXMODE signal:
    - (i) Set [CSI2\\_TIMING](#)[15] FORCE\_RX\_MODE\_IO1 to 0x0.
3. The CSIPHY is initialized and ready/active in CSI1/CCP2B mode.

#### 8.2.3.2.4 ISS CSI PHY Error Signals

In D-PHY mode, the CSIPHY supports the following error detection and signaling to the associated receiver:

- ERRSOTHS: Flags 1-bit errors in the HS start of transmission synchronization pattern. In this error scenario, the CSIPHY continues to receive the data and pass it to the receiver, but confidence in the data may be low, because of the 1-bit error seen in sync. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRSOTSYNCHS: Flags multiple bit errors in the HS start of transmission synchronization pattern. In this case, the CSIPHY cannot achieve proper synchronization and does not pass the received data to the receiver. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRCONTROL: Flags the control sequence error; that is, when the LP sequence observed on line is not recognized as a valid control sequence. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRESC: Flags the escape entry error; that is, when the escape entry sequence is unrecognized. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRSYNDESC: Flags the low-power data transmission synchronization error. This error is flagged if the number of bits received during a low-power data transmission is not a multiple of 8 bits. This signal, if asserted, is high until the next change in the state of the LP line. In case the number of received bits is 1 less than a multiple of 8, RXVALIDESC is also asserted together with ERRSYNDESC, and an erroneous data byte is output on RXDATAESC. In other cases of this error, RXVALIDESC is not asserted and an erroneous data byte is not sent out.

In CCP2 mode, the CSIPHY supports the following error detection and signaling to the associated receiver:

- CCPERRRESYNC output is an error indicator to the receiver to flag the shifted synchronization error, if the new synchronization sequence is not aligned with a 32-bit word boundary compared to the previously received synchronization sequence. This error flag is asserted for 32 cycles (4 bytes/32 bits).

### 8.2.3.3 ISS CSI2 PHY Register Manual

#### 8.2.3.3.1 ISS CSI2 PHY Instance Summary

[Table 8-44](#) lists the ISS CSI2 PHY instance.

**Table 8-44. ISS CSI2 PHY Instance Summary**

Module Name	L3 Base Address	Size
<a href="#">ISS_CAMERARX_CORE1</a>	0x5200 1170	32 bytes
<a href="#">ISS_CAMERARX_CORE2</a>	0x5200 1570	32 bytes

**NOTE:** ISS\_CAMERARX\_CORE1 is for CSI2-A CAMERARX.

ISS\_CAMERARX\_CORE2 is for CSI2-B/CCP2 CAMERARX.

### 8.2.3.3.2 ISS CSI2 PHY Registers

#### 8.2.3.3.2.1 ISS CSI2 PHY Register Summary

[Table 8-45](#) summarizes the ISS CSI2 register mapping.

**Table 8-45. ISS CSI2 PHY Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	ISS_CAMERARX_CORE1 Base Address	ISS_CAMERARX_CORE2 Base Address
<a href="#">REGISTER0</a>	RW	32	0x0000 0000	0x5200 1170	0x5200 1570
<a href="#">REGISTER1</a>	RW	32	0x0000 0004	0x5200 1174	0x5200 1574
<a href="#">REGISTER2</a>	RW	32	0x0000 0008	0x5200 1178	0x5200 1578

#### 8.2.3.3.2.2 ISS CSI2 PHY Register Description

through describe the ISS CSI2 PHY register bits.

## 8.2.4 ISS CCP2

### 8.2.4.1 ISS CCP2 Environment

#### 8.2.4.1.1 ISS CCP2 Protocol and Data Formats

This section describes the CCP2 protocol and data formats. The CCP2 receiver is compatible with the *SMIA CCP2 Specification v1.0* and the *MIPI CSI1 Specification*. [Table 8-52](#) describes the I/O for serial interface CCP2.

**Table 8-52. I/O Description for Serial Interface CCP2**

Signal Name		I/O <sup>(1)</sup>	Description
ccp2_datp	CAM_S_DATA	I	Serial data input. Configurable.
ccp2_datn			
ccp2_strbp	CAM_S_CLK	I	Serial clock or strobe input. Configurable.
ccp2_strbn			

<sup>(1)</sup> I = Input; O = Output

From the device point of view, the CCP2 interface comprises four differential inputs representing two effective signals: the serial data and the clock.

The CCP2 receiver is a serial interface to an image sensor. Signals from the camera are serial input data (CAM\_S\_DATA) and a clock/strobe signal (CAM\_S\_CLK).

#### 8.2.4.1.1.1 ISS CCP2 Synchronization Codes

Each frame is clearly identified by four unique 32-bit synchronization codes: frame start, frame end, line start, and line end, which are embedded in the serial bitstream. The logical channel identification number is also encoded in the synchronization codes.

- Frame-start code (FSC): Identifies the start of a new frame
- Line-start code (LSC): Identifies the start of a new line and is received for every line, except the first line, that starts with an FSC
- Line-end code (LEC): Identifies the end of a line and is received for every line, except the last line, that ends with an FEC
- Frame-end code (FEC): Identifies the end of the last line and the end of the current frame

#### 8.2.4.1.1.2 ISS CCP2 False Synchronization Code Protection

CCP2 supports false synchronization protection (FSP). Additional bytes after the JPEG stream can be written to the SDRAM. They do not prevent JPEG encode and there is no need to preserve them.

#### 8.2.4.1.1.3 ISS CCP2 Image Data Operating Modes and Alignment Constraints

The CCP2 receiver interface has several image data operating modes (see [Table 8-53](#)). The EXP<sub>x</sub> formats (where x = 8, 16, or 32) are used to expand data up to 8, 16, or 32 bits by padding data with zeros. The Data Size Increase in Memory column indicates memory overhead versus format without data expansion and/or DPCM compression.

**Table 8-53. ISS CCP2 Image Data Operating Modes and Alignment Constraints**

CCP2_LCx_CT RL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (When sending data to memory, N/A when sending to VP)	Data Size Increase in Memory. (When negative, data compression present)	2D Mode Availability <sup>(1)</sup>	Comments
0x0	YUV4:2:2 big endian	16	0%	Yes	

<sup>(1)</sup> If 2D mode is available, there are no supplementary constraints on data width. 2D mode does not apply when sending to the video port (VP).

**Table 8-53. ISS CCP2 Image Data Operating Modes and Alignment Constraints (continued)**

<b>CCP2_LCx_CT RL[7:2] Format</b>	<b>CCP2 Data Format</b>	<b>Bits per Pixel (bpp) (When sending data to memory, N/A when sending to VP)</b>	<b>Data Size Increase in Memory. (When negative, data compression present)</b>	<b>2D Mode Availability <sup>(1)</sup></b>	<b>Comments</b>

0x19	RAW12 + EXP16	16	33%	Yes	
0x1A	RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x1B	RAW10 -> RAW8 DPCM	8	-20%	Yes	DPCM decompression
0x1C	JPEG, 8-bit data	N/A	0%	Yes	

**Table 8-53. ISS CCP2 Image Data Operating Modes and Alignment Constraints (continued)**

<b>CCP2_LCx_CTRL[7:2] Format</b>	<b>CCP2 Data Format</b>	<b>Bits per Pixel (bpp) (When sending data to memory, N/A when sending to VP)</b>	<b>Data Size Increase in Memory. (When negative, data compression present)</b>	<b>2D Mode Availability <sup>(1)</sup></b>	<b>Comments</b>
0x1D	JPEG, 8-bit data + FSP	N/A	0%	Yes	
0x1E	RAW10 -> RAW8 DPCM	8	-20%	Yes	Data right shift
0x1F	RAW8 DPCM12-> RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x20	RAW10 -> RAW8 ALAW	8	-20%	Yes	
0x21	RAW8 DPCM10 -> ALAW	8	-20%	Yes	

**NOTE:**

- Padding data of a 32-bit pixel data stream is handled the same way regardless of the programmed format. Therefore, there is no increase or decrease in storage because it is not compressed or decompressed.
- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros

**CCP2\_LCx\_CTRL[15:8] ALPHA** can be used to set an alpha value.

For RGB444 + EXP16:

- data\_out[31:28] = ALPHA [3:0]
- data\_out[15:12] = ALPHA [3:0]

- EXP32 = Data expansion to 32 bits, padding with alpha

**CCP2\_LCx\_CTRL[15:8] ALPHA** can be used to set an alpha value.

For RGB888 + EXP32: data\_out[31:24] = ALPHA [7:0]

- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the video-preprocessing hardware is enabled. Programmers must ensure that only one logical channel is enabled to the video preprocessing hardware. The behavior of the hardware is unpredictable if several logical channels to the video preprocessing hardware are enabled simultaneously.
- DPCM10 = Data decompression to 10 bits. Applies only to RAW6, RAW7, and RAW8 data formats; disabled if **CCP2\_CTRL[4] MODE** = 0.
- Padding is handled the same way regardless of the programmed format.

**NOTE:** Data written by CSI2 can be read back by the CCP2 read channel. Some constraints apply (see [Table 8-56](#)).

#### 8.2.4.1.1.4 ISS CCP2 Pixel Data Format

This section summarizes how the CCP2 pixel data formats are transmitted over the serial interface and how the pixels are reconstructed, stored in memory, or passed to the video port.

The CCP2 receiver can cope with all data formats if the data line length sent through the CS1/CCP2 physical protocol is a multiple of 32 bits. This condition is required for the CCP2 receiver to work correctly.

However, some data formats impose stronger line-length constraints to finish pixel reconstruction correctly at the end of the lines. This is imposed by CCP2 protocol-specific requirements, and not the CCP2 receiver. If CCP2 protocol constraints are not respected:

- Only the pixels reconstructed last in every line are erroneous. The missing bits are replaced with zeros

to perform pixel reconstruction.

- The FW\_IRQ interrupt is triggered.

### 8.2.4.1.1.4.1 ISS CCP2 YUV Operating Modes

**NOTE:** Although there are different possibilities of endianness in the bitstream, the device as a whole typically works in little-endian format. Therefore, the use of little-endian format is recommended.

#### 8.2.4.1.1.4.1.1 ISS CCP2 YUV4:2:2

The YUV4:2:2 data format can be stored to memory in little- or big-endian format. The line length sent through the CCP2 receiver protocol must be a multiple of 32 bits.

YUV4:2:2 data format can also be sent to the video port.

YUV4:2:2 + VP is used to output RAW8 data to the video port: YUV4:2:2 + VP is equivalent to RAW8 + VP. [Figure 8-14](#) and [Figure 8-15](#) show big-endian and little-endian YUV4:2:2 format, respectively. Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x0 to select YUV4:2:2 big-endian mode and to 0x1 for YUV4:2:2 little-endian mode.

**Figure 8-14. ISS CCP2 YUV4:2:2 Big Endian**

Figure 8-15. ISS CCP2 YUV4:2:2 Little Endian

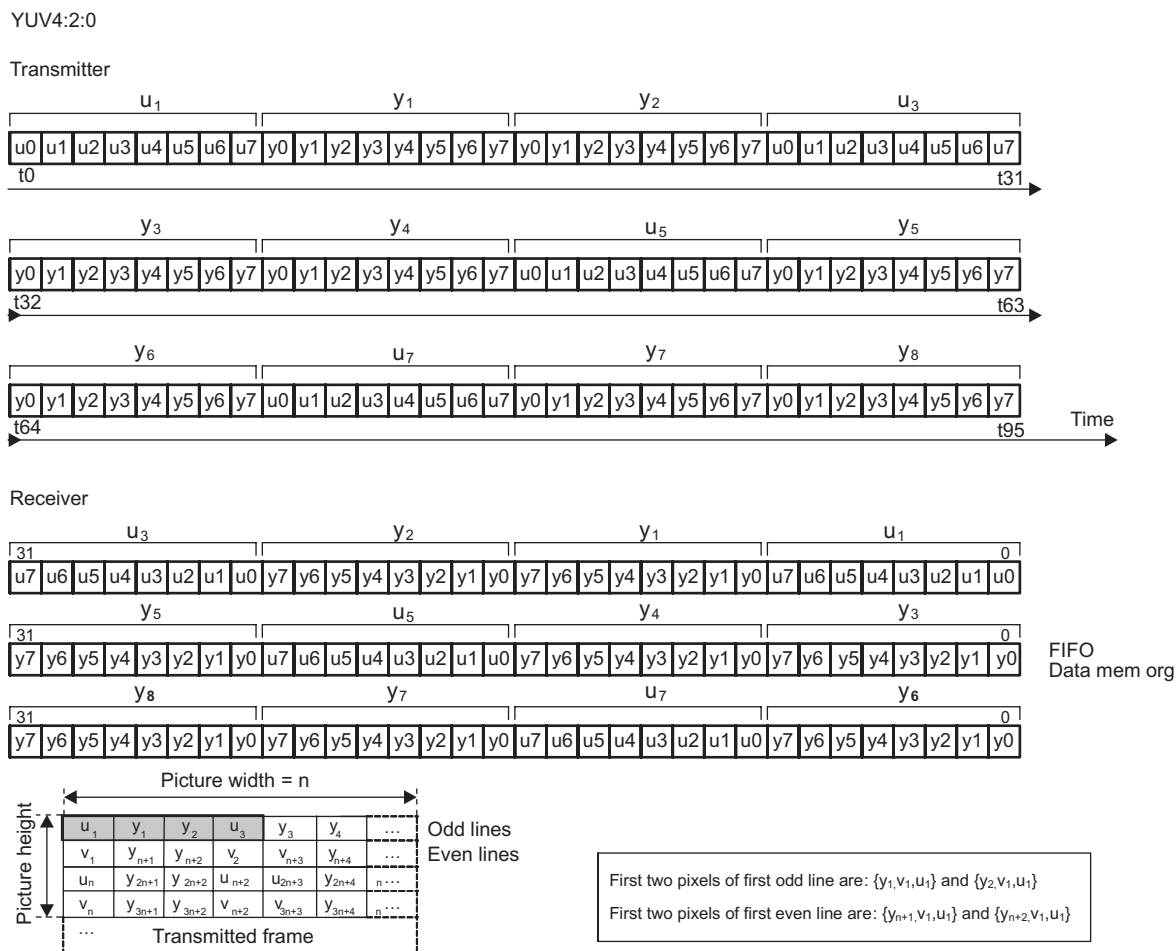

8.2.4.1.1.4.1.2 ISS CCP2 YUV4:2:0

The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. Furthermore, the line length all together sent by the CCP2 receiver is a multiple of 3 x 32 bits and the number of lines is even to correctly finish the pixel reconstruction.

The line structure is different for odd and even lines. Odd lines transport the U component, while even lines contain the V component. This is shown in Figure 8-16. Set CCP2\_LCx\_CTRL[7:2] FORMAT to 0x3 to select YUV4:2:0 mode.

**Figure 8-16. ISS CCP2 YUV4:2:0**

camss-053

### 8.2.4.1.1.4.2 ISS CCP2 RGB Operating Modes

#### 8.2.4.1.1.4.2.1 ISS CCP2 RGB888

RGB888 data format can be output to memory in two formats: without data expansion and with data expansion.

If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The line length all together sent by the CCP2 receiver is a multiple of 3 x 32 bits to finish pixel reconstruction correctly.

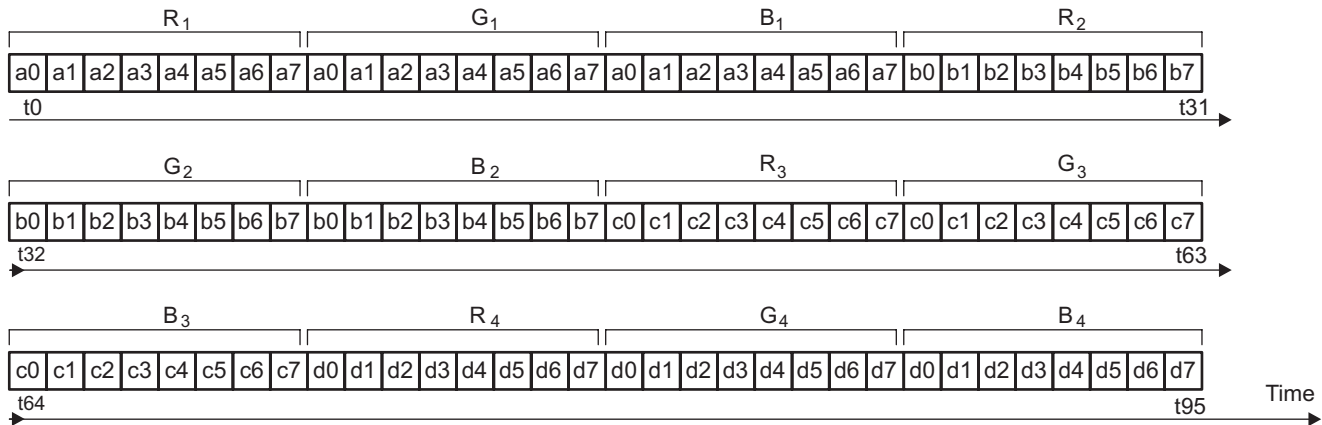

Figure 8-17 is an example of RGB888 format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x6 to select RGB888 mode (24 bits) or to 0x7 to expand RGB888 over 32 bits.

**Figure 8-17. ISS CCP2 RGB888**

RGB888

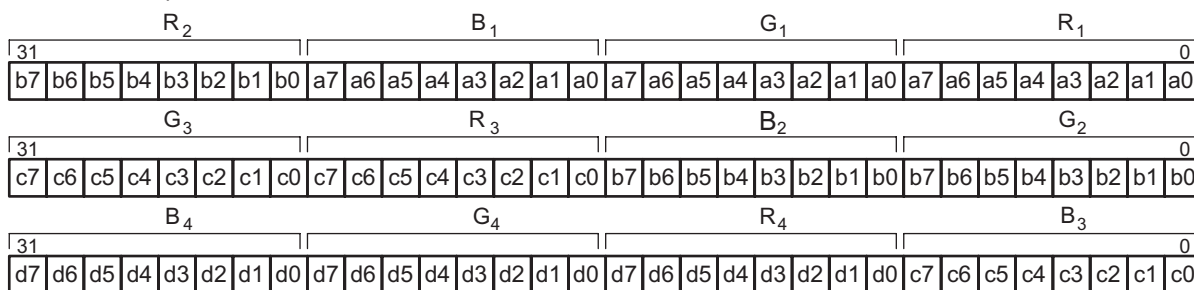

Line width must be a multiple of three 32-bit words.

Transmitter

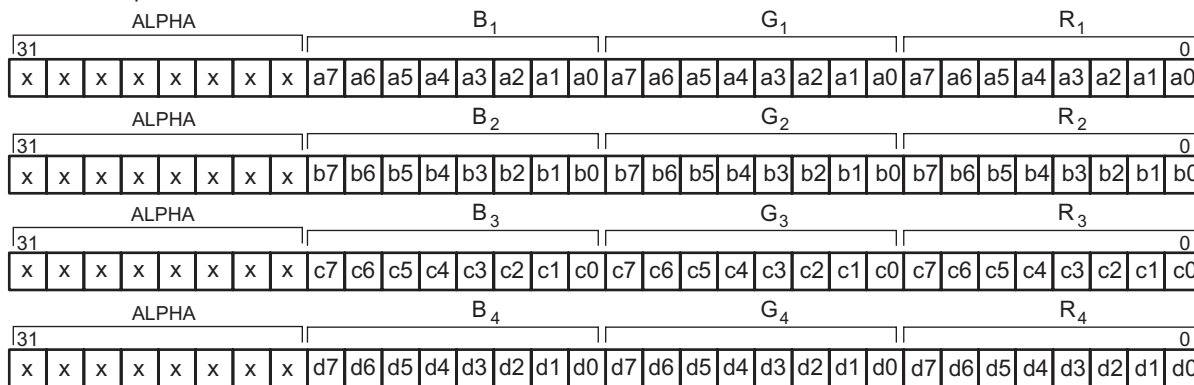

Receiver

Without data expansion

With data expansion

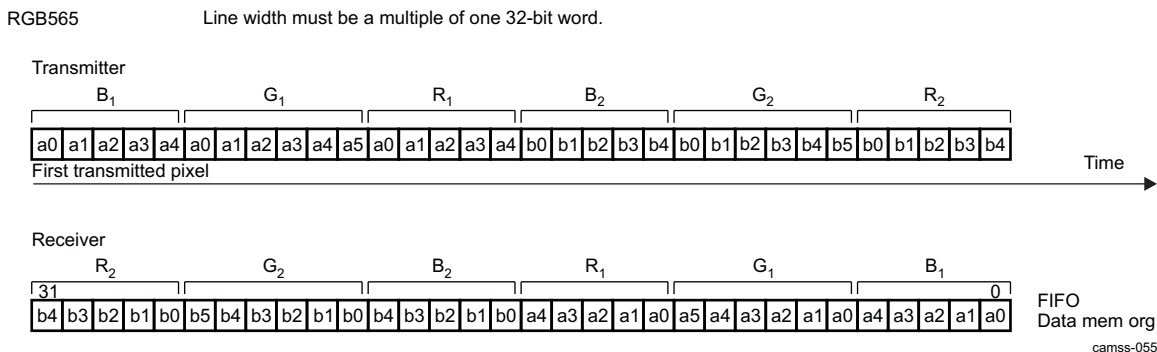

camss-054

### 8.2.4.1.1.4.2.2 ISS CCP2 RGB565

For RGB565, the line length sent through the CCP2 receiver protocol is a multiple of 32 bits (see [Figure 8-18](#)). Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x6 to select RGB565 mode.

**Figure 8-18. ISS CCP2 RGB565**

### 8.2.4.1.1.4.2.3 ISS CCP2 RGB444

RGB444 data format is output to memory with data expansion. If data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits (see [Figure 8-19](#)). Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x4 to select RGB444 mode (12 bits expanded to 16).

**Figure 8-19. ISS CCP2 RGB444**

### 8.2.4.1.1.4.3 ISS CCP2 RAW Bayer Operating Modes

**NOTE:** For more information about packed RAW data, see [Section 8.2.4.3.5.1, ISS CCP2 Read Data From Memory](#).

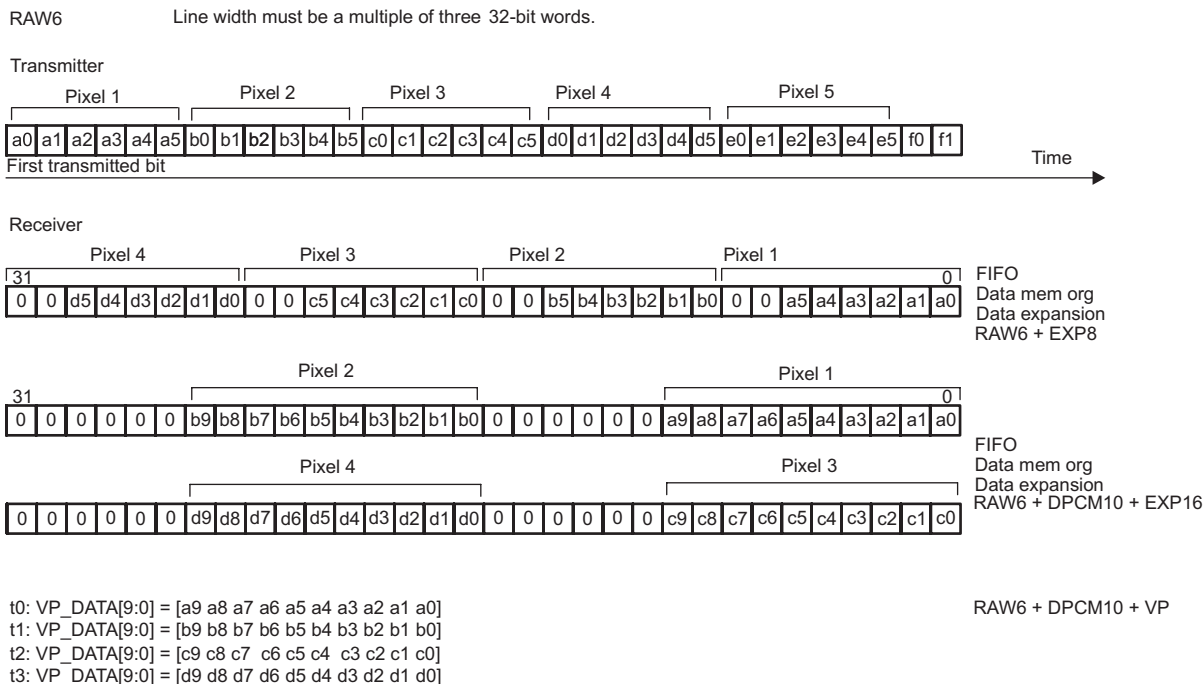

#### 8.2.4.1.1.4.3.1 ISS CCP2 RAW6

RAW6 data format can be output to memory in two formats: without data expansion and with data expansion. The line length sent through the CSI receiver protocol is a multiple of 32 bits. The line all together sent by the CCP2 receiver is a multiple of 3 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 6 is 96; that is, 3 x 32 bits).

[Figure 8-20](#) shows the RAW6 format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to:

- 0x8 to select RAW6 mode expanded to 8-bit
- 0x9 to select RAW6 mode with DPCM decompression
- 10-bit and expansion to 16-bit
- 0xA to select RAW6 mode with DPCM decompression to 10-bit to video port

**Figure 8-20. ISS CCP2 RAW6**

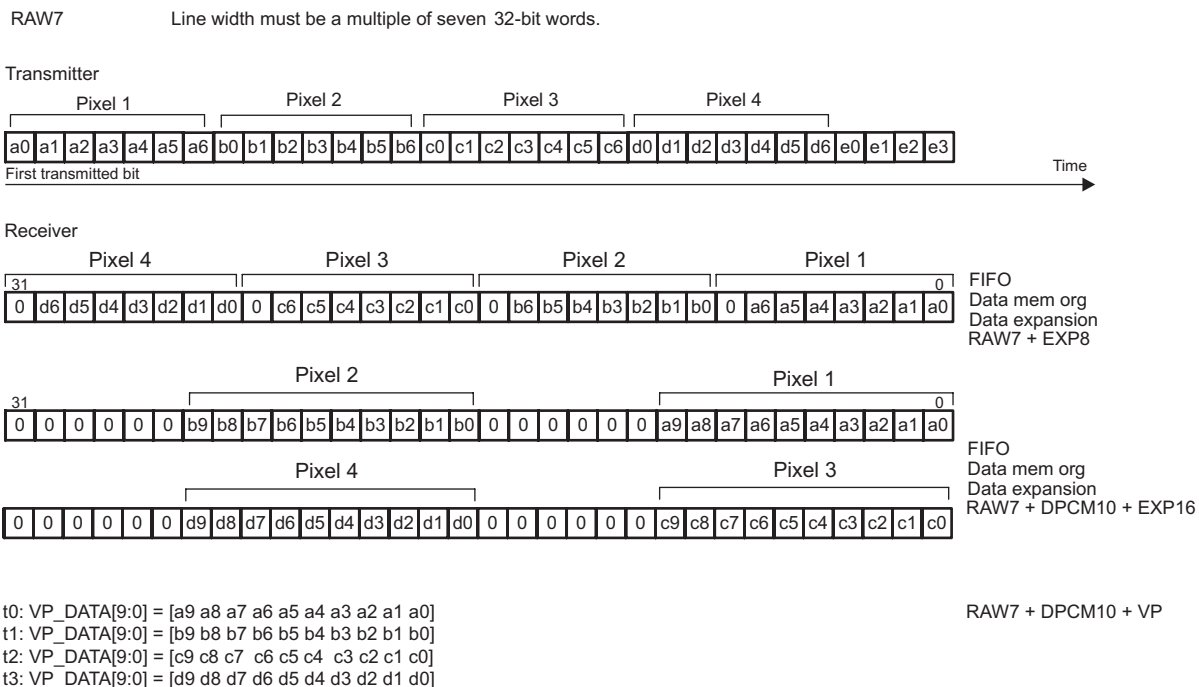

**NOTE:** Use RAW8 data format to output RAW6 data format to memory.

**8.2.4.1.1.4.3.2 ISS CCP2 RAW7**

RAW7 data format can be output to memory in two formats: without data expansion and with data expansion. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The line length all together sent by the CCP2 receiver is a multiple of 7 x 32 bits to finish the pixel reconstruction correctly (the lowest common multiple of 32 and 7 is 224; that is, 7 x 32 bits).

Figure 8-21 shows the RAW7 format. Set CCP2\_LCx\_CTRL[7:2] FORMAT to:

- 0xC to select RAW7 mode expanded to 8-bit
- 0xD to select RAW7 mode with DPCM decompression to 10-bit and expansion to 16-bit
- 0xE to select RAW7 mode with DPCM decompression to 10-bit to video port

**Figure 8-21. ISS CCP2 RAW7**

**NOTE:** Use RAW8 data format to output RAW7 data format to memory.

#### 8.2.4.1.1.4.3.3 ISS CCP2 RAW8

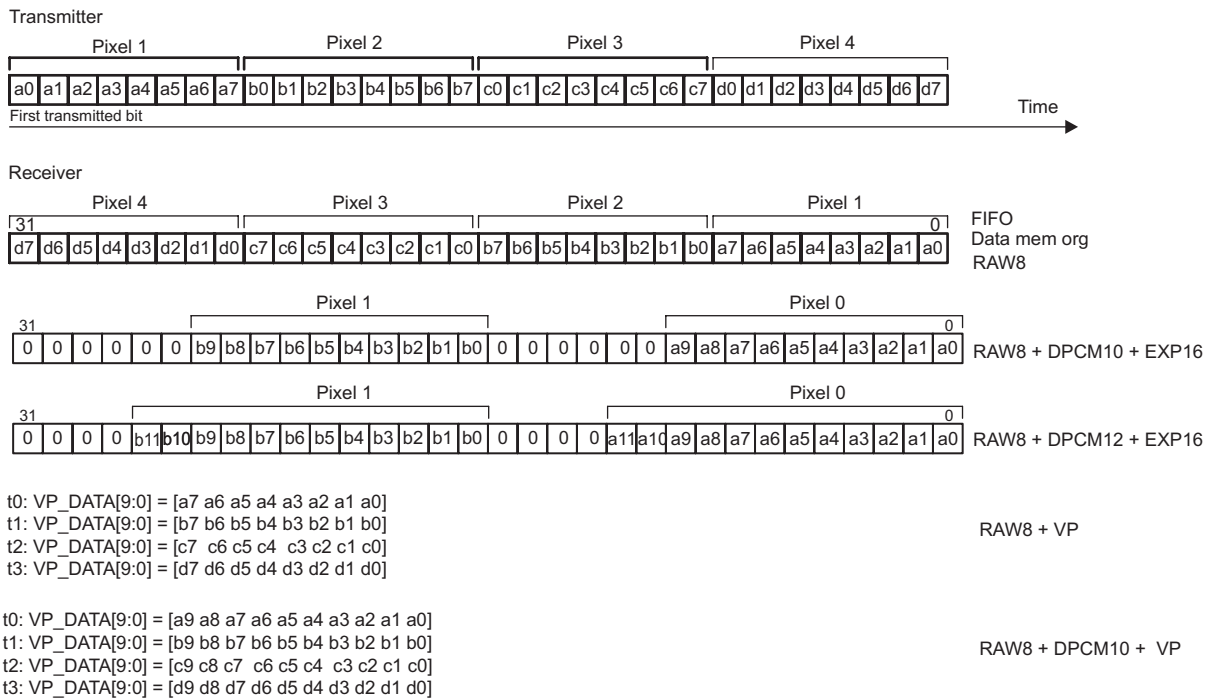

RAW8 data format can be output to memory. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits.

Figure 8-22 shows RAW8 format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to:

- 0x10 to select RAW8
- 0x11 to select RAW8 mode with DPCM decompression to 10-bit and expansion to 16-bit
- 0x12 to select RAW8 mode with DPCM decompression to 10-bit to video port
- 0x20 to select RAW8 with A-Law decompression to RAW10

**Figure 8-22. ISS CCP2 RAW8**

RAW8 Line width must be a multiple of one 32-bit word.

camss-059

**NOTE:** Use YUV4:2:2 + VP to output RAW8 data to the video port: YUV4:2:2 + VP is equivalent to RAW8 + VP.

**8.2.4.1.1.4.3.4 ISS CCP2 RAW10**

RAW10 data format can be output to memory in two formats: without data expansion and with data expansion. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. Furthermore, the line length all together sent by the CCP2 receiver is a multiple of 5 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 10 is 320; that is, 10 x 32 bits).

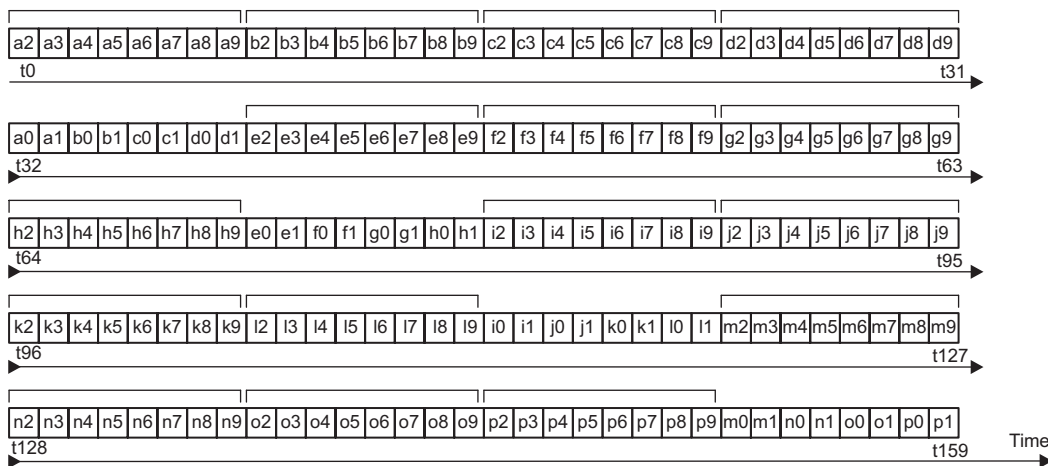

RAW10 data format can be sent to the video port. Figure 8-23 shows the RAW10 format. Set CCP2\_LCx\_CTRL[7:2] FORMAT to:

- 0x14 to select RAW10
- 0x13 to select RAW10 mode with DPCM compression to 7-bit
- 0x16 to select RAW10 mode to video port
- 0x17 with DPCM compression to 7-bit with expansion to 8-bit
- 0x1B to select RAW10 compressed to 8-bit
- 0xB with DPCM compression to 6-bit
- 0xF to select RAW10 compressed to 6-bit with expansion to 8-bit
- 0x1E to select RAW10 compressed to 8-bit
- 0x20 to select RAW10 with A-Law compression to RAW8

**Figure 8-23. ISS CCP2 RAW10**

RAW10 Line width must be a multiple of five 32-bit words.

Data expansion  
RAW10 + EXP16

RAW10 + VP

camss-060

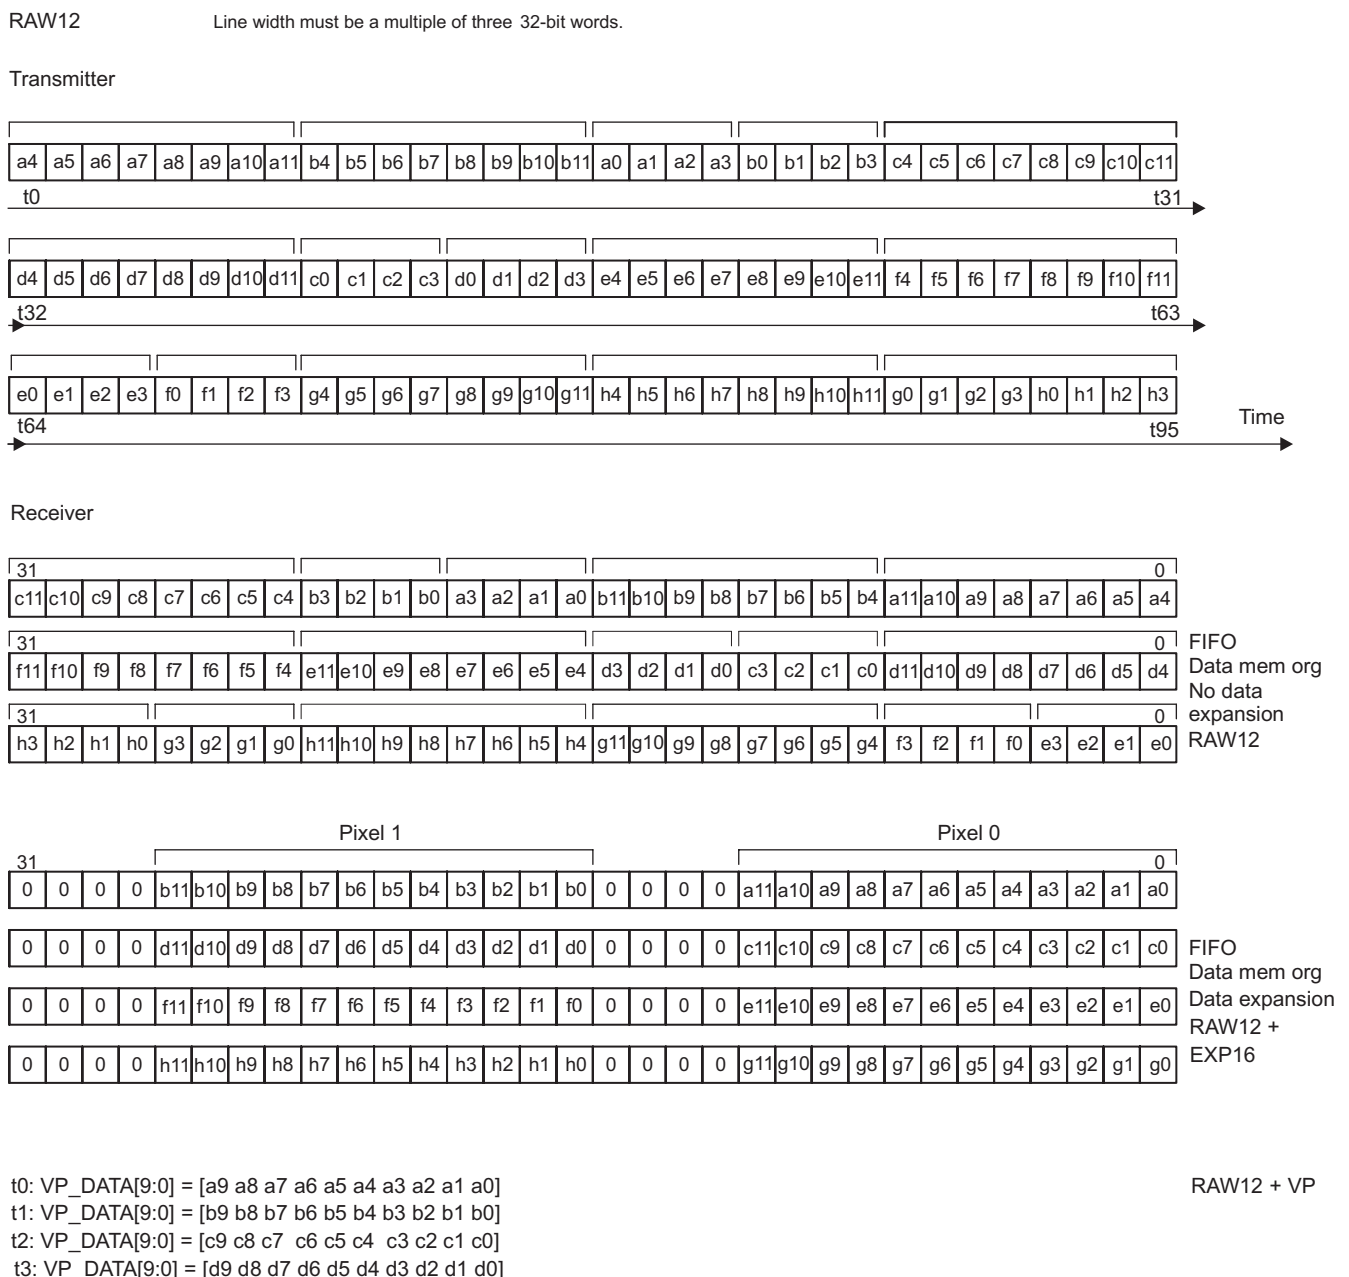

8.2.4.1.1.4.3.5 ISS CCP2 RAW12

RAW12 data format can be output to memory in two formats: without data expansion and with data expansion. If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word. The line length sent through the CCP2 PHY is a multiple of 32 bits. The line length is a multiple of 3 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 12 is 96; that is, 3 x 32 bits).

RAW12 data format can be sent to the video port. Figure 8-24 shows RAW12 format. Set CCP2\_LCx\_CTRL[7:2] FORMAT to:

- 0x18 to select RAW12
- 0x19 to select RAW12 mode with expansion to 16-bit
- 0x1A to select RAW12 mode to video port
- 0x17 with DPCM compression to 7-bit with expansion to 8-bit

Figure 8-24. ISS CCP2 RAW12

#### 8.2.4.1.1.4.4 ISS CCP2 JPEG8 Operating Modes

The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The FSP code insertion on the transmitter side automatically ensures this line length. It is impossible to know in advance the size of a compressed stream. [Figure 8-25](#) shows the JPEG8 and JPEG8 FSP format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x1C to select JPEG8 format, or to 0x1D to select JPEG8 format with FSP.

**Figure 8-25. ISS CCP2 JPEG8 and JPEG8 FSP**

In JPEG8 mode, the JPEG encoder on the sensor side must avoid generating data equal to the synchronization code and must deliver a synchronization-code-free bitstream for line-start and line-end before and after the transmitted data. For more information, see [Section 8.2.4.1.1.2, ISS CCP2 False Synchronization Protection Code](#).

#### 8.2.4.1.1.5 ISS CCP2 Data Transfer Through Write Master Port

The CCP2 receiver module uses its 64-bit master interface to transfer the data stored in the FIFO. The system can set the burst size to be used in the `CCP2_CTRL BURST` register. The recommended burst size is 128 bytes (0x4: 16 x 64-bit bursts are the most efficient for memory output); other sizes should be used only when issues are faced. The module tries to burst data whenever possible to increase system performance and save power. The module uses the appropriate register-selected burst size when the conditions (address is properly aligned, there is enough data in the FIFO to finish the line) are met; otherwise, it uses single requests.

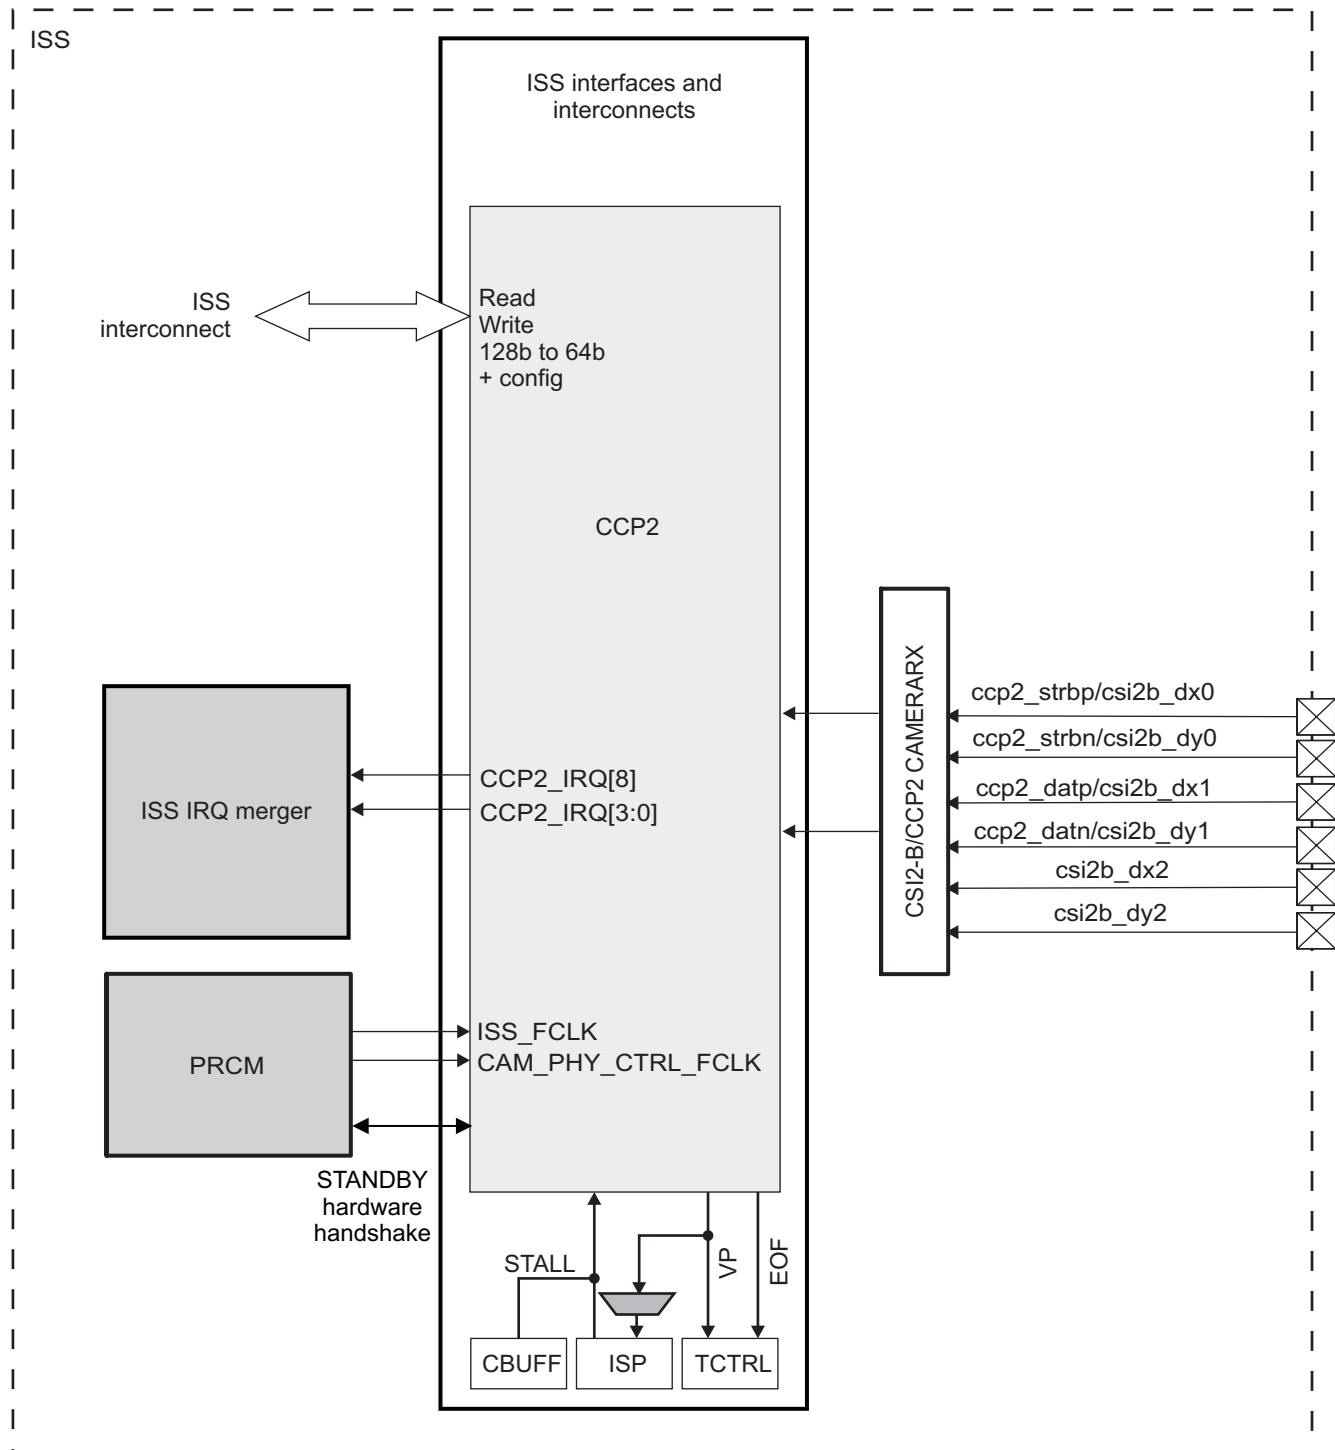

For example, if the line consists of 50 pixels of 64-bit data and `BURST = 0x4` (16 x 64-bit bursts), the module generates four times 16 x 64-bit bursts to transmit the whole line. The FIFO can have information about only two different lines.

The CCP2 engine supports tag count. The count is configurable through a register at the top level of the ISS (see [Section 8.1.3, ISS Register Manual](#)).

#### 8.2.4.2 ISS CCP2 Integration

[Figure 8-26](#) is an overview of the integration of the CCP2 interface in the device. The figure shows the CCP2 receiver top-level block diagram. The CCP2 receiver receives serial data from a CCP2-compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the VP interface (which is connected to the video preprocessing hardware [ISP]) or the ISS interconnect. The CCP2 can also get its data from memory using a dedicated interface read master port when this feature is enabled at compile time.

Figure 8-26. ISS CCP2 Integration

camss-353bu

**NOTE:** Because CCP2 and CSI2-B share pins, they cannot be used simultaneously. For ISP source select, see [Section 8.1.1, ISS Integration](#), for ISP registers input selection and for top-level input select settings.

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

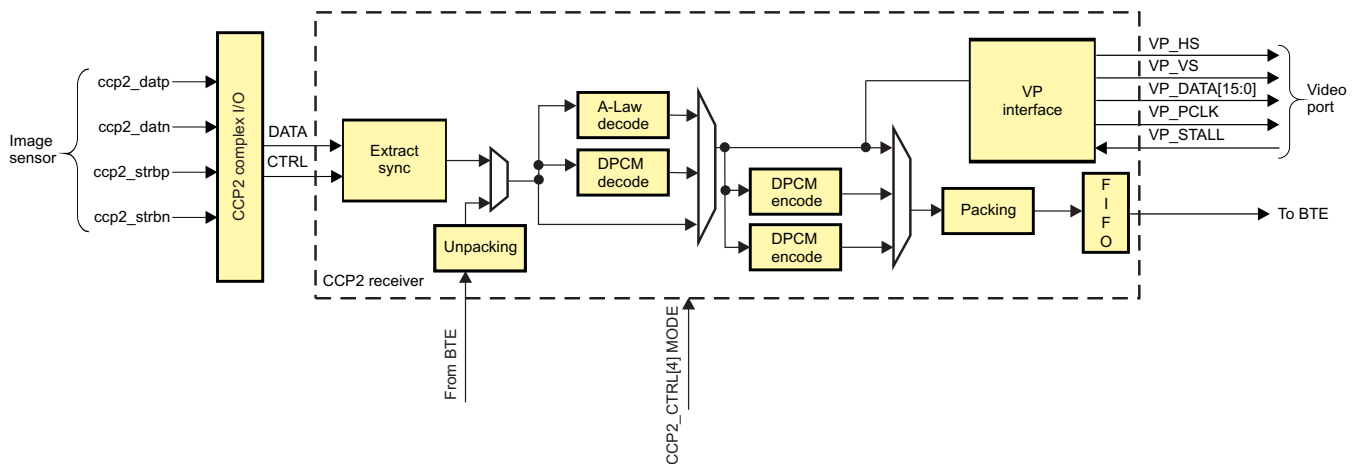

### 8.2.4.3 ISS CCP2 Functional Description

#### 8.2.4.3.1 ISS CCP2 Overview

Figure 8-27 is the top-level block diagram of the CCP2 receiver. The CCP2 receiver receives serial data from a CCP2-compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the VP interface (which is connected to the video preprocessing hardware [ISP]) or the ISS interconnect. The CCP2 can also read data from memory getting burst packets from the BTE when this feature has been enabled at compile time. For read data from memory, see Section 8.2.4.3.5, *ISS CCP2 Memory Read Channel*.

The CCP2 receiver video port interface is connected to the video preprocessing hardware.

**Figure 8-27. ISS CCP2 Receiver Block Diagram**

camss-493

#### 8.2.4.3.2 ISS CCP2 PHY

The CCP2 receiver does not connect directly to a sensor (see Section 8.2.3, *ISS CSI2 PHY*). It uses a complex I/O physical layer. The CCP2 complex I/O is shared with the CSI2-B receiver. The CSI2-B/CCP2 PHY is powered up by configuring the CSI2 receiver configuration register. For more information about the configuration of the PHY, see Section 8.2.3.2.1, *ISS CSI2 PHY Functional Configuration*. The CCP2 serial interface is a unidirectional differential serial interface with two options for the PHY: data/clock or data/strobe signals. After the PHY is configured and initialization is done, the CCP2 mode can be selected and controlled by the `CCP2_CTRL[1] MODE` bit.

##### 8.2.4.3.2.1 ISS CCP2 Data/Clock Signaling

Data/clock signaling consists of two parallel signals: data and data clock.

- The data signal carries bit serial data. The CCP2 transmitter writes the data on each falling edge of the clock. The data are usually transmitted byte-wise, least-significant bit (LSB) first.
- The data clock signal carries the clock signal. The CCP2 transmitter writes the data on each falling edge of the clock. The CCP2 receiver reads the data on the rising edge of the clock.

##### 8.2.4.3.2.2 ISS CCP2 Data/Strobe Signaling (CCP2 Only)

Data/strobe signaling consists of two parallel signals: data and data strobe.

- The data signal carries bit serial data.
- The data strobe signal carries the strobe signal. It toggles when the data signal does not change state.

The data signal or the strobe signal changes between 2 data bits. The data and strobe signals must not change simultaneously. The data and strobe signals are used in the receiver to reconstruct the transmission clock. Both fronts of the reconstructed clock are used to sample the data. Set the [CCP2\\_CTRL\[4\] MODE](#) bit and see [Section 8.2.3, ISS CS/2 PHY](#), to set the data/clock or data/strobe function.

### 8.2.4.3.3 ISS CCP2 VP Interface

[Table 8-54](#) summarizes the video interface signals. The video interface connects the CCP2 receiver module to the video preprocessing hardware (ISP). The interface is connected to a 16-bit video port. On the other side of the video port is the ISIF inside the ISP. The ISIF also uses the signals listed in [Table 8-54](#) to synchronize pixel data sent to it by the CCP2 receiver.

**Table 8-54. ISS CCP2 Video interface Signals**

Pin	Type <sup>(1)</sup>	Description
VP_HS	O	Line trigger output signal
VP_VS	O	Frame trigger output signal
VP_DATA[15:0]	O	Parallel output data: bits 0 to 15
VP_PCLK	O	Video port pixel clock. The frequency can be configured.
VP_STALL	I	Stalls data flow when data is read from memory

<sup>(1)</sup> I = Input; O = Output

When data is read from memory and sent to the video port, the data flow can be stalled by asserting the VP\_STALL signal. Doing so does not overflow internal FIFOs: the CCP2 module adapts its read rate automatically.

The response time to the VP\_STALL signal must not exceed two cycles: when VP\_STALL is asserted, the CCP2 module can send 0, 1, or 2 pixels to the video port.

VP\_STALL is asserted and deasserted synchronous to the functional clock.

---

**NOTE:** Stalling the video port for data received from the sensor may lead to internal overflows; VP\_STALL must not be used for this purpose.

---

The pixel clock is generated from the functional clock. Clock pulses are gated based on the selected clock division factor and pixel availability. In other words, software must set the CCP2 receiver to ensure that the pixel clock:

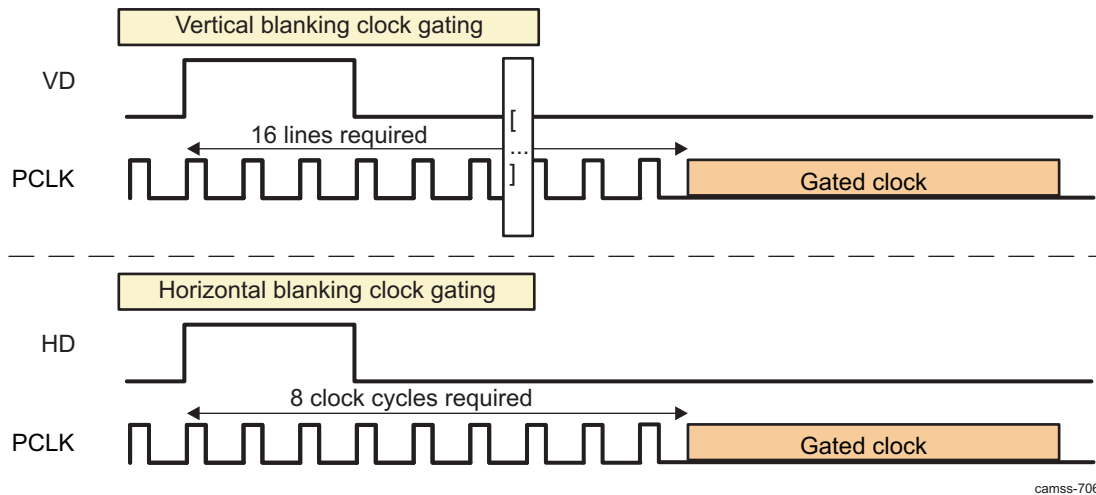

- Never exceeds what the ISP can support: the top value set in the [CCP2\\_CTRL\[31:15\] FRACDIV](#) bit field
- Is sent only when valid pixels or blanking data must be sent

Also, software must set the number of clock pulses during horizontal blanking periods using the [CCP2\\_CTRL1\[1:0\] BLANKING](#) bit field.

- The CCP2 receiver stops generating horizontal blanking clock pulses when the number of pulses defined in the [CCP2\\_CTRL1\[1:0\] BLANKING](#) bit field are generated or when data for the next line arrives from the sensor.
- Free-running horizontal blanking can be selected only when data comes from the sensor.
- When data comes from memory, the CCP2 receiver ensures that the number of horizontal blanking pulses defined in the [CCP2\\_CTRL1\[1:0\] BLANKING](#) bit field is received. The CCP2 receiver stops generating horizontal blanking clock pulses when then number of pulses defined in the [CCP2\\_CTRL1\[1:0\] BLANKING](#) bit field is generated or when data for the next line arrives from the sensor.

**NOTE:** To work properly, the ISP requires a minimum of eight clock cycles in the horizontal blanking period and a minimum of 16 lines in the vertical blanking period. The pixel clock can be gated only when these intervals are respected. This is required to flush the pipeline of the different ISP modules. Figure 8-28 shows VP\_PCLK gating during blanking periods.

**Figure 8-28. ISS CCP2 VP\_PCLK Gating During Blanking Periods**

Vertical blanking generation is controlled through the `CCP2_CTRL[9] VP_CLK_FORCE_ON` bit. The VP\_PCLK clock is enabled during vertical blanking periods when this bit is set. This pushes pixels through the ISP processing pipe. It is needed, for example, when the ISP resizer uses the averager. Otherwise, hardware ensures only that at least four clock pulses are generated before the first pixel of each frame. It may be necessary for the clock to keep running after the frame end to flush internal pipelines. In that case, an interrupt request (IRQ) or status bit is typically present in the attached hardware that indicates when the VP\_PCLK clock is no longer needed (for example, an end of processing interrupt). The module leaves the vertical blanking state when new data is received from the sensor or the memory read channel.

The configured pixel clock is used for active and blanking periods.

Table 8-55 shows how RAW and YUV data is sent over the video port. The data is sent to the ISIF if ISP is used. For the ISIF details about video port data, see Section 8.3 *ISS: ISP*.

**Table 8-55. ISS CCP2 Video Port Data Mapping**

Format	Video Port DATA[15:0]

#### 8.2.4.3.4 ISS CCP2 Data Compression

The data compression technique used is DPCM and pulse code modulation (PCM).

The CCP2 receiver performs on-the-fly compression and decompression. The compressed/decompressed data is passed to the video preprocessing hardware or stored in memory.

The data compression method is lossy and does not require any information outside the current encoded/decoded line. This means that all the image lines can be encoded and decoded separately.

Two different predictors are used:

- The simple predictor  
This predictor uses only the previous same color component value as a prediction value. Therefore, only 2-pixel memory is required.
- The advanced predictor  
This predictor uses four previous pixel values, when the prediction value is evaluated. This means that also the other color component values are used, when the prediction value is defined.

The preferable use is that the simple predictor is used with 10 bits to 8 bits or 12 bits to 8 bits conversion (10810 or 12812) and the advanced predictor is used with 10 bits to 7 bits and 10 bits to 6 bits conversions (10710 and 10610). The advanced predictor gives slightly better prediction for pixel value; thus, the image quality can be improved with it. Because the simple predictor is very simple, the processing power and memory requirements are reduced with it, when the image quality is already high enough.

Select the predictor with the [CCP2\\_LCx\\_CTRL\[10\]](#) DPCM\_PRED bit.

#### 8.2.4.3.5 ISS CCP2 Memory Read Channel

The memory channel can perform the following operations:

- Reads data from memory. It is unpacked and DPCM or A-Law decompressed if necessary.
- Sends data to the video preprocessing hardware
- Sends data back to memory. It can be DPCM or A-Law compressed and packed before it is sent to memory.

It cannot receive its input data directly from the sensor, and the logical channels are disabled when the memory channel is enabled.

[Table 8-56](#) summarizes supported modes for memory-to-memory operations.

---

**NOTE:** Video port and memory destinations are mutually exclusive.

8.2.4.3.5.1 ISS CCP2 Read Data From Memory

Figure 8-29 shows the data organization in memory.

Figure 8-29. ISS CCP2 Data Organization in Memory

The user chooses the start address and the line length using the [CCP2\\_LCM\\_SRC\\_ADDR](#) and [CCP2\\_LCM\\_SRC\\_OFST](#) registers. The image start address normally must point to the beginning of a line because of packing constraints. However, it does not necessarily point to the first line of the frame in memory. The [CCP2\\_LCM\\_VSIZE\[27:16\]](#) COUNT bit field specifies the total line count to be read from memory.

It is also possible to skip a certain pixel count ([CCP2\\_LCM\\_HSIZE\[11:0\]](#) SKIP) from the start of the line. Thus, they are not sent to the video port or back to memory. The [CCP2\\_LCM\\_HSIZE\[27:16\]](#) COUNT bit field specifies the horizontal size of the image. The pixels after the right boundary of the image are not read from memory.

When data are sent to the video port, throughput is imposed by the selected VP\_PCLK. Otherwise, it is imposed by the selected interconnect read port clock. The interconnect read rate can be throttled (limiting the maximum data read speed for memory-to-memory operation) using the [CCP2\\_LCM\\_CTRL\[4:3\]](#) READ\_THROTTLE bit field. Therefore, it is possible to read the unused data at a higher rate than the used video port data rate. This provides better performance than framing the image in the video preprocessing hardware.

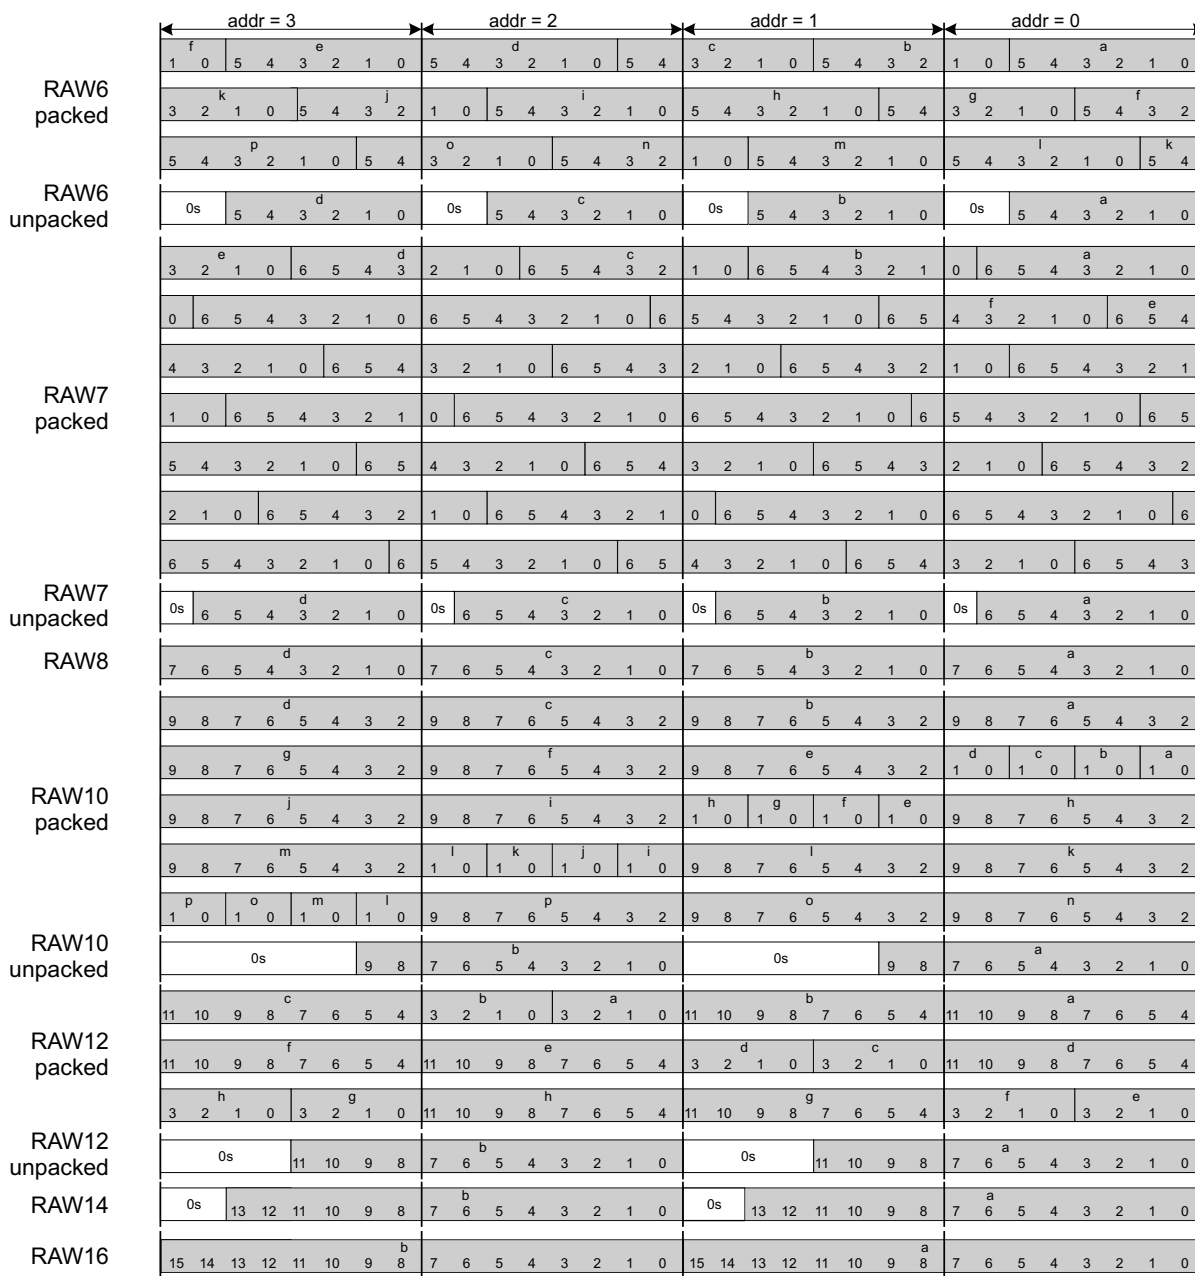

The data storage format in memory is defined by the [CCP2\\_LCM\\_CTRL\[18:16\]](#) SRC\_FORMAT and [CCP2\\_LCM\\_CTRL\[23\]](#) SRC\_PACK bit fields.

Not all I/O format combinations are valid. For more information, see [Table 8-56](#) and [Table 8-57](#).

[Figure 8-30](#) shows how data are packed in memory. Pixel order (left to right in the image) is alphabetical (a, b, c). Therefore, data storage is little endian.

**Figure 8-30. ISS CCP2 Data Organization Packing in Memory**

camss-506u

Table 8-58 summarizes the storage reduction versus unpacked format and image width restrictions when data packing is used. The image width applies to the data width multiple in pixels that must be stored to have storage reduction. Moreover, because each address is 8 bits long, the percentage shows how many bits out of 8 are to be packed in the empty space from another pixel address. A pixel is selected and split. One of the parts is put into another pixel address empty space. When unpacked, each pixel bit is stored continuously again.

**Table 8-58. ISS CCP2 Data Packing Benefit and Constraints**

	Bits Per Pixel		Storage Reduction	Width Multiple (Pixels)
	Packed	Unpacked		
RAW6	6	8	25%	16
RAW7	7	8	13%	3

**Table 8-58. ISS CCP2 Data Packing Benefit and Constraints (continued)**

	Bits Per Pixel		Storage Reduction	Width Multiple (Pixels)
	Packed	Unpacked		
RAW8	8	8	0%	4
RAW10	10	16	38%	16
RAW12	12	16	25%	8

**8.2.4.3.5.2 ISS CCP2 Memory Read Port Burst Generation**

Hardware always uses the largest possible burst size according to the setup. The amount of data read from memory can be higher than what is actually used by the CCP2 receiver. Only full 64-bit burst words are read back from memory. [Figure 8-31](#) shows the data organization and the relationship between the different parameters controlling the burst generation.

**Figure 8-31. ISS CCP2 Data Organization in Memory**

**NOTE:**

- A minimum burst size of 2 must be selected for correct operation.
- The HWORDS bit field must be even for correct operation.

The `CCP2_LCM_SRC_ADDR` register address of the first data to read is aligned to a 32-byte boundary. The read port fetches `CCP2_LCM_PREFETCH[15:3] HWORDS` of 64-bit words per line using the longest possible burst computed from the `CCP2_LCM_CTRL[7:5] BURST_SIZE` bit field and the remaining data to be fetched. Burst size of 128 bytes is preferred. When the CCP2 receiver is configured to fetch more data than required, extra data are dropped internally.

**8.2.4.3.5.3 ISS CCP2 MFLAG Mechanism and Arbitration**

The MFLAG mechanism allows a dynamic increase of the priority of CCP2 real-time traffic, when required, based on the fullness of the CCP2 DMA read and write buffers. Programmable buffer thresholds indicate when the local MFLAG signal is generated. The MFLAG signal is then provided to the L3 interconnect for granting or prioritizing OCP requests. The out band CCP2 MFLAG signal is asynchronous to any ongoing OCP transaction. The threshold corresponds to the fullness of the DMA buffer, and is defined by the following threshold parameters:

- High threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted). The value is set in the `CCP2_CTRL1[30:24] LEVH` register.

- Low threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted). The value is set in the [CCP2\\_CTRL1\[22:16\]](#) LEVL register.

#### 8.2.4.3.5.4 ISS CCP2 Video Port

The video port always receives unpacked data. It can be enabled using the [CCP2\\_LCM\\_CTRL\[2\]](#) DST\_PORT bit. Its clock can be selected with the [CCP2\\_CTRL\[31:15\]](#) FRACDIV bit field and gated or not during frame blanking periods using the [CCP2\\_CTRL\[9\]](#) VP\_CLK\_FORCE\_ON bit.

The data format used by the video port is defined by the [CCP2\\_LCM\\_CTRL\[26:24\]](#) DST\_FORMAT bit field. For a list of supported modes, see [Table 8-57](#).

#### 8.2.4.3.5.5 ISS CCP2 Encode, Pack, and Store Data

This stage is used only when data are sent to memory. Memory destination is selected using the [CCP2\\_LCM\\_CTRL\[2\]](#) DST\_PORT bit. The output data format is defined by the [CCP2\\_LCM\\_CTRL\[26:24\]](#) DST\_FORMAT bit field and the [CCP2\\_LCM\\_CTRL\[31\]](#) DST\_PACK bit. Not all possible combinations are supported; see [Table 8-56](#) for details.

The destination address and offset for the output data of the memory channel are set by the [CCP2\\_LCM\\_DST\\_ADDR](#) and [CCP2\\_LCM\\_DST\\_OFST](#) registers.

Because of alignment constraints on the interconnect port, the output image width restrictions in [Table 8-59](#) apply.

**Table 8-59. ISS CCP2 Output Width Restrictions in Memory-to-Memory Operation**

Format	Bits per Pixel	Width Multiple of <sup>(1)</sup>	Note
RAW6	8	1	Full 32-bit words are written at the end of the line. This last word can eventually include 0s.
RAW6 packed	6	1	
RAW7	8	1	
RAW7 packed	7	1	
RAW8	8	1	
RAW10	16	1	
RAW10 packed	10	16	
RAW12	16	1	Same constraints as RAW8
RAW12 packed	12	8	

<sup>(1)</sup> In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

For example, when RAW6 packed data are written to memory, any output width is allowed. However, only full 32-bit words are written to memory. This eventually overwrites some data in memory at the end of a line.

The supported output width is restricted for packed RAW10 and RAW12 data because of the particular bit ordering in those formats (see [Figure 8-30](#)).

When the DST\_OFST bit is set to 0, start of lines are aligned on 4-byte boundaries. When DST\_OFST is not set to 0, data are aligned on 32-byte boundaries.

---

**NOTE:** The RAW6, RAW7, and DPCM data formats do not apply to the MIPI CSI1-compatible mode.

---

#### 8.2.4.3.5.6 ISS CCP2 DPCM Decompression History

The DPCM compression algorithm can encode the difference between consecutive samples in a line instead of the actual samples value to reduce the amount of data to store. The drawback is that lines must always be decoded from the beginning (the first samples of a line are always encoded as PCM).

The CCP2 receiver has a mechanism to preserve the DPCM decode history for each line to avoid decoding the same samples multiple times when vertical frame division mode is used.

The typical use case (also known as vertical frame division mode) is when an image is wider than the ISP can process on the fly, but the image must be processed. Therefore, the image is cut into multiple vertical slices that are processed sequentially by the ISP. The slices are stitched together in the SDRAM after ISP processing through proper address generation in the ISP. Because of various alignment constraints in the ISP, the slices sent to ISP must overlap. Without preserving the DPCM history, all lines from the beginning of the second (and other consecutive) vertical slice would have to be recoded, which would lead to performance degradation.

Writing DPCM history information into the system memory is enabled by setting the [CCP2\\_LCM\\_HISTORY\[16\] EN\\_HIST\\_WR](#) bit. The [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT](#) bit field defines the position at which history data is written to memory. The position is counted from the beginning line. The first decoded pixel has position 0. The last decoded pixel has position [CCP2\\_LCM\\_HSIZE\[14:0\] SKIP + CCP2\\_LCM\\_HSIZE\[30:16\] COUNT - 1](#). The [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT](#) bit field is used to choose the resume position and allows support of overlapping vertical slices. History data is written to the SDRAM at  $ADDR = \text{CCP2\_LCM\_DST\_ADDR}[31:5] ADDR + Y \times 8$  bytes (where Y is the line number). The CCP2 receiver always writes 8 bytes of history data per line to the SDRAM regardless of the chosen DPCM format. The CCP2 receiver uses the interface bursts to send history data to memory.

DPCM history data holds the decoded value of four samples. The CCP2 receiver exports samples of positions:

- [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT - 3](#)
- [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT - 2](#)
- [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT - 1](#)
- [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT](#)

Every sample is coded on 16 bits, and several MSBs are unused. The valid range for [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT](#) is  $[3.. \text{CCP2\_LCM\_HSIZE}[14:0] \text{SKIP} + \text{CCP2\_LCM\_HSIZE}[30:16] \text{COUNT} - 1]$ . History data can be exported even when data is not sent to the video port or ISS interconnect port (that is, [CCP2\\_LCM\\_HISTORY\[15:0\] HIST\\_EXPORT < CCP2\\_LCM\\_HSIZE\[14:0\] SKIP](#) is valid).

#### 8.2.4.4 ISS CCP2 Programming Model

This section describes the programming model of the CCP2 receiver.

##### 8.2.4.4.1 ISS CCP2 Programming Hardware Setup/Initialization

This section discusses the configuration of the CCP2 receiver required before image capture can begin. Before using the receiver, a CSIPHY initialization in CCP2 mode must be made for CSI2-B/CCP2 CAMERARX, which is associated with the CCP2 receiver. See [Section 8.2.3.2.3, ISS CCP2 and Link Initialization Sequence](#).

---

**NOTE:** The setup/initialization previously explained is valid only when the external sensor is used. If the user plans to use the logical memory channel (LCM) or debug mode ([CCP2\\_CTRL\[13\] DBG\\_EN = 0x1](#)) instead of the external sensor, this setup/initialization is not necessary.

---

##### 8.2.4.4.1.1 ISS CCP2 Reset Behavior

On hardware or software reset of the ISS, all registers in the CCP2 receiver are reset to their reset values.

The two sources for CCP2 software reset are:

- Global reset for the whole ISS – [ISS\\_HL\\_SYSCONFIG\[0\] SOFTRESET](#) bit
- Local reset, affecting only the CCP2 module. The reset is initiated by writing 0x1 in the [CCP2\\_SYSCONFIG\[1\] SOFT\\_RESET](#) bit. The reset done status can be check by reading the [CCP2\\_SYSSTATUS\[0\] RESET\\_DONE](#) bit.

#### 8.2.4.4.2 ISS CCP2 Programming Event and Status Checking

When an event occurs, the corresponding bit in the [CCP2\\_LC01\\_IRQSTATUS](#), [CCP2\\_LC23\\_IRQSTATUS](#), or [CCP2\\_LCM\\_IRQSTATUS](#) register is set. Each event can be individually masked using the [CCP2\\_LC01\\_IRQENABLE](#), [CCP2\\_LC23\\_IRQENABLE](#), or [CCP2\\_LCM\\_IRQENABLE](#) register. Masked events are not transmitted to the interrupt line, but the [CCP2\\_LC01\\_IRQSTATUS](#), [CCP2\\_LC23\\_IRQSTATUS](#), or [CCP2\\_LCM\\_IRQSTATUS](#) register is updated.

Events transmitted to the ISS interrupt merger can be mapped to the Cortex-A9 or Cortex-M3 MPU subsystem or DSP by unmasking [ISS\\_HL\\_IRQENABLE\\_SET\\_i\[\] CCP2\\_IRQj](#) (where  $i = 0$  to  $5$ ,  $j = 0, 1, 2, 3$ , and  $8$ ). Only the [ISS\\_HL\\_IRQENABLE\\_SET\\_5](#) output line is connected to the Cortex-A9 MPU interrupt controller, and only the [ISS\\_HL\\_IRQENABLE\\_SET\\_4](#) output line is connected to the DSP interrupt controller. The Cortex-M3 interrupt controller, however, is connected to all six output lines of [ISS\\_HL\\_IRQENABLE\\_SET\\_i](#) (where  $i = 0$  to  $5$ ). To clear an event, the following actions are required:

- Clear the event at the CCP2 receiver level by writing 1 to the corresponding bit in the [CCP2\\_LC01\\_IRQSTATUS](#), [CCP2\\_LC23\\_IRQSTATUS](#) or [CCP2\\_LCM\\_IRQSTATUS](#) register.
- Events generated by the submodules and ISS top level clear it. Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the [ISS\\_HL\\_IRQENABLE\\_SET\\_i](#) register. It is disabled by setting the appropriate bit in the [ISS\\_HL\\_IRQENABLE\\_CLR\\_i](#) register. When an event occurs, the corresponding bit in the [ISS\\_HL\\_IRQSTATUS\\_i](#) register is set, regardless of whether or not the event is enabled. Bits in the [ISS\\_HL\\_IRQSTATUS\\_i](#) registers are set only when an enabled event occurs. Software can clear a pending [HS\\_VS\\_IRQ](#) event by setting the appropriate bit [ISS\\_HL\\_IRQSTATUS\[17\] HS\\_VS\\_IRQ](#). Events generated by submodules are automatically cleared at ISS top level when they are cleared at submodule level.

#### 8.2.4.4.3 ISS CCP2 Programming Register Accessibility During Frame Processing

There are two types of register accesses in the CCP2 receiver:

- Shadowed registers:
  - These registers/fields can be read and written (if the field is writable) at any time. However, written values take effect only at the start of a frame. Reads return the most-recent write, even though the settings are not used until the next start of frame.
  - The shadowed registers are:
    - [CCP2\\_LCx\\_CTRL](#)
    - [CCP2\\_LCx\\_CODE](#)
    - [CCP2\\_LCx\\_STAT\\_START](#)
    - [CCP2\\_LCx\\_STAT\\_SIZE](#)
    - [CCP2\\_LCx\\_SOF\\_ADDR](#)
    - [CCP2\\_LCx\\_EOF\\_ADDR](#)
    - [CCP2\\_LCx\\_DAT\\_SIZE](#)
    - [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#)
    - [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#)
    - [CCP2\\_LCx\\_DAT\\_OFST](#)
- Busy-locked registers:
  - These registers/fields must not be written if the module is busy.
  - All register fields not listed as shadowed are busy-writable registers.

#### 8.2.4.4.4 ISS CCP2 Programming Enable/Disable the Hardware

The CCP2 receiver is globally controlled by the [CCP2\\_CTRL](#) register. The bit fields in this register must not be modified when the CCP2 interface is active (except [CCP2\\_CTRL\[0\] IF\\_EN](#)).

[Table 8-60](#) and [Table 8-61](#) list the procedures to enable and disable, respectively, the interface.

**Table 8-60. ISS CCP2 Interface Enable**

Step	Bit Field	Value
Clear the interface. Data acquisition starts on the following FSC synchronization code.	CCP2_CTRL[0] IF_EN	0x1
Reset the output FIFO of the module; the reset is caused by the 0-to-1 edge transition.	CCP2_CTRL[0] IF_EN	0x1

**Table 8-61. ISS CCP2 Interface Disable**

Step	Bit Field	Value
Disable interface. <ul style="list-style-type: none"> <li>The interface is disabled immediately if CCP2_CTRL[3] FRAME = 0x0.</li> <li>If CCP2_CTRL[3] FRAME = 0x1 and CCP2_LCx_CTRL[2] CRC_EN = 0x0, the interface is disabled after the FEC synchronization code is received.</li> <li>If CCP2_CTRL[3] FRAME = 0x1 and CCP2_LCx_CTRL[2] CRC_EN = 0x1, the interface is disabled only after the 16-bit CRC checksum and 16-bit pad data is received.</li> <li>Before disabling the interface (IF_EN = 0), it is advised to disable all active channels by writing CCP2_LCx_CTRL[0] CHAN_EN = 0x0. Otherwise, if IF_EN = 0 is set during a vertical blanking period, the reception continues until the FEC synchronization code is received for all active channels.</li> </ul>	CCP2_CTRL[0] IF_EN	0x0

#### 8.2.4.4.5 ISS CCP2 Programming Select the Signaling Scheme

Table 8-62 lists the procedure to select the signaling scheme.

**Table 8-62. ISS CCP2 Select the Signaling Scheme**

Step	Bit Field	Value
Selects whether the data/strobe or data/clock signaling scheme is used. For the correct settings as a function of the image sensor class, see Section 8.2.3, ISS CSI2 PHY. This setting must also be configured in the control module.	See Section 8.2.3, ISS CSI2 PHY. For the register and bit field, see Chapter 18, Control Module (CONTROL_CAMERA_RX register).	0x0: Data/clock 0x1: Data/strobe

#### 8.2.4.4.6 ISS CCP2 Programming Select the Mode: MIPI CSI1 or CCP2

Table 8-63 lists the procedure to select MIPI CSI1 or CCP2 mode.

**Table 8-63. ISS CCP2 Select MIPI CSI1 or CCP2 Mode**

Step	Bit Field	Value
Selects whether the CCP2 module works in MIPI CSI1 or CCP2-compatible mode	CCP2_CTRL[4] MODE	0x0: Disables the CCP2-specific features (data/strobe, CRC, logical channels, RAW6, RAW7, and DPCM data formats) 0x1: CCP2 mode

#### 8.2.4.4.7 ISS CCP2 Programming Burst Settings

Table 8-64 lists the procedure to configure the burst settings.

**Table 8-64. ISS CCP2 Configure Burst Settings**

Step	Bit Field	Value
The module can be forced to perform single 64-bit requests or bursts of 2x, 4x, 8x, and 16 x 64 bits. The module must always use 16 x 64. The FIFO size is 64 x 64 bits.	<a href="#">CCP2_CTRL</a> [6:5] BURST <a href="#">CSI2_CTRL</a> [16] BURST_SIZE_EXPAND	0x0: Single request. 0x1: 2 x 64-bit bursts 0x2: 4 x 64-bit bursts 0x3: 8 x 64-bit bursts 0x4: 16 x 64-bit bursts (with burst expand)
Enable 128 bytes (recommended setting) of the DMA CSI2/CCP DMA engine to burst 128 bytes over the L3 interconnect.	<a href="#">CSI2_CTRL</a> [16] BURST_SIZE_EXPAND	0x0: Use the burst size defined in the BURST_SIZE bit field. 0x1: Allow generation of 16 x 64-bit bursts.

#### 8.2.4.4.8 ISS CCP2 Programming Debug Mode

[Table 8-65](#) lists the procedure to enable debug mode.

**Table 8-65. ISS CCP2 Enable Debug Mode**

Step	Bit Field	Value
Enable debug mode.	<a href="#">CCP2_CTRL</a> [13] DBG_EN	0x1

- During debug mode, the input comes from the [CCP2\\_DBG](#) register, not from the CCP2 physical interface. The full CCP2 receiver function can be debugged in debug mode. Full 32-bit values must always be written to the [CCP2\\_DBG](#) register.
- The following bit has no effect during debug mode:
  - [CCP2\\_CTRL](#)[0] IF\_EN
- The following examples apply to the [CCP2\\_DBG](#) register:
  - Synchronization codes: [CCP2\\_DBG](#) = 0xFF000000 (LSC) or 0xFF000001 (LEC) or 0xFF000002 (FSC) or 0xFF000003 (FEC)
  - To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, and 0x547, write [CCP2\\_DBG](#) = 0x01234567 followed by [CCP2\\_DBG](#) = 0x89abcdef and [CCP2\\_DBG](#) = 0x76543210.

**NOTE:** Each write to the [CCP2\\_DBG](#) register sends a full 32-bit word through the CCP2 receiver hardware. When 8- or 16-bit writes are performed to the register, the previous 32-bit value is merged with the newly written one. When the driver writes, for example, 0x01234567 followed by 0x0000 00FF the MPU subsystem informs that only 8 bits are written), the CCP2 receiver pipeline gets 0x01234567 followed by 0x012345FF.

#### 8.2.4.4.9 ISS CCP2 Programming Video Port

[Table 8-66](#) lists the procedure to configure the video port.

**Table 8-66. ISS CCP2 Configure Video Port**

Step	Bit Field	Value
Set the video port output frequency. It varies from ISS_FLCK down to ISS_FLCK/65,536 MHz.	<a href="#">CCP2_CTRL</a> [31:15] FRACDIV	From 1 to 65,536
Enable video port clock during vertical blanking periods or not.	<a href="#">CCP2_CTRL</a> [9] VP_CLK_FORCE_ON	0x0: The video port clock is gated during vertical blanking periods. 0x1: The video port clock is free-running during vertical blanking periods.

**Table 8-66. ISS CCP2 Configure Video Port (continued)**

Step	Bit Field	Value
Controls whether the video-port output is the only output interface enabled and applies for all channels. When <code>CCP2_CTRL[11] VP_ONLY_EN = 0x1</code> , the data are output only to the video port; the interface master port is not used. The two parts of the frame (embedded data and pixel data) are output to the video port (instead of pixel data to the video port and embedded data to the interconnect). <ul style="list-style-type: none"> <li>The video port outputs the embedded data defined by the <code>CCP2_LCx_STAT_START</code> and <code>CCP2_LCx_STAT_SIZE</code> registers without decompression.</li> <li>The video port outputs the pixel data defined by the <code>CCP2_LCx_DAT_START</code> and <code>CCP2_LCx_DAT_SIZE</code> registers.</li> </ul>	<code>CCP2_CTRL[11] VP_ONLY_EN</code>	
Control the video port pixel clock polarity: (Recommended setting: rising edge)	<code>CCP2_CTRL[12] VP_CLK_POL</code>	0x0: The CCP2 receiver writes the data on the video port on the pixel-clock falling edge. The module connected to the video port samples the data on the pixel clock rising edge. 0x1: The CCP2 receiver writes the data on the video port on the pixel-clock rising edge. The module connected to the video port samples the data on the pixel clock falling edge. <a href="#">Figure 8-32</a> shows the settings for <code>CCP2_CTRL.VP_CLK_POL</code> .

[Figure 8-32](#) shows the settings for `CCP2_CTRL.VP_CLK_POL`.

#### 8.2.4.4.10 ISS CCP2 Programming Logical Channels

The CCP2 receiver supports simultaneous logical channels. Each logical channel is controlled independently with its own set of registers. The four sets of registers are identical, but some reset values are different.

The same description applies to all four logical channels (LCx, where x = 0 to 3).

All the registers in this section can be modified at any time. However, the modifications apply only from the start of the following frame.

#### 8.2.4.4.11 ISS CCP2 Programming Controls

[Table 8-67](#) lists the procedure to enable the logical channels.

**Table 8-67. ISS CCP2 Enable Logical Channels**

Step	Bit Field	Value
Enable logical channels. It has no effect if <a href="#">CCP2_CTRL[4] MODE = 0x0</a> . By default, all logical channels except logical channel 0 are disabled. Only the pixel data of one logical channel can go to the video preprocessing hardware; the SOF and EOF lines are always sent to memory through the interconnect interface.	<a href="#">CCP2_LCx_CTRL[0] CHAN_EN</a>	0x1

#### 8.2.4.4.12 ISS CCP2 Programming Region-of-Interest

[Table 8-68](#) lists the procedure to enable the region-of-interest.

**Table 8-68. ISS CCP2 Enable Region-of-Interest**

Step	Bit Field	Value
Enables the region-of-interest feature (SOF lines, pixel data, and EOF lines): <ul style="list-style-type: none"> <li>If enabled, register settings set the position and size of each region; all data not in a region of interest are ignored.</li> <li>If disabled, all data in the frame are output. <a href="#">CCP2_LCx_CTRL[1] REGION_EN</a> is set to 0x0 for a JPEG bitstream.</li> </ul>	<a href="#">CCP2_LCx_CTRL[1] REGION_EN</a>	0x1

#### 8.2.4.4.13 ISS CCP2 Programming CRC

[Table 8-69](#) lists the procedure to enable the CRC.

**Table 8-69. ISS CCP2 Enable the CRC**

Step	Bit Field	Value
Enable the CRC. If the received checksum and the computed checksum do not match, an interrupt is triggered: the corresponding event is <a href="#">LCx_CRC_IRQ</a> . Setting <a href="#">CCP2_LCx_CTRL[2] CRC_EN = 0x1</a> has no effect if <a href="#">CCP2_CTRL[4] MODE = 0x0</a> .	<a href="#">CCP2_LCx_CTRL[2] CRC_EN</a>	0x1

#### 8.2.4.4.14 ISS CCP2 Programming Destination Format

Control the destination format:

- The CCP2 receiver reformats received data to store it in memory or to send it to the video preprocessing.
- The [CCP2\\_LCx\\_CTRL\[7:3\] FORMAT](#) bit field controls the destination-data format:
  - EXP8 = Data expansion to 8 bits, padding with zeros
  - EXP16 = Data expansion to 16 bits, padding with alpha or zeros. The [CCP2\\_CTRL\[15:8\] ALPHA](#) bit field can be used to set an alpha value. For RGB444 + EXP16:
    - `data_out [31:28] = ALPHA [3:0]`
    - `data_out [15:12] = ALPHA [3:0]`
  - EXP32 = Data expansion to 32 bits, padding with alpha. The [CCP2\\_CTRL\[15:8\] ALPHA](#) bit field can be used to set an alpha value. For RGB888 + EXP32: `data_out [31:24] = ALPHA [7:0]`
  - FSP = False synchronization protection code decoding. Applies only to JPEG8 data format.
  - VP = Output to video preprocessing is enabled.

**8.2.4.4.15 ISS CCP2 Programming Frame Acquisition**

Table 8-70 lists the procedure to acquire frames.

**Table 8-70. ISS CCP2 Frame Acquisition**

Step	Bit Field	Value
Program the number of frames that the CCP2 receiver acquires. The value of COUNT is decremented after each frame received.	<a href="#">CCP2_LCx_CTRL</a> [31:24] COUNT	0: The counter is free-running (default value). 1255: Remaining frames to be acquired
Writes to the COUNT bit field are controlled by the COUNT_UNLOCK bit.	<a href="#">CCP2_LCx_CTRL</a> [16] COUNT_UNLOCK	
Configures PING and PONG addresses	<a href="#">CCP2_LCx_DAT_PING_ADDR</a> and <a href="#">CCP2_LCx_DAT_PONG_ADDR</a>	
Indicates whether the PING address or PONG address was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in <a href="#">CCP2_CTRL</a> [0] IF_EN, the pixel data are written in the PING buffer and <a href="#">CCP2_LCx_CTRL</a> [17] PING_PONG = 0x1 (PONG). After the first FEC synchronization code is received, the pixel data are written in the PONG buffer and <a href="#">CCP2_LCx_CTRL</a> [17] PING_PONG = 0x0 (PING). <a href="#">CCP2_LCx_CTRL</a> [17] PING_PONG toggles after every FEC synchronization code.	<a href="#">CCP2_LCx_CTRL</a> [17] PING_PONG	

After the correct number of frames is received, acquisition is automatically disabled ([CCP2\\_LCx\\_CTRL](#)[0] CHAN\_EN = 0x0) and the COUNT\_IRQ interrupt is triggered. The programmer can re-enable the acquisition by resetting the [CCP2\\_LCx\\_CTRL](#)[0] CHAN\_EN bit to 0x1.

**8.2.4.4.16 ISS CCP2 Programming Synchronization Codes**

The FSC, FEC, LSC, and LEC synchronization codes have default values given by the *SMIA CCP2 Specification v1.0*. Also, each logical channel is identified by a default identifier.

The [CCP2\\_LCx\\_CODE](#) register enables overwriting of the default values: [CCP2\\_LCx\\_CODE](#)[11:8] FSC, [CCP2\\_LCx\\_CODE](#)[15:12] FEC, [CCP2\\_LCx\\_CODE](#)[3:0] LSC, and [CCP2\\_LCx\\_CODE](#)[7:4] LEC overwrite the 4 LSBs of the 32-bit synchronization codes. The default values must not be modified.

**8.2.4.4.17 ISS CCP2 Programming Status Data**

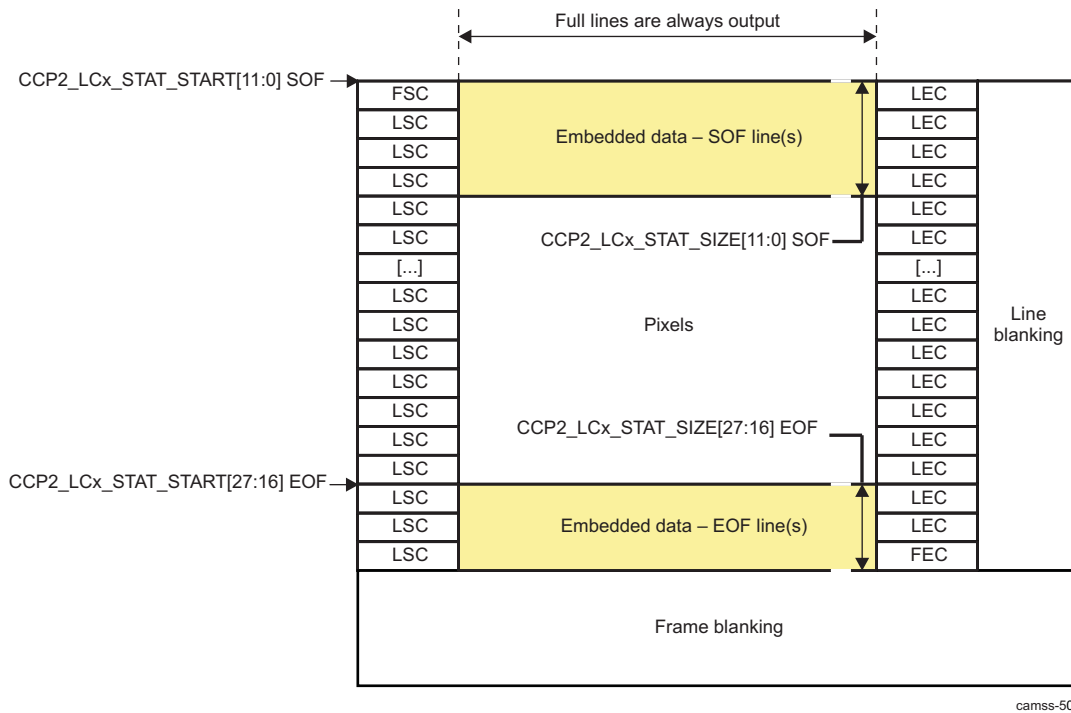

The SOF and EOF status lines can be output to memory.

The SOF and EOF status lines always cover full lines. No register settings enable the setting of width.

The [CCP2\\_LCx\\_STAT\\_START](#) register enables the setting of the vertical start position of the SOF and EOF status lines. Because the SOF status line comes first in the CCP2 frame, [CCP2\\_LCx\\_STAT\\_START](#)[11:0] SOF = 0x0.

The [CCP2\\_LCx\\_STAT\\_SIZE](#) register enables the setting of the numbers of SOF and EOF status lines. If [CCP2\\_LCx\\_STAT\\_SIZE](#)[11:0] SOF = 0x0 and [CCP2\\_LCx\\_STAT\\_SIZE](#)[27:16] EOF = 0x0, no status data are output.

Figure 8-33 shows the SOF and EOF region settings. The SOF and EOF status lines and the pixel data must not overlap, but can be consecutive.

**Figure 8-33. ISS CCP2 SOF and EOF Region Settings**

The 32-bit destination addresses of the SOF status lines are set by the [CCP2\\_LCx\\_SOF\\_ADDR](#) register.

**NOTE:** The destination addresses of the SOF status lines must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The SOF lines are packed together at the destination address.

The 32-bit destination addresses of the EOF status lines are set by the [CCP2\\_LCx\\_EOF\\_ADDR](#) register.

**NOTE:** The destination addresses of the EOF status lines must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The EOF lines are packed together at the destination address.

**NOTE:** The CCP2 receiver does not modify the data in the SOF and EOF status lines. The data are received and written with no modifications.

#### 8.2.4.4.18 ISS CCP2 Programming Pixel Data Region

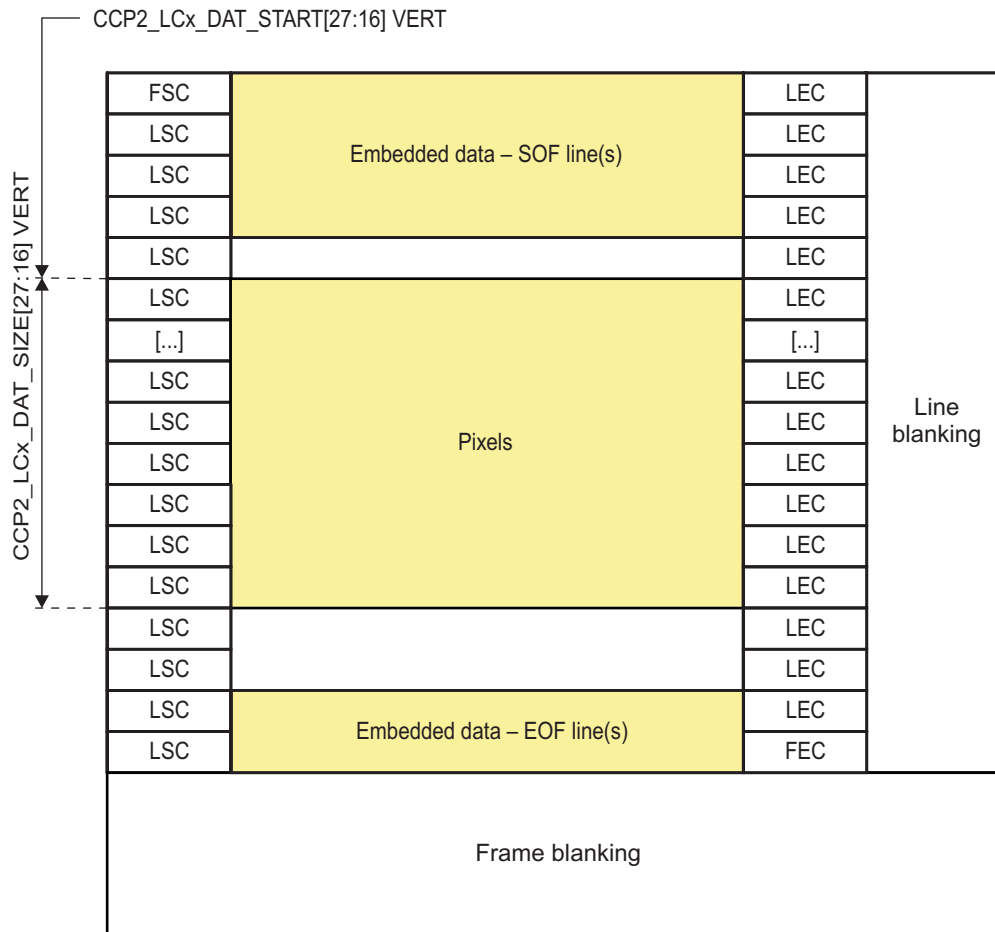

Pixel data can be output to memory or to the video-preprocessing hardware.

The pixel data region covers full lines. The [CCP2\\_LCx\\_DAT\\_SIZE](#) register sets the horizontal size of the pixel region. The vertical size is expressed in lines.

The [CCP2\\_LCx\\_DAT\\_START](#) register enables the setting of the vertical start position of the pixel data. The vertical start position is expressed in lines.

[Figure 8-34](#) shows the pixel region settings.

**Figure 8-34. ISS CCP2 Pixel Data Region Settings**

camss-502

The 32-bit destination addresses of the pixel data are set by the [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#) and [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#) registers.

**NOTE:** The destination address must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The pixel data lines are packed together at the destination address.

It is possible to perform double-buffering (ping-ponging) at the destination by setting different addresses in the [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#) and [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#) registers. It is possible to disable double-buffering by setting up the same address in both registers. The [CCP2\\_LCx\\_CTRL\[17\]](#) PING\_PONG bit must be used by software to determine which address contains the latest frame.

A destination pitch controls the address jump between the address of the first pixel of the previous line and the address of the first pixel of the current line. The destination pitch is set in bytes with the [CCP2\\_LCx\\_DAT\\_OFST](#) register. It applies for [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#) and [CCP2\\_LCx\\_DAT\\_PONG\\_ADDR](#).

**NOTE:** The destination pitch must be a multiple of 32 bytes; the 5 LSBs of the address are ignored.

The destination data format is set with the [CCP2\\_LCx\\_CTRL\[7:2\]](#) FORMAT bit field.

For the PING frame:

- @Line0 = [CCP2\\_LCx\\_DAT\\_PING\\_ADDR](#)
- @Line1 = @Line0 + [CCP2\\_LCx\\_DAT\\_OFST](#)

- @Line2 = @Line1 + CCP2\_LCx\_DAT\_OFST

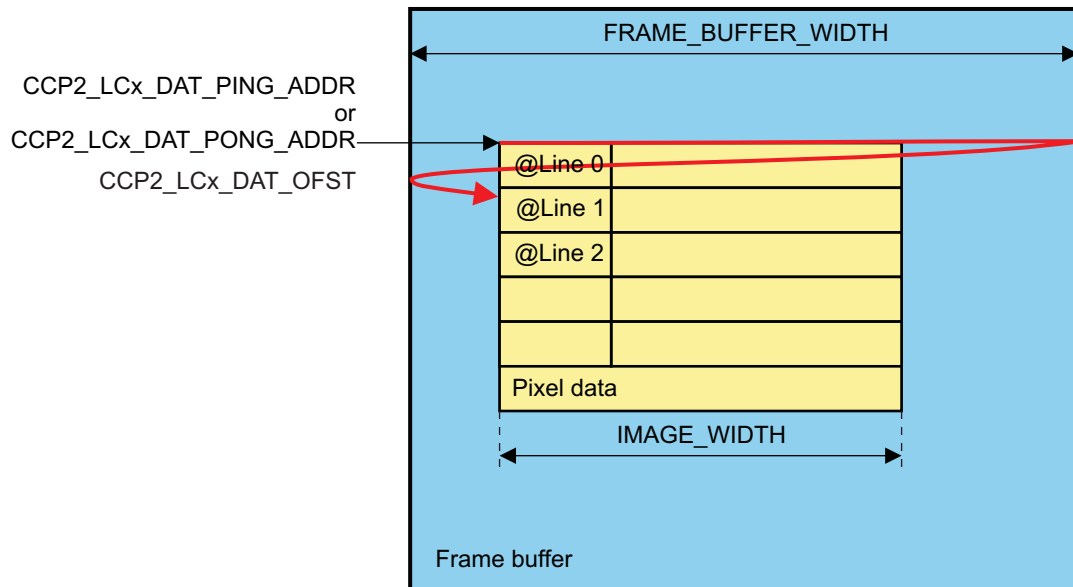

For the PONG frame:

- @Line0 = CCP2\_LCx\_DAT\_PONG\_ADDR
- @Line1 = @Line0 + CCP2\_LCx\_DAT\_OFST
- @Line2 = @Line1 + CCP2\_LCx\_DAT\_OFST

When CCP2\_LCx\_DAT\_OFST = 0x0, the lines are written contiguously in memory. The destination pitch enables 2D transfers; it is required to write the pixel data directly in the frame buffer, for instance.

In such cases, CCP2\_LCx\_DAT\_OFST = FRAME\_BUFFER\_WIDTH. Figure 8-35 shows the pixel data destination settings.

**Figure 8-35. ISS CCP2 Pixel Data Destination Settings**

camss-503

#### 8.2.4.4.19 ISS CCP2 Programming Memory Read Channel

##### 8.2.4.4.19.1 ISS CCP2 Write Data From Sensor to Memory

Data can be captured from the sensor using any logical channel. To keep the native data format, the channel format must be set to YUV4:2:2 little-endian format.

##### 8.2.4.4.19.2 ISS CCP2 Read Data From Memory

Table 8-71 lists the procedure to configure read data from memory.

**Table 8-71. ISS CCP2 Configure Read Data From Memory**

Step	Bit Field	Value
Disable all logical channels.	CCP2_CTRL[0] IF_EN	0x0
Wait until disabling of the physical interface is effective before enabling the memory read channel.	CCP2_CTRL[3] FRAME	0x1
Configure the burst size. The recommended value for best performance is 0x4 (16 × 64-bit burst).	CCP2_LCM_CTRL[7:5] BURST_SIZE	–

**Table 8-71. ISS CCP2 Configure Read Data From Memory (continued)**

Step	Bit Field	Value
Configure the source data format, location, and framing. In addition to the <a href="#">CCP2_LCM_HSIZE[11:0]</a> SKIP and <a href="#">CCP2_LCM_HSIZE[27:16]</a> COUNT bit fields, firmware must specify the amount of data to be fetched from memory. This value is set in 64-bit word steps and must be a multiple of 32 bytes (four words of 64 bits). The value is computed with the following formula: $\text{HWORDS} = 4 \times \text{ceil}((\text{SKIP} + \text{COUNT}) \times \text{bits\_per\_pixel}) / (8 \times 32) \quad (3)$ The <a href="#">CCP2_LCM_SRC_ADDR</a> and <a href="#">CCP2_LCM_SRC_OFST</a> registers must be aligned on 32-byte boundaries for correct operation. For best performance, both registers must be aligned on 256-byte boundaries. See the example following this table.	<a href="#">CCP2_LCM_CTRL</a> , <a href="#">CCP2_LCM_HSIZE</a> , <a href="#">CCP2_LCM_VSIZE</a> , <a href="#">CCP2_LCM_PREFETCH</a> , <a href="#">CCP2_LCM_SRC_ADDR</a> , <a href="#">CCP2_LCM_SRC_OFST</a>	
Select destination.	<a href="#">CCP2_LCM_CTRL[2]</a> DST_PORT	0x0: Video port 0x1: Memory
If destination = video port, configure clock frequency and its gating during frame blanking periods.	<a href="#">CCP2_CTRL[31:15]</a> FRACDIV, <a href="#">CCP2_CTRL[9]</a> VP_CLK_FORCE_ON	
If needed, configure READ_THROTTLE to reduce the bandwidth in memory-to-memory operation to prevent system overload. It has no effect when data are sent to the video port (controlled by video port clock in this case).	<a href="#">CCP2_LCM_CTRL[4:3]</a> READ_THROTTLE	
If the memory write port is used, the destination format and address must be configured.	<a href="#">CCP2_LCM_DST_ADDR</a> , <a href="#">CCP2_LCM_DST_OFST</a>	
Enable memory read channel. After processing a full frame, this bit is automatically cleared by hardware and an EOF event is triggered.	<a href="#">CCP2_LCM_CTRL[0]</a> CHAN_EN	0x1

**Example:**

- [CCP2\\_LCM\\_CTRL\[7:5\]](#) BURST\_SIZE is set to 16 × 64 bits
- [CCP2\\_LCM\\_HSIZE\[11:0\]](#) SKIP = 0
- [CCP2\\_LCM\\_HSIZE\[27:16\]](#) COUNT = 1000
- [CCP2\\_LCM\\_CTRL\[23\]](#) SRC\_PACK = YES
- [CCP2\\_LCM\\_CTRL\[18:16\]](#) SRC\_FORMAT = RAW6
- [CCP2\\_LCM\\_PREFETCH\[15:3\]](#) HWORDS = 96 (>=94)  
 Setting the size to 94 produces the following burst sequence: 16, 16, 16, 16, 16, 8, and 4 (7 interconnect requests). However, when it is set to 96, the burst sequence is 6 × 16 (6 interconnect requests).

**8.2.4.5 ISS CCP2 Register Manual**
**8.2.4.5.1 ISS CCP2 Instance Summary**

[Table 8-72](#) summarizes the CCP2 instance.

<b>Address Offset</b>	0x0000 0040	<b>Instance</b>	ISS_CCP2
<b>Physical Address</b>	<a href="#">0x5200 1C40</a>		
<b>Description</b>	GLOBAL CONTROL REGISTER This register controls the CCP2 receiver. This register shall not be modified dynamically (except IF_EN bit field).		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
FRACDIV																	POSTED	DBG_EN	VP_CLK_POL	VP_ONLY_EN	RESERVED	VP_CLK_FORCE_ON	RESERVED	BURST	MODE	FRAME	RESERVED	RESERVED	IF_EN																

Bits	Field Name	Description	Type	Reset
31:15	FRACDIV	Fractional clock divider control for the video port. The mean video port clock is VPBASECLOCK * FRACDIV/65536. Valid range: 1-65536	RW	0x10000
14	POSTED	Selects between posted and non posted writes. 0x0: Non posted 0x1: Posted	RW	0
13	DBG_EN	Enables the debug mode. 0x0: Disable 0x1: Enable	RW	0
12	VP_CLK_POL	VP clock polarity 0x0: The CCP2 receiver writes the data on the VP on the L3 falling edge before the next falling PCLK edge. 0x1: The CCP2 receiver writes the data on the VP on the L3 rising edge before the next rising PCLK edge.	RW	0
11	VP_ONLY_EN	VP only enable. 0x0: The VP is enabled and the OCP master port are enabled. 0x1: The VP is enabled and the OCP master port is disabled. The embedded data and pixel data are output on the VP.	RW	0
10	RESERVED	Read returns reset value	RW	0

Bits	Field Name	Description	Type	Reset
9	VP_CLK_FORCE_ON	Controls VP_PCLK gating during frame blanking periods. 0x0: The VP_PCLK is gated during vertical blanking periods. 0x1: The VP_PCLK is free-running during vertical blanking periods.	RW	0
8	RESERVED		R	0
7:5	BURST	Forces the write burst size used by the module. The write burst size shall never exceed the output FIFO size. The output FIFO size can be read with the <a href="#">CCP2_GNQ.FIFODEPTH</a> bit field. 0x0: 1x 64-bit burst = single request. 0x1: 2x 64-bit bursts. 0x3: 8x 64-bit bursts. 0x4: 16x 64-bit bursts. 0x2: 4x 64-bit bursts.	RW	0x0
4	MODE	Selects the receiver operating mode. This bit is only writable when the CCP2MODE input is 1. 0x0: MIPI CSI1 compatible mode. When this bit is set all CCP2 settings are ignored. If the settings are not set correctly to MIPI CSI1 values, the behavior of the receiver is unpredictable. 0x1: CCP2 compatible mode	RW	0
3	FRAME	Set the modality in which IF_EN works. 0x0: When software writes IF_EN = 0 the interface is disabled immediately. 0x1: When software writes IF_EN = 0 the interface is disabled after the next FEC sync code.	RW	0
2	RESERVED	Read returns reset value	RW	0
1	RESERVED	Read returns reset value	RW	0
0	IF_EN	Enables the physical interface to the module. 0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled on the next FEC sync code. If FRAME=1, it is advised to disable the logical channels first (CCP2_LCX_CTRL.CHAN_EN=0) before writing IF_EN=0. 0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, that is, the CCP2_LCX_CTRL.PING_PONG bits are reset to 1 as well.	RW	0

<b>Address Offset</b>	0x0000 01D0	<b>Instance</b>	ISS_CCP2
<b>Physical Address</b>	0x5200 1DD0		
<b>Description</b>	Control register for the memory channel. It defines the data format of the source frame stored in memory and how this frame is processed.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DST_PACK	DST_DPCM_PRED	DST_COMPR	RESERVED	DST_FORMAT	SRC_PACK	SRC_DPCM_PRED	SRC_DECOMPR	SRC_FORMAT				RESERVED								BURST_SIZE	READ_THROTTLE	DST_PORT	RESERVED	CHAN_EN							

Bits	Field Name	Description	Type	Reset
31	DST_PACK	Data is packed before it is send to memory. Applies to RAW6, RAW7, RAW10, and RAW12 only. 0x0: Disabled 0x1: Enabled	RW	0

Bits	Field Name	Description	Type	Reset
30	DST_DPCM_PRED	Selects the DPCM predictor to be used for the RAW6+DPCM10 and RAW7+DPCM10 data formats. The RAW8+DPCM10 data format always use the simple predictor. 0x0: The advanced predictor is used 0x1: The simple predictor is used.	RW	0
29:28	DST_COMPR	Enables data compression of data sent to memory 0x0: No compression 0x1: A-Law compression RAW10 -> RAW8 A-Law when DST_FORMAT=RAW8 other destination formats are invalid. 0x2: DPCM compression RAW10 -> RAW6 DPCM when DST_FORMAT=RAW6 RAW10 -> RAW7 DPCM when DST_FORMAT=RAW7 RAW10 -> RAW8 DPCM when DST_FORMAT=RAW8 other destination formats are invalid.	RW	0x0
27	RESERVED		R	0
26:24	DST_FORMAT	Output format selection. Not every combination between input and output formats are possible. 0x6: RAW16 0x1: RAW7 0x0: RAW6 0x2: RAW8 0x4: RAW12 0x5: RAW14 0x3: RAW10	RW	0x0
23	SRC_PACK	Data stored in memory is packed and must be unpacked. 0x0: Disabled 0x1: Enabled	RW	0
22	SRC_DPCM_PRED	Selects the DPCM predictor to be used for the RAW6+DPCM10, RAW7+DPCM10 and RAW8+DPCM12 data formats. The RAW8+DPCM10 and RAW6 + DPCM12 data format always use the simple predictor. 0x0: The advanced predictor is used 0x1: The simple predictor is used.	RW	0
21:20	SRC_DECOMPR	Enable decompression of incoming data 0x0: No decompression 0x1: A-Law decompression RAW8 A-Law -> RAW10 when SRC_FORMAT=RAW8 other source formats are invalid. 0x3: DPCM decompression RAW6 DPCM -> RAW12 when SRC_FORMAT=RAW6 RAW8 DPCM -> RAW12 when SRC_FORMAT=RAW8 other source formats are invalid. 0x2: DPCM decompression RAW6 DPCM -> RAW10 when SRC_FORMAT=RAW6 RAW7 DPCM -> RAW10 when SRC_FORMAT=RAW7 RAW8 DPCM -> RAW10 when SRC_FORMAT=RAW8 other source formats are invalid.	RW	0x0

Bits	Field Name	Description	Type	Reset
19:16	SRC_FORMAT	Data format of the data stored in memory. As there is no header embedded in the data sent to memory the user is responsible of choosing the adequate format.  0x6: RAW16 0x1: RAW7 0xA: Reserved 0x7: Reserved 0xD: Reserved 0x0: RAW6 0x2: RAW8 0x8: Reserved 0x9: Reserved 0xB: Reserved 0x4: RAW12 0x5: RAW14 0xF: Reserved 0xC: Reserved 0x3: RAW10 0xE: Reserved	RW	0x0
15:8	RESERVED		R	0x00
7:5	BURST_SIZE	Defines the burst size of the master read port  0x0: 1x 64-bit burst = single request. 0x1: 2x 64-bit bursts. 0x3: 8x 64-bit bursts. 0x4: 16x 64-bit bursts. 0x2: 4x 64-bit bursts.	RW	0x0
4:3	READ_THROTTLE	Limit maximum data read speed for memory to memory operation  0x0: Full speed. Throughput is limited by internal processing capabilities. 0x1: 1/2 speed 0x3: 1/8 speed 0x2: 1/4 speed	RW	0x0
2	DST_PORT	Select the destination port  0x0: Data is send to video port, it is always send without compression or packing. The DST_COMPR, DST_DPCM_PRED, DST_PACK, CCP2_LCM_DST_WRITE, and CCP2_LCM_DST_OFST registers have no effect. 0x1: Data is send to memory.	RW	0
1	RESERVED		R	0
0	CHAN_EN	Enables the read from memory channel. Before enabling the memory read channel software shall: - disable the physical interface using the IF_EN bit - wait until disabling of the physical interface is effective (depends on the FRAME bit) Read from memory starts as soon as this bit is set, therefore all CCP2_LCM_x registers must be configured correctly before. This bit is cleared by hardware at the end of the frame.  0x0: Disabled 0x1: Enabled	RW	0

## 8.2.5 ISS CSI2

### 8.2.5.1 ISS CSI2 Environment

#### 8.2.5.1.1 ISS CSI2 Protocol and Data Format

The CSI2 supports MIPI CSI2 multiple data type formats. This section describes MIPI CSI2 protocol and data formats. The CSI2 is compatible with the *MIPI CSI2 Specification v1.0-01-00 r0.03*. [Table 8-140](#) lists the MIPI CSI2 supported by CSI2 formats in addition to JPEG8. Shading in the primary and secondary MIPI CSI2-defined formats indicates special format extensions of the CSI2 receiver.

[Table 8-140](#) summarizes the pixel formats supported by the CSI2 receiver interface.

**Table 8-140. ISS CSI2 Pixel Format Modes**

CSI2_CTX_CT RL2_i[9:0] Format	CSI2 Data Format	Bits per Pixel (BPP)	Data Size Increases in Memory	2D Mode Availability <sup>(1)</sup>	Comments

0x12	JPEG8	8	0%		

<sup>(1)</sup> If 2D mode is available, there are no supplementary constraints on data width. 2D mode does not apply when sending to the video port (VP).

For more information about how the data formats are transmitted and how the data are stored in memory, see [Section 8.2.5.1.1.4, CSI2 Operating Modes](#).

---

**NOTE:** The VP formats are not included in [Table 8-140](#), because they are not sent to memory; instead they are sent to the ISP for further processing.

---

---

**NOTE:** Data written by CSI2 can be read back by the CCP2 read channel. CCP2 can get data from a sensor or memory. For more information about supported memory operations, see [Table 8-56](#).

---

### 8.2.5.1.1.1 ISS CSI2 Physical Layer

The CSI2-A/CSI2-B receivers are tightly connected to a PHY layer (for more information about the PHY, see [Section 8.2.3, ISS CSI2 PHY](#)). [Table 8-141](#) lists the CSI2-A receiver I/O, and [Table 8-142](#) lists the CSI2-B I/O. The CSI2\_RECEIVER provides access to the complex I/O configuration from the [CSI2\\_COMPLEXIO\\_CFG](#) register.

**Table 8-141. ISS CSI2-A I/O Description**

Signal Name		I/O <sup>(1)</sup>	Description
csi2a_dx0	lane 0 (position 1)	I	Serial data/clock input
csi2a_dy0			
csi2a_dx1	lane 1 (position 2)	I	Serial data/clock input
csi2a_dy1			
csi2a_dx2	lane 2 (position 3)	I	Serial data/clock input
csi2a_dy2			
csi2a_dx3	lane 3 (position 4)	I	Serial data/clock input
csi2a_dy3			
csi2a_dx4	lane 4 (position 5)	I	Serial data input only
csi2a_dy4			

<sup>(1)</sup> I = Input

**Table 8-142. ISS CSI2-B I/O Description**

Signal Name		I/O <sup>(1)</sup>	Description
csi2b_dx0	line 0 (position 1)	I	Serial data/clock input
csi2b_dy0			
csi2b_dx1	line 1 (position 2)	I	Serial data/clock input
csi2b_dy1			
csi2b_dx2	line 2 (position 3)	I	Serial data/clock input
csi2b_dy2			

<sup>(1)</sup> I = Input

---

**NOTE:** The serial lane can be used as clock lane or data lane (excluding lane 4 on the CSI2-A I/O). The MIPI CSI2 protocol requires one clock lane (others are data lane or unused lane).

---

Lanes support the two operating modes:

- HS mode: High-speed transmit mode
- Off mode: Lane is off.

### 8.2.5.1.1.2 ISS CSI2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The lane merger can merge up to four lanes (CSI2-A) into a single byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2-A, CSI2-B receiver core depends on the lane configuration. The merger is not used for a single lane.

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

Figure 8-36 to Figure 8-39 show the byte position into each serial link for one to four data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

**Figure 8-36. ISS CSI2 One Data-Lane Configuration**

camss-240

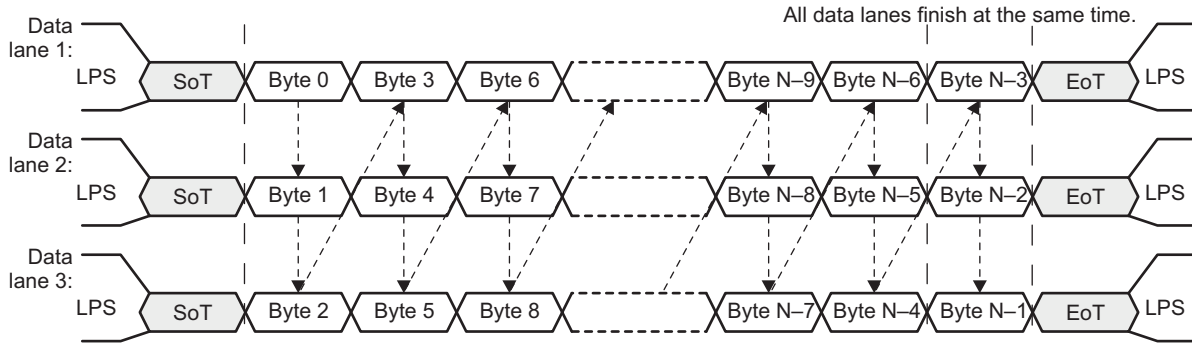

**Figure 8-37. ISS CSI2 Two Data-Lane Merger Configuration**

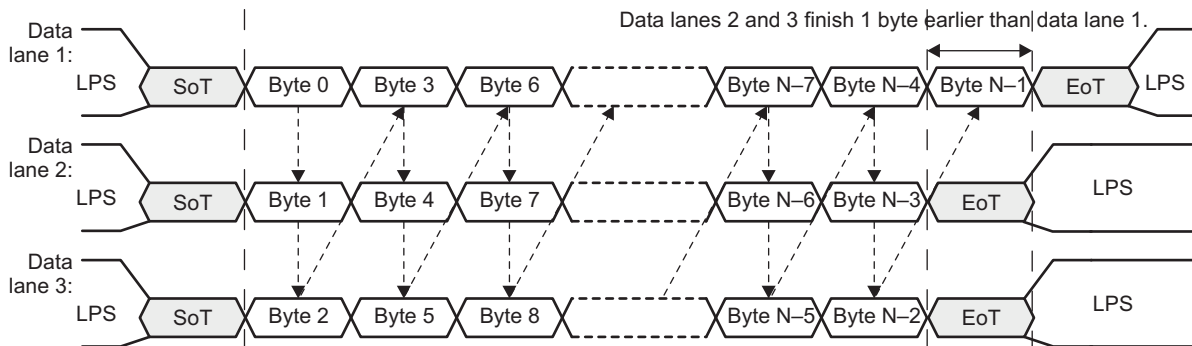

camss-239

**Figure 8-38. ISS CSI2 Three Data-Lane Merger Configuration**

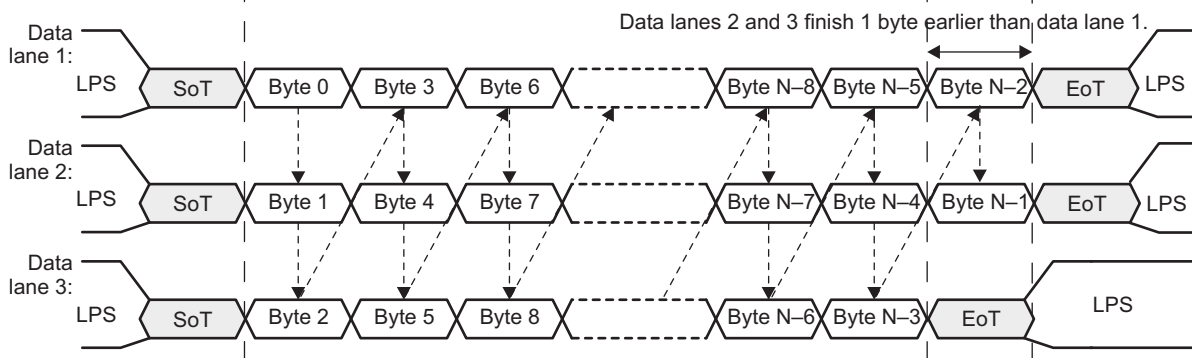

Number of bytes, N, transmitted is an integer multiple of the number of data lanes:

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes (Example 1):

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes (Example 2):

camss-257

**Figure 8-39. ISS CSI2 Four Data-Lane Merger Configuration**

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes:

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes:

camss-258

### 8.2.5.1.1.3 ISS CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

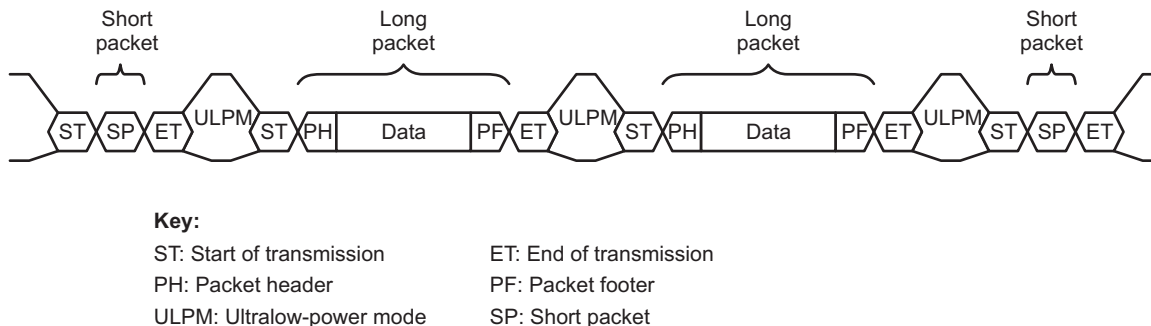

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 8-40 shows the CSI2 protocol layer with short and long packets.

**Figure 8-40. ISS CSI2 Protocol Layer With Short and Long Packets**

camss-241

Two packets are always separated from each other with a sequence of ET, ULPM, and ST.

**8.2.5.1.1.3.1 ISS CSI2 Short Packet**

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. Figure 8-41 shows the structure of a short packet.

**Figure 8-41. ISS CSI2 Short Packet Structure**

camss-242

For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0 and is inoperative.
- The frame number increments by 1 for every FS packet within the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For LSC and LEC synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the use case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0 and is inoperative.
- The line number increments by 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended use is for progressive scan (noninterlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero

arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be different between successive frames. The intended use is for interlaced video data streams.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (up to eight contexts support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

### 8.2.5.1.1.3.2 ISS CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements:

- A 32-bit packet header (PH)
- An application-specific data payload with a variable number of 8-bit data words
- A 16-bit packet footer (PF)

The packet header is composed of three elements:

- An 8-bit data identifier
- A 16-bit word count field
- An 8-bit ECC

The packet footer has one element, a 16-bit checksum.

Figure 8-42 and Table 8-143 show the structure of a long packet.

**Figure 8-42. ISS CSI2 Long Packet Structure**

camss-243

**Table 8-143. ISS CSI2 Long Packet Structure Description**

Packet Part	Field Name	Size (Bits)	Description
Header	Data ID	8	Contains the virtual channel identifier and the data-type information
	Word count	16	Number of data words in the packet data. A word is 8 bits.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC-8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit CRC for packet data

There are no restrictions on the size of the packet data, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

### 8.2.5.1.1.3.3 ISS CSI2 Data Identifier

The data identifier byte contains the virtual channel (VC) value and the data-type (DT) value, as shown in Figure 8-43. The VC value is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 8-43 shows the data identifier structure.

**Figure 8-43. ISS CSI2 Data Identifier Structure**

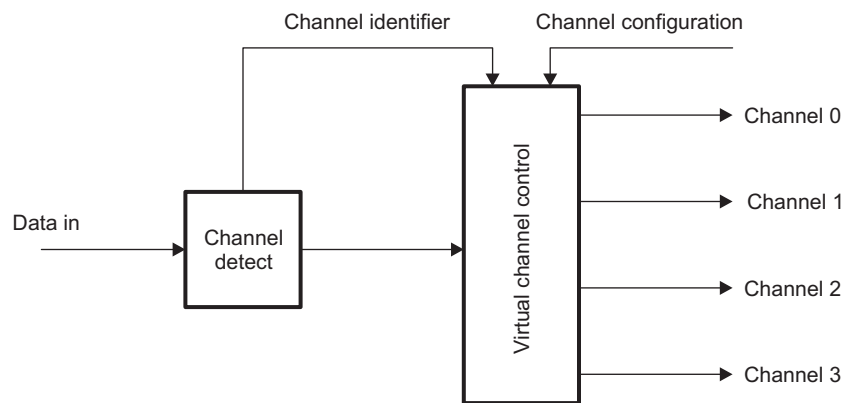

camss-244

### Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. Line start and line end synchronization codes are optional for the transmitter. A set of registers is associated with each context defined by the virtual channel ID and the data type. Figure 8-44 shows a virtual channel.

**Figure 8-44. ISS CSI2 Virtual Channel**

camss-245

### Pixel Formats

#### 8.2.5.1.1.3.4 ISS CSI2 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bitstream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the last line and the end of the current frame

Table 8-144 summarizes the synchronization code values.

**Table 8-144. ISS CSI2 Synchronization Codes**

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

#### 8.2.5.1.1.3.5 ISS CSI2 Generic Short Packet Codes

When the synchronization code value is from 0x8 to 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

#### 8.2.5.1.1.3.6 ISS CSI2 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit nonimage data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

#### 8.2.5.1.1.3.7 ISS CSI2 Frame Structure

Each frame consists of short packets to indicate SOF and EOF. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as SOF and EOF information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame contains embedded data and image-sensor data. [Figure 8-45](#) shows where the embedded data and image-sensor data are in the frame. The frame is scanned in raster order starting from the top-left corner, as shown in [Figure 8-45](#) and [Figure 8-46](#). The following definitions for a frame apply:

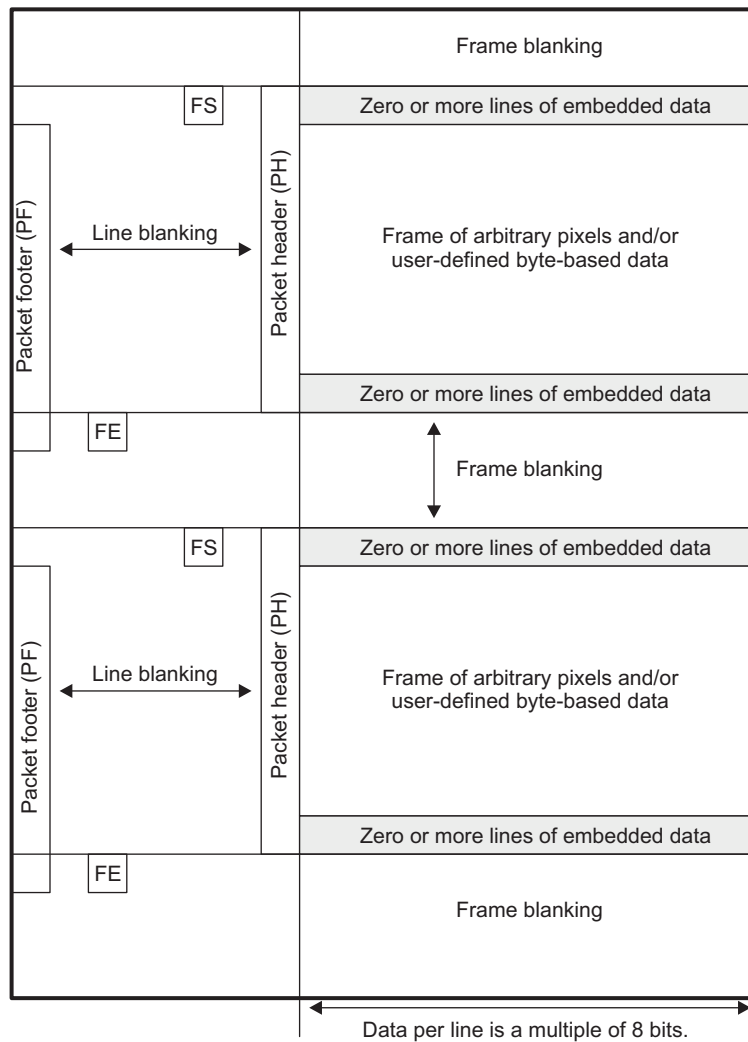

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image embedded data is carried using separate data types and virtual channels (see [Section 8.2.4.1.1, ISS CCP2 Protocol and Data Formats](#), and [Section 8.2.5.3.3.4, ISS CSI2 Virtual Channel and Context](#)).
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for use by software.

Because the data types are different, the data is carried using separate data types called virtual channels. Those must be mapped to the adequate context. The CSI2 receiver uses a different context for embedded data and image-sensor data. See [Section 8.2.5.3.3.4, ISS CSI2 Virtual Channel and Context](#).

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Figure 8-45. ISS CSI2 General Frame Structure (Informative)

**Key:**

 FS: Frame start  
 LS: Line start

PF: Packet footer  
 FE: Frame end  
 LE: Line end

camss-247

The period between the LEC and the new LSC is the line blanking period. The time between the FEC and the new FSC is the frame blanking period. The receiver works with the line blanking period set to 0. The image data is stored in memory by selecting one of the various operating modes. [Section 8.2.5.1.1.4, ISS CSI2 Operating Modes](#), explains storing image data frames into memory.

**8.2.5.1.1.4 ISS CSI2 Operating Modes****8.2.5.1.1.4.1 ISS CSI2 YUV Operating Modes****8.2.5.1.1.4.1.1 ISS CSI2 YUV4:2:0 8-Bit**

YUV4:2:0 8-bit data can be stored to memory in little-endian and big-endian format. To set the endianness for YUV4:2:0 use the [CSI2\\_CTRL\[4\] ENDIANNES](#)S bit. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 32 bits and the number of lines must be even. Figure 8-47 shows the storage format for YUV4:2:0 8-bit data. It is shown as little endian. If the data format is big endian, the figure changes accordingly. Set the `CSI2_CTX_CTRL2_j[9:0]` FORMAT bit field to 0x18 to select YUV4:2:0 8-bit mode. Even and odd lines do not have the same length. Offset must be set accordingly with the `CSI2_CTX_DAT_OFST_j[16:5]` OFST bit field; for example, if the offset is 0, the data is written in a contiguous way (bit-to-bit of odd and even lines). If the data has an offset, set the destination offset between the first pixel of the previous line and the first pixel of the current line being written to memory.

Figure 8-47. ISS CSI2 YUV4:2:0 8-Bit

YUV4:2:0 8-bit

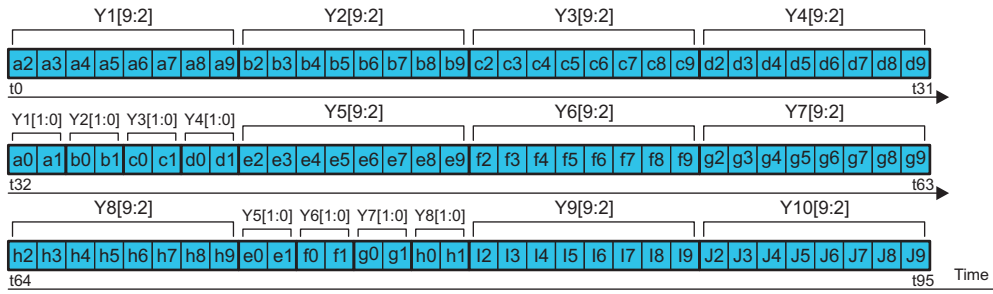

**8.2.5.1.1.4.1.2 ISS CSI2 YUV4:2:0 10-Bit**

YUV4:2:0 10-bit data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines. [Figure 8-48](#) shows the storage format for YUV4:2:0 10-bit data. Set the [CSI2\\_CTX\\_CTRL2\\_i\[9:0\]](#) FORMAT bit field to 0x19 to select YUV4:2:0 10-bit mode. Even and odd lines do not have the same length. Offset must be set accordingly with the [CSI2\\_CTX\\_DAT\\_OFST\\_i\[16:5\]](#) OFST bit field.

### 8.2.5.1.1.4.1.3 CSI2 YUV4:2:0 8-Bit Legacy

YUV4:2:0 8-bit legacy data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 4 bytes. Figure 8-49 shows the storage format for YUV4:2:0 8-bit legacy data. Set the `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field to 0x1A to select YUV4:2:0 8-bit legacy mode.

**Figure 8-49. ISS CSI2 YUV4:2:0 8-Bit Legacy**

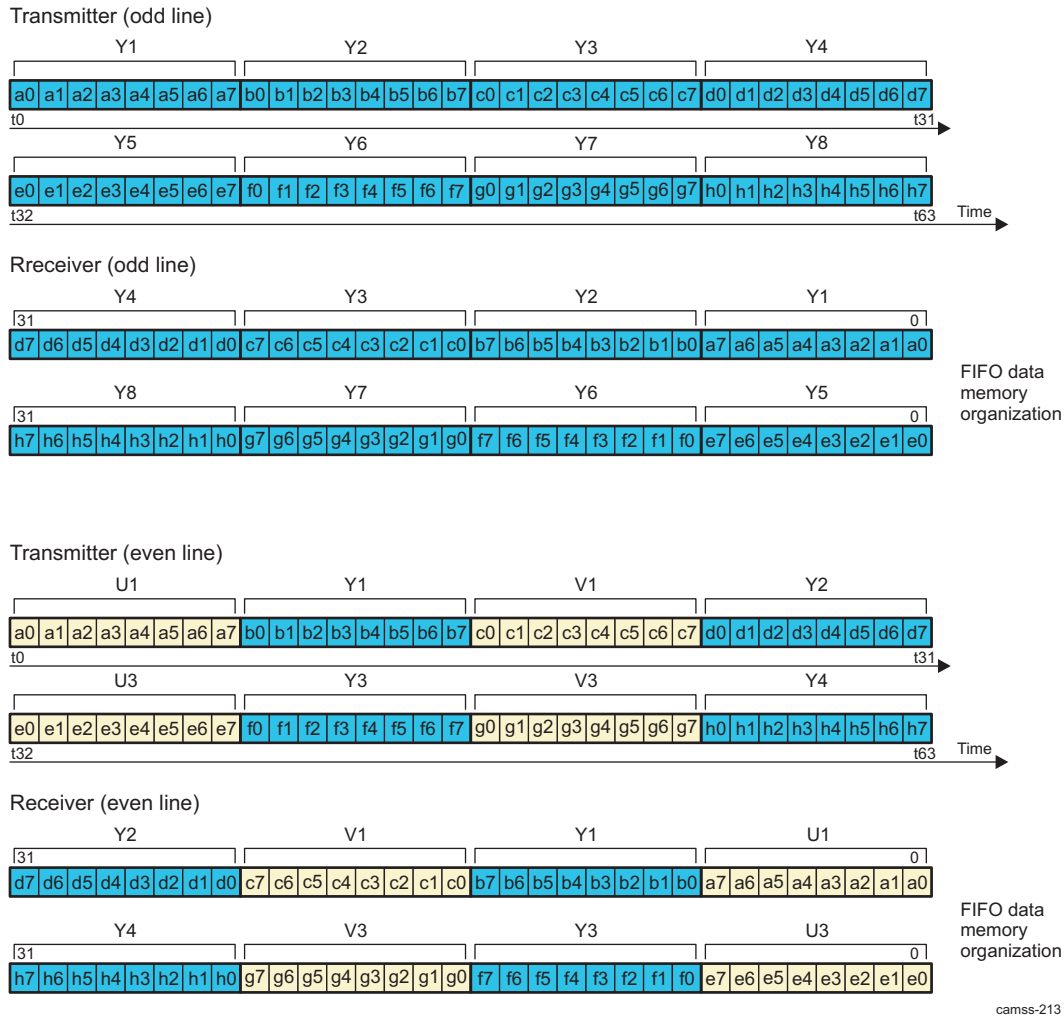

### 8.2.5.1.1.4.1.4 ISS CSI2 YUV4:2:0 8-Bit + CSPS

YUV4:2:0 8-bit CSPS data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 32 bits and the number of lines must be even. Figure 8-50 shows the storage format for YUV4:2:0 8-bit + CSPS data. Set the `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field to 0x1C to select YUV4:2:0 8-bit + CSPS mode.

Figure 8-50. ISS CSI2 YUV4:2:0 8-Bit + CSPS

YUV4:2:0 8-bit + CSPS

camss-213

### 8.2.5.1.1.4.1.5 Camera ISP CSI2 Byte Swap

The CSI2 receiver incorporates a byte-swapping function. Software can optionally enable byte-swapping of the payload data by setting the CSI2\_CTLx\_CTRL1[31] BYTESWAP bit. This feature must be used only when the amount of payload data per packet is a multiple of 16 bits. The byte-swapping is performed before pixel reconstruction.

**Figure 8-51. Camera ISP CSI2 Byte Swap**

ISS CSI2 byte-swap

For example, CSI2\_CTX\_CTRL2[9:0] FORMAT = RAW8

Transmitter

Receiver when CSI2\_CTX\_CTRL1[31] BYTESWAP = 0x0

isp-001

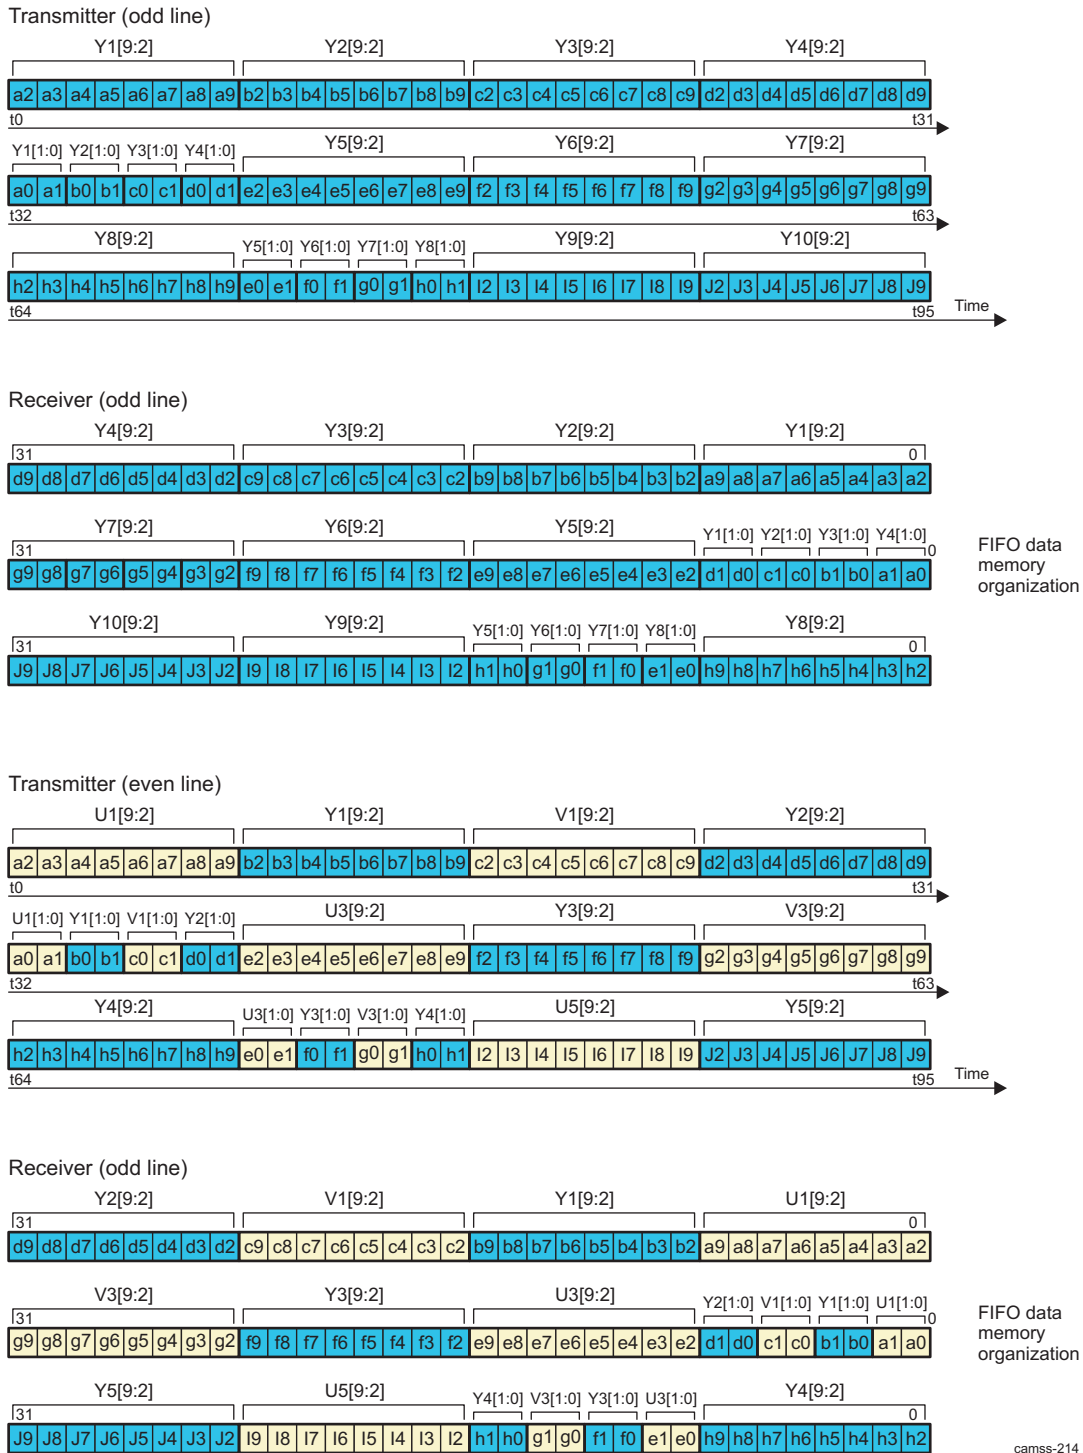

**8.2.5.1.1.4.1.6 ISS CSI2 YUV4:2:0 10-Bit + CSPS**

YUV4:2:0 10-bit CSPS data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3 32 bits and the number of lines must be even. [Figure 8-52](#) shows the storage format for YUV4:2:0 10-bit + CSPS data. Set the [CSI2\\_CTX\\_CTRL2\\_i\[9:0\] FORMAT](#) bit field to 0x1D to select YUV4:2:0 10-bit + CSPS mode.

Figure 8-52. ISS CSI2 YUV4:2:0 10-Bit + CSPPS

YUV4:2:0 10-bit + CSPPS

camss-214

### 8.2.5.1.1.4.1.7 ISS CSI2 YUV4:2:2 8-Bit

YUV4:2:2 data can be stored to memory in little-endian and big-endian format. To set the endianness for YUV4:2:2 use the `CSI2_CTRL[4]` ENDIANNESS bit. The line length sent through the CSI2 physical protocol is a multiple of 32 bits. [Figure 8-53](#) shows the storage format for YUV4:2:2 8-bit data. Set the `CSI2_CTX_CTRL2_j[9:0]` FORMAT bit field to 0x1E to select YUV4:2:2 8-bit mode.

**Figure 8-53. ISS CSI2 YUV4:2:2 8-Bit**

YUV4:2:2 8-bit

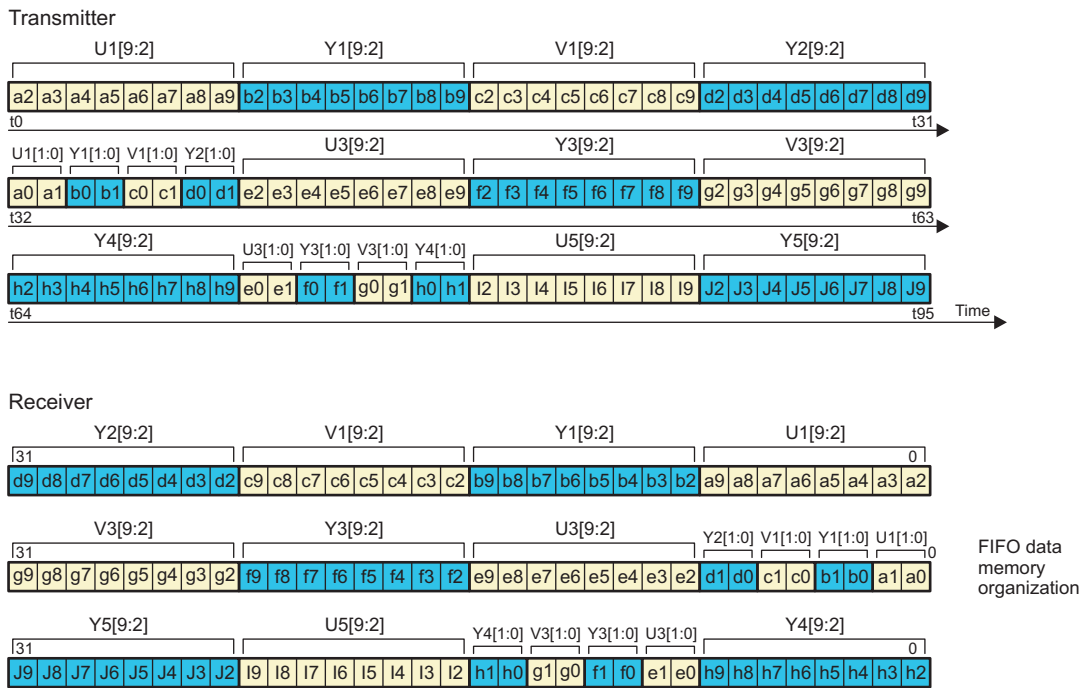

### 8.2.5.1.1.4.1.8 CSI2 YUV4:2:2 10-Bit

YUV4:2:2 data can be stored to memory in little-endian and big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits. [Figure 8-54](#) shows the storage format for YUV4:2:2 10-bit data. Set the `CSI2_CTX_CTRL2_j[9:0]` FORMAT bit field to 0x1F to select YUV4:2:2 10-bit mode.

Figure 8-54. ISS CSI2 YUV4:2:2 10-Bit

YUV4:2:2 10-bit

camss-216

### 8.2.5.1.1.4.2 ISS CSI2 RGB Operating Modes

#### 8.2.5.1.1.4.2.1 ISS CSI2 RGB565

RGB565 data is output to memory without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 16 bits. Figure 8-55 shows the storage format for RGB565 data. Set the CSI2\_CTX\_CTRL2\_i[9:0] FORMAT bit field to 0x22 to select RGB565 mode.

Figure 8-55. ISS CSI2 RGB565

RGB565

camss-217

### 8.2.5.1.1.4.2.2 ISS CSI2 RGB888

RGB888 data can be output to memory in two formats: with or without data expansion. If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications (the `CSI2_CTX_CTRL3_i[29:16]` ALPHA bit field). Figure 8-56 shows the storage format for RGB888 data. Set the `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field to 0x24 to select RGB888 mode.

Figure 8-56. ISS CSI2 RGB888

### 8.2.5.1.1.4.2.3 ISS CSI2 RGB666

RGB666 data is always output to memory with data expansion. The value of the 14 upper bits is programmable and can be set with an alpha value for computer graphics applications (the `CSI2_CTX_CTRL3_i[29:16]` ALPHA bit field). The line length sent through the CSI2 physical protocol is a multiple of 8 bits. Furthermore, the line length is a multiple of  $9 \times 8$  bits to finish the pixel reconstruction correctly. Figure 8-57 shows the storage format for RGB666 data. Set the `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field to 0x33 to select RGB666 mode.

Figure 8-57. ISS CSI2 RGB666

RGB666

camss-219

### 8.2.5.1.1.4.2.4 ISS CSI2 RGB444

RGB444 data is output to memory with data expansion. When data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications (the [CSI2\\_CTX\\_CTRL3\\_j\[29:16\]](#) ALPHA bit field). [Figure 8-58](#) shows the storage format for RGB444 data. Set the [CSI2\\_CTX\\_CTRL2\\_j\[9:0\]](#) FORMAT bit field to 0xA0 to select RGB444 mode.

**Figure 8-58. ISS CSI2 RGB444**

**8.2.5.1.1.4.2.5 ISS CSI2 RGB555**

RGB555 data is output to memory with data expansion. Figure 8-59 shows the storage format for RGB555 data. Set the `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field to 0xA1 to select RGB555 mode.

**Figure 8-59. ISS CSI2 RGB555**

**8.2.5.1.1.4.3 ISS CSI2 RAW Bayer RGB Operating Modes**

**8.2.5.1.1.4.3.1 ISS CSI2 RAW6**

RAW6 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is a multiple of 8 bits (6-bit image data + 2-bit expansion). Furthermore, the line length is a multiple of 3 × 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 6 is 24, so 3 × 8 bits). Figure 8-60 shows the storage format for RAW6 data. Set the `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field as follows:

- To 0x28 to select RAW6 mode

- To 0x68 for RAW6 + 8-bit expansion
- To 0xE8 for RAW6 + DPCM decompression to 10-bit to video port
- To 0x2A8 for RAW6 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x3A8 for RAW6 + DPCM decompression to 12-bit expanded to 16-bit
- To 0x368 for RAW6 + DPCM decompression to 12-bit to video port

### 8.2.5.1.1.4.3.3 ISS CSI2 RAW8

RAW8 data can be output to memory with or without data expansion. The line length sent through the CSI2 physical layer is always a multiple of 8 bits. [Figure 8-62](#) shows the storage format for RAW8 data. Set the `CSI2_CTX_CTRL2_j[9:0]` FORMAT bit field as follows:

- To 0x2A to select RAW8 mode
- To 0x12A for RAW8 to video port
- To 0x32A for RAW8 + DPCM decompression to 10-bit to video port
- To 0x2AA for RAW8 + DPCM decompression to 10-bit expanded to 16-bit
- To 0x36A for RAW8 + DPCM decompression to 12-bit expanded to 16-bit
- To 0x3AA for RAW8 + DPCM decompression to 12-bit to video port

Figure 8-62. ISS CSI2 RAW8

RAW8

camss-081

8.2.5.1.1.4.3.4 ISS CSI2 RAW10

RAW10 data can be output memory in two formats: with or without data expansion. It can also be sent to the video port. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of  $5 \times 8$  bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 10 is 40, so  $5 \times 8$  bits). Figure 8-63 shows the storage format for RAW10 data. Set the CSI2\_CTX\_CTRL2\_i[9:0] FORMAT bit field as follows:

- To 0x2B to select RAW10 mode
- To 0xAB for RAW10 + 16-bit expansion
- To 0x12F for RAW10 to video port

Figure 8-63. ISS CSI2 RAW10

### 8.2.5.1.1.4.3.5 ISS CSI2 RAW12

RAW12 data can be output to memory in two formats: with or without data expansion. It can also be sent to the video port. If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of  $3 \times 8$  bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 12 is 24, so  $3 \times 8$  bits). [Figure 8-64](#) shows the storage format for RAW12 data. Set the `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field as follows:

- To 0x2C to select RAW12 mode
- To 0xAC for RAW12 + 16-bit expansion
- To 0x12C for RAW12 to video port

**Figure 8-64. ISS CSI2 RAW12**

8.2.5.1.1.4.3.6 ISS CSI2 RAW14

RAW14 data can be output to memory in two formats: with or without data expansion. It can also be sent to the video port. If data expansion is used, the 14-bit data are padded with 0s on a 16-bit word. The line length sent through the CSI2 physical layer is a multiple of 8 bits. Furthermore, the line length is a multiple of 7 x 8 bits to complete the pixel reconstruction correctly (the lowest common multiple of 8 and 14 is 56, so 7 x 8 bits). Figure 8-65 shows the storage format for RAW14 data. Set the CSI2\_CTX\_CTRL2\_i[9:0] FORMAT bit field as follows:

- To 0x2D to select RAW14 mode
- To 0xAD for RAW14 + 16-bit expansion
- To 0x12D for RAW12 to video port

Figure 8-65. ISS CSI2 RAW14

#### 8.2.5.1.1.4.4 ISS CSI2 JPEG8 Operating Modes

The size of a compressed stream can be known in advance. [Figure 8-66](#) shows the format for storing JPEG8 data.

Transmitter

Receiver

#### 8.2.5.1.1.4.5 ISS CSI2 Generic Format

The CSI2 receiver supports a generic format to send data to memory and/or the video port. The generic mode is entered by setting the `CSI2_CTX_CTRL1_i[30]` GENERIC bit. The `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field defines how the data stream is decoded. When generic mode is enabled (GENERIC = 1), the MIPI data type code is ignored and data is decoded using the FORMAT bit. Whatever the MIPI data type code, it is ignored (the data stream is processed even if the FORMAT bit does not match the MIPI data type code.) When generic mode is not used (GENERIC = 0), the data stream is processed only when the MIPI data type code matches the FORMAT setting of the enabled context. If not matched, the data stream is not processed by the CSI2 engine. Only the virtual channel information is used to map a received data stream to a context. Software must ensure that a MIPI virtual channel used in generic mode is mapped only to a single context.

[Figure 8-67](#) shows the ISS CSI2 generic format.

**Figure 8-67. ISS CSI2 Generic Format**

ISS CSI2 Generic: `CSI2_CTX_CTRL1_i[30]` GENERIC = 0x1

### 8.2.5.2 ISS CSI2 Integration

Figure 8-68 is an overview of the integration of the CSI2-A/CSI2-B interface in the device. The figure is the top-level block diagram of the CSI2-A/CSI2-B receiver. The CSI2-A/CSI2-B receiver receives the serial data coming from a CSI2 compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the video port or the ISS interconnect interface.

Figure 8-68. ISS CSI2-A/CSI2-B Integration

camss-352b

The CSI2-A/CSI2-B receiver can send data directly to system memory using the master port or send it to the camera ISP using the video port.

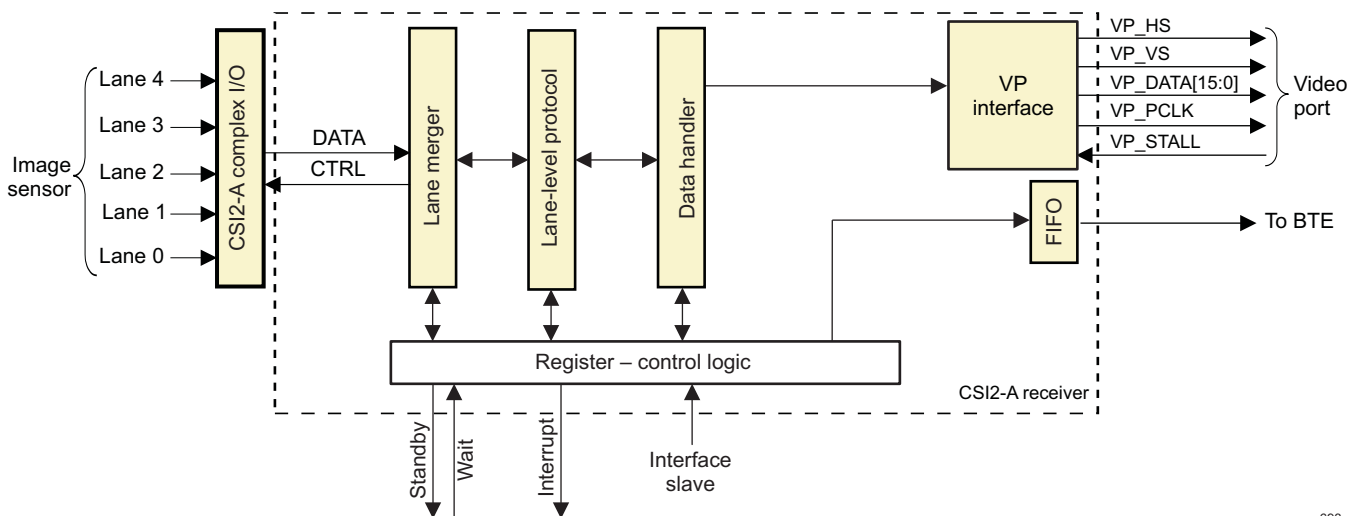

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

### 8.2.5.3 ISS CSI2 Functional Description

#### 8.2.5.3.1 ISS CSI2 Overview

Figure 8-69 is the CSI2-A receiver block diagram (it assumes there are four CSI2 image sensor data lines). The only difference for CSI2-B is the number of lanes coming into the complex I/O. The CSI2 receiver receives the byte data coming from a CSI2 D-PHY receiver (up to four data pairs), converts it to byte stream, detects and corrects errors, extracts the virtual channel ID, detects and extracts the synchronization codes, reformats the data, and outputs it through the video port or the ISS interconnect interface. Data communication between CSI2 and ISP is done through the video port.

**Figure 8-69. ISS CSI2-A Receiver Block Diagram**

camss-693

#### 8.2.5.3.2 ISS CSI2 Features

The CSI2 receiver is a master on the L3 interconnect for storing data in memory and a slave on the level 4 (L4) interconnect for register access.

The main features of the CSI2 receiver are:

- Transfer pixels and data received by the CSI2 PHY to the system memory or video processor
- Unidirectional data link
- Supports up to four data-configurable links in addition to the clock signaling (minimum of one data link and maximum of four depending on the speed)
- Data merger for two, three, or four data lane configurations
- Error detection and correction by the protocol engine
- DMA engine integrated with dedicated FIFO
- 1D and 2D addressing modes
- Up to eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- JPEG support for unknown length transfer (no extraction of the thumbnail)
- Supports all primary and secondary MIPI-defined formats (RGB, RAW, and YUV)
- Storage in progressive mode for interlaced stream (using line numbering)
- Conversion to the RGB formats
- Decompressions of the RAW formats
- RAW frame transcoding, including DPCM and A-Law compression
- Fully configurable interface of the complex PHY I/O: position of the clock and data and order of  $\pm$  differential signals for each pair

### 8.2.5.3.3 ISS CSI2 Functional Description

#### 8.2.5.3.3.1 ISS CSI2 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer.

The maximum CSI2 receiver data transfer capacity is 1000 Mbps per data lane.

Data-clock signaling consists of two to five differential signal pairs: from one to four data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the dual-data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 complex I/O receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or clock lane with a restriction to the fourth line, which can only be data (see [Section 8.2.3.1, ISS CSI2 PHY Overview](#)). The clock/data lane must be configured before transmission to indicate the byte order, while merging the received bytes into a byte stream shows the reachable speed per data lane function of data lane numbers.

Lanes are configured through the [CSI2\\_COMPLEXIO\\_CFG](#) registers for CSI2-A and CSI2-B PHY, respectively. The [CSI2\\_COMPLEXIO\\_CFG\[2:0\] CLOCK\\_POSITION](#) bit field and the [CSI2\\_COMPLEXIO\\_CFG\[3\] CLOCK\\_POL](#) bit configure which lane transmits the clock and define its polarity. [DATAI\\_POSITION](#) and [DATAI\\_POL](#) configure the data lanes and their polarity, where *l* is the number of the data lane (*l* = 1 to 4). When the [DATAI\\_POSITION](#) field is set to 0, data lane *l* is not used.

#### CAUTION

Lane 4 (position 5) supports only data. The [CLOCK\\_POSITION](#) must not be set at position 5.

#### 8.2.5.3.3.2 ISS CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

##### 8.2.5.3.3.2.1 ISS CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for a long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bitstream. If the ECC does not match, an interrupt is triggered to the host central processing unit (CPU).

For long and short packets, the correction is always done if there is only one error per packet header.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. [Table 8-146](#) describes the field in which events are logged. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2\\_IRQENABLE](#) and [CSI2\\_CTX\\_IRQENABLE\\_i](#) registers to prevent event generation at a higher level.

**Table 8-146. ISS CSI2 ECC Event Logging**

	Short Packet	Long Packet
With correction	Global <a href="#">CSI2_IRQSTATUS</a> [12] ECC_CORRECTION_IRQ	Context <a href="#">CSI2_CTX_IRQSTATUS_i</a> [8] ECC_CORRECTION_IRQ
Without correction	Global <a href="#">CSI2_IRQSTATUS</a> [11] ECC_NO_CORRECTION_IRQ	Global <a href="#">CSI2_IRQSTATUS</a> [11] ECC_NO_CORRECTION_IRQ

The ECC check can be disabled (short and long packet) by setting the [CSI2\\_CTRL](#)[2] ECC\_EN bit to 0. Setting the bit to 1 enables the ECC check.

#### 8.2.5.3.3.2 ISS CSI2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an interrupt is triggered to the host CPU.

CRC errors are logged in the CS\_IRQ field of the corresponding context register, [CSI2\\_CTX\\_IRQSTATUS\\_i](#). Logging cannot be disabled, but users can set the corresponding bit in the [CSI2\\_CTX\\_IRQENABLE\\_i](#) register to prevent event generation at a higher level.

The CRC can be disabled for a specific context by setting the [CSI2\\_CTRL](#)[5] CS\_EN bit to 0. Setting the bit to 1 enables the CRC.

#### 8.2.5.3.3.3 ISS CSI2 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled. Then, the short packet is written in the [CSI2\\_SHORT\\_PACKET](#)[23:0] SHORT\_PACKET bit field. The ECC field is deleted from the short packet. [Figure 8-70](#) shows the SHORT\_PACKET bit field format.

**Figure 8-70. ISS CSI2 SHORT\_PACKET Bit Field Format**

When a short packet is stored, an event is logged in the [CSI2\\_IRQSTATUS](#)[13] SHORT\_PACKET\_IRQ bit. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2\\_IRQENABLE](#) register to prevent event generation at a higher level.

The application reads the [CSI2\\_SHORT\\_PACKET](#) register before the next short packet with a code from 0x8 to 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

#### 8.2.5.3.3.4 ISS CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The virtual channels separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

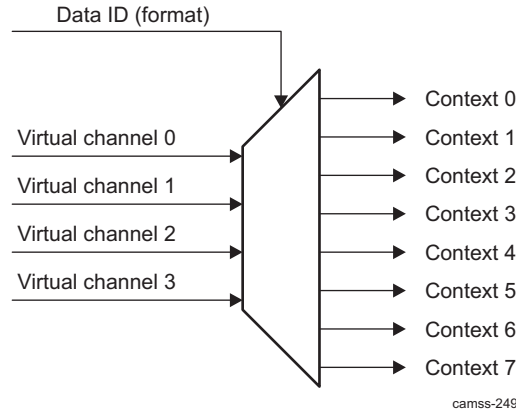

The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts with their events to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following bit fields permit configuration of a context:

- [CSI2\\_CTX\\_CTRL2\\_i\[12:11\] VIRTUAL\\_ID](#): Configures the virtual ID linked to the current context
- [CSI2\\_CTX\\_CTRL2\\_i\[9:0\] FORMAT](#): Configures the data format linked to the current context

Figure 8-71 shows the relationships between virtual channels and contexts.

**Figure 8-71. ISS CSI2 Virtual Channel to Context**

Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by setting the [CSI2\\_CTX\\_CTRL1\\_i\[0\] CTX\\_EN](#) bit to 1; setting this bit to 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the [CSI2\\_CTX\\_CTRL1\\_i\[15:8\] COUNT](#) bit field. Acceptable values are 0 to 255; 0 stands for infinite capture (no count). After each frame is acquired, the count value is decremented by 1. When the count value reaches 0, the [CSI2\\_CTX\\_IRQSTATUS\\_i\[6\] FRAME\\_NUMBER\\_IRQ](#) event is set and the CTX\_EN bit is set to 0. To write a value in the COUNT bit field, the [CSI2\\_CTX\\_CTRL1\\_i\[4\] COUNT\\_UNLOCK](#) bit must be set to 1. If the value of the COUNT\_UNLOCK bit is 0, a write in the COUNT bit field has no effect.

The [CSI2\\_CTX\\_CTRL3\\_i\[15:0\] LINE\\_NUMBER](#) bit field configures the generation of the [CSI2\\_CTX\\_IRQSTATUS\\_i\[7\] LINE\\_NUMBER\\_IRQ](#) event. The [CSI2\\_CTX\\_CTRL1\\_i\[1\] LINE\\_MODULO](#) bit configures how the LINE\_NUMBER event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo LINE\_NUMBER (the event can be generated more than once in a frame).

During a frame capture, the [CSI2\\_CTX\\_CTRL2\\_i\[31:16\] FRAME\\_NUMBER](#) bit field shows the number that identifies the frame received.

### 8.2.5.3.3.5 ISS CSI2 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration is common to the eight channels and is defined in the [CSI2\\_CTRL](#) register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports:

- 1D addressing mode (no address line offset, [CSI2\\_CTX\\_DAT\\_OFST\\_i = 0](#))
- 2D addressing mode (address line offset different than 0, [CSI2\\_CTX\\_DAT\\_OFST\\_i = 0](#))

The burst size is defined in the [CSI2\\_CTRL\[6:5\] BURST\\_SIZE](#) bit field and the [CSI2\\_CTRL\[16\] BURST\\_SIZE\\_EXPAND](#) bit. The DMA uses the burst size or smaller sizes down to single open-core protocol (OCP) writes depending on the alignment at the end of lines. The DMA engine can handle burst requests. When the burst requests can be used, as soon as one burst of data is present in the FIFO, the DMA engine initiates a burst write. The burst size is defined in the [CSI2\\_CTRL\[6:5\] BURST\\_SIZE](#) bit field and the [CSI2\\_CTRL\[16\] BURST\\_SIZE\\_EXPAND](#) bit.

---

**NOTE:** Unless there are specific requirements, CSI2 (also applies to all other ISS initiators) must be configured to use only a burst size of 128 bytes and nonposted writes.

---

When single requests must be used, as soon as one element (the size depends on the data type and the post-processing: DPCM, EXT, etc.) is present in the FIFO, the DMA engine initiates a single write.

Interleave mode is dedicated by the CSI2 receiver only when the line numbers are received (short packets). The line number is used to calculate the start address of the line.

The DMA starts to write in memory using the [CSI2\\_CTX\\_DAT\\_PING\\_ADDR\\_i\[31:5\] ADDR](#) bit field for the first frame to be transferred, and then uses the [CSI2\\_CTX\\_DAT\\_PONG\\_ADDR\\_i\[31:5\] ADDR](#) bit field and the ping address alternately. Thus, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The [CSI2\\_CTX\\_CTRL1\\_i\[3\] PING\\_PONG](#) status bit indicates whether the ping address ([CSI2\\_CTX\\_DAT\\_PING\\_ADDR\\_i](#)) or the pong address ([CSI2\\_CTX\\_DAT\\_PONG\\_ADDR\\_i](#)) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the [CSI2\\_CTRL\[0\] IF\\_EN](#) bit, the pixel data is written in the ping buffer and the [CSI2\\_CTX\\_CTRL1\\_i\[3\] PING\\_PONG](#) bit = PONG. When the number of FECs received equals the value programmed in the [CSI2\\_CTX\\_CTRL1\\_i\[23:16\] FEC\\_NUMBER](#) bit field, the pixel data are written in the pong buffer and [CSI2\\_CTX\\_CTRL1\\_i\[3\] PING\\_PONG](#) = PING. [CSI2\\_CTX\\_CTRL1\\_i\[3\] PING\\_PONG](#) toggles after the [CSI2\\_CTX\\_CTRL1\\_i\[23:16\] FEC\\_NUMBER](#) FEC sync code with the virtual channel ID defined is received in the [CSI2\\_CTX\\_CTRL2\\_i\[12:11\] VIRTUAL\\_ID](#) bit field.

The [CSI2\\_CTX\\_CTRL1\\_i\[23:16\] FEC\\_NUMBER](#) bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the [PING\\_PONG](#) buffer.

#### 8.2.5.3.3.5.1 ISS CSI2 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the [CSI2\\_CTX\\_DAT\\_OFST\\_i\[31:5\] OFST](#) bit field:

- If [OFST](#) = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the value of [OFST](#) sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

```
@Line0 = CSI2_CTX_DAT_PING_ADDR_i
@Line1 = @Line0 + CSI2_CTX_DAT_OFST_i
@Line2 = @Line1 + CSI2_CTX_DAT_OFST_i
```

For the pong frame:

```
@Line0 = CSI2_CTX_DAT_PONG_ADDR_i
@Line1 = @Line0 + CSI2_CTX_DAT_OFST_i
@Line2 = @Line1 + CSI2_CTX_DAT_OFST_i
```

#### 8.2.5.3.3.5.2 ISS CSI2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

For the ping frame:

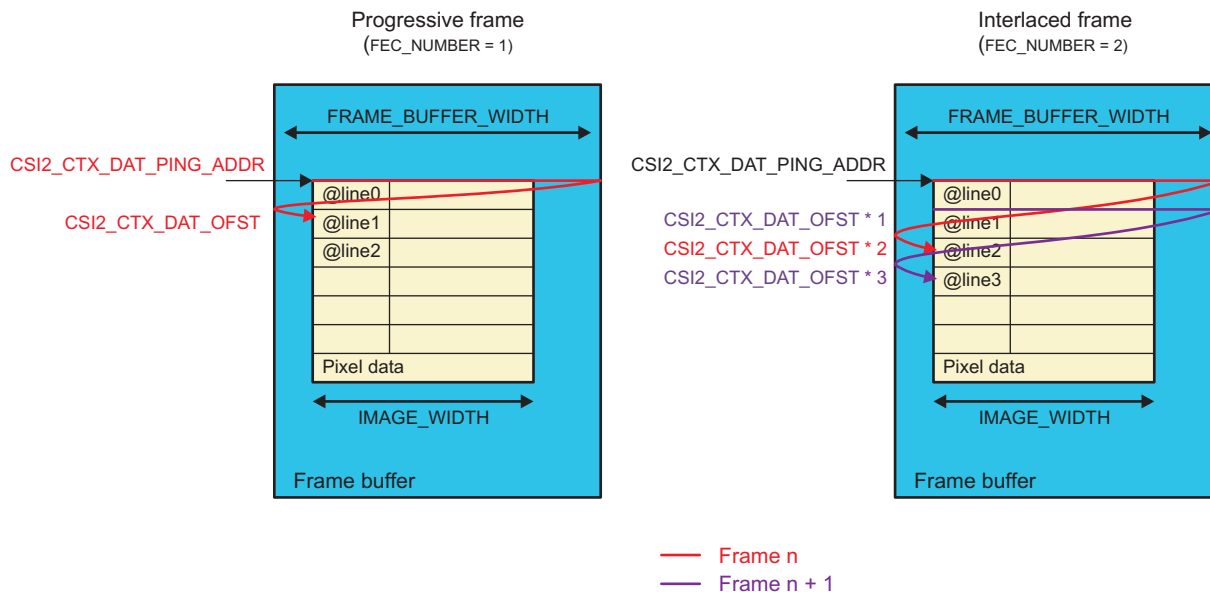

```
@LineX = CSI2_CTX_DAT_PING_ADDR_i + CSI2_CTX_DAT_OFST_i * Line_Number
```

For the pong frame:

$$\text{@LineX} = \text{CSI2\_CTX\_DAT\_PONG\_ADDR}_i + \text{CSI2\_CTX\_DAT\_OFST}_i * \text{Line\_Number}$$

Figure 8-72 shows how data are stored in memory regarding the DMA configuration.

**Figure 8-72. ISS CSI2 Pixel Data Destination Setting in Progressive and Interlaced Mode**

camss-250

The burst size is defined in the [CSI2\\_CTRL\[6:5\]](#) BURST\_SIZE bit field for bursts up to 16 × 64 bits or the [CSI2\\_CTRL\[16\]](#) BURST\_SIZE\_EXPAND bit for 16 × 128-bit bursts. It can be changed only while the [CSI2\\_CTRL\[0\]](#) IF\_EN bit is reset to 0. The recommended value is the [CSI2\\_CTRL\[16\]](#) BURST\_SIZE\_EXPAND bit set to 1, which defines a burst of 16 × 64 bits (the maximum value); otherwise, by default it is set to 8 × 64 bits. When the BURST\_SIZE\_EXPAND bit is set, the BURST\_SIZE setting has no effect. The DMA uses nonposted writes by default. The [CSI2\\_CTRL\[13\]](#) NON\_POSTED\_WRITE bit must be set to 1 to match DMA default configuration. It can be changed only while the [CSI2\\_CTRL\[0\]](#) IF\_EN bit is reset to 0.

### 8.2.5.3.3.6 ISS CSI2 MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of CSI2 real-time traffic, when required, based on the fullness of the CSI2 DMA read and write buffers. Programmable buffer thresholds indicate when the local MFLAG signal is generated. The MFLAG signal is then provided to the L3 interconnect for granting or prioritizing OCP requests. The out band CSI2 MFLAG signal is asynchronous to any on-going OCP transaction. The threshold corresponds to the fullness of DMA buffer, and is defined by the following threshold parameters:

- High threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted). The value is set in the [CSI2\\_CTRL\[22:20\]](#) MFLAG\_LEVH register.
- Low threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted). The value is set in the [CSI2\\_CTRL\[19:17\]](#) MFLAG\_LEVL register.

### 8.2.5.3.3.7 ISS CSI2 Transcoding

Image transcoding is used mainly to reduce memory footprint and bandwidth when:

- The sensor does not support DPCM compression. In fact, A-Law and DPCM compressed pixels occupy only 6, 7, or 8 BPP of storage.
- Digital zoom is used
  - Data that is not going to be used by further processing does not need to be stored in system

memory.

- Pixels cannot be accessed from random locations in a DPCM-compressed frame. Transcoding avoids memory-to-memory processing of unused pixels.

Figure 8-73 shows the logical representation of the image transcoding operation.

- Data is extracted from the CSI2 stream by the protocol engine.
- It is DPCM decompressed if necessary. That is the case when the received stream is DPCM-compressed and transcoding has been enabled using the `CSI2_CTX_CTRL1_i[27:24]` TRANSCODE bit field.
- Data sent to the video port cannot be compressed: it is intended to be processed by the ISS ISP. Data sent to system memory can be optionally compressed.
- Internal data are aligned on MSB when they enter the cropping stage. For example:
  - 4 LSBs are 0s when RAW10 data are handled.
  - 2 LSBs are 0s when RAW12 data are handled.

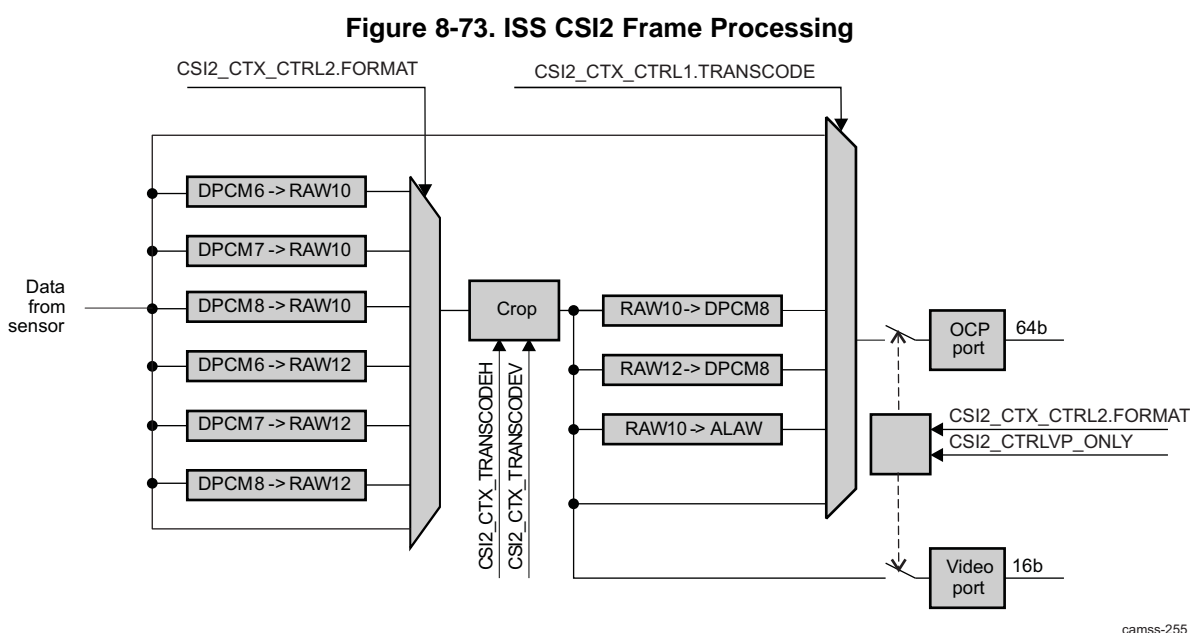

Table 8-147 shows the input format provided to the cropping engine for a given pixel format provided by the sensor. Formats not listed in the table are not supported for transcoding. The FORMAT and Corresponding Setting Value column corresponds to the value set in the `CSI2_CTX_CTRL2_i[9:0]` FORMAT register.

**Table 8-147. ISS CSI2 Supported Transcoding Input Formats**

CSI2_CTX_CTRL2_i[9:0] FORMAT and Corresponding Setting Value		Cropping Engine Input Format	DPCM Decomposition Enabled	Video Port Enabled
0x028	RAW6	RAW6		
0x068	RAW6 + EXP8			
0x029	RAW7	RAW7		
0x069	RAW7 + EXP8			
0x02A	RAW8	RAW8		
0x12A	RAW8 + VP			Yes
0x02B	RAW10	RAW10		
0x0AB	RAW10 + EXP16			
0x0E8	RAW6 + DPCM10 + VP		Yes	Yes
0x12F	RAW10 + VP			Yes

**Table 8-147. ISS CSI2 Supported Transcoding Input Formats (continued)**

CSI2_CTX_CTRL2_i[9:0] FORMAT and Corresponding Setting Value		Cropping Engine Input Format	DPCM Decomposition Enabled	Video Port Enabled
0x229	RAW7 + DPCM10 + EXP16		Yes	
0x2A8	RAW6 + DPCM10 + EXP16		Yes	
0x2AA	RAW8 + DPCM10 + EXP16		Yes	
0x329	RAW7 + DPCM10 + VP		Yes	Yes
0x32A	RAW8 + DPCM10 + VP		Yes	Yes
0x2Cn	USER_DEFINED_BYTE_DATA + DPCM10 + EXP16		Yes	
0x34n	USER_DEFINED_BYTE_DATA + DPCM10 + VP		Yes	Yes
0x02C	RAW12		RAW12	
0x0AC	RAW12 + EXP16			
0x12C	RAW12 + VP			Yes
0x35A	RAW8 DPCM12 + EXP16	Yes		
0x3AA	RAW8 DPCM12 + VP	Yes		Yes
0x1Cn	USER_DEFINED_BYTE_DATA + DPCM12 + EXP16	Yes		
0x14n	USER_DEFINED_BYTE_DATA + DPCM12 + VP	Yes		Yes
0x3A8	RAW6 + DPCM12 + EXP16	Yes		
0x368	RAW6 + DPCM12 + VP	Yes		Yes
0x369	RAW7 + DPCM12 + EXP16	Yes		
0x3A9	RAW7 + DPCM12 + VP	Yes		Yes
0x02D	RAW14	RAW14		
0x0AD	RAW14 + EXP16			
0x12D	RAW14 + VP			Yes

Image cropping parameters are controlled by software. Figure 8-74 shows the cropping operation.

**Figure 8-74. ISS CSI2 Frame Cropping**

**CAUTION**

Hardware does not check for validity of the settings. The following rules must be respected:

- `CSI2_CTX_TRANSCODEH_i[12:0]` HSKIP + `CSI2_CTX_TRANSCODEH_i[28:16]` HCOUNT  $\leq$  image width
- `CSI2_CTX_TRANSCODEV_i[12:0]` VSKIP + `CSI2_CTX_TRANSCODEV_i[28:16]` VCOUNT  $\leq$  image height

Furthermore, the `CSI2_CTX_TRANSCODEH_i[28:16]` HCOUNT bit field must comply with the following alignment constraints; otherwise, undefined behavior occurs. Table 8-148 shows the transcode alignment constraints

**Table 8-148. ISS CSI2 Transcode Alignment Constraints**

CSI2_CTX_CTRLi[27:24] TRANSCODE Value	Transcode	HCOUNT Must Be Multiple of
0x0	Disabled	1
0x1	DPCM10 RAW8	1
0x2	DPCM12 RAW8	1
0x3	ALAW10 RAW8	1
0x4	RAW8	1
0x5	RAW10 + EXP16	1
0x6	RAW10	4
0x7	RAW12 + EXP16	1
0x8	RAW12	2
0x9	RAW10 + EXP16	4

The `CSI2_CTX_CTRL1_i[28]` HSCALE configuration register enables horizontal downscaling of RAW data. It reduces the horizontal size and pixel clock by a factor of 2. The scaler uses a 2-tap horizontal filter operating on samples of the same color plane. The coefficients are:  $[1/2 ; 0 ; 1/2]$

Figure 8-75 shows the scaler operation.

**Figure 8-75. ISS CSI2 Horizontal Scaler**

camss-710u

The scaler can send data to the video port or the interface port. When data goes to the video port, no additional alignment constraints apply. But when data goes to the interface port, HCOUNT/2 must comply with the constraints from Table 8-148 (for example, for RAW10, HCOUNT must be a multiple of 8).

Table 8-149 lists possible combinations of input and output formats supported by the transcoding engine. The Transcode column corresponds to the `CSI2_CTX_CTRL1_i[27:24]` TRANSCODE bit field of a context.

**Table 8-149. ISS CSI2-Supported Transcoding Output Formats**

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported
RAW6	0	Disabled	Yes	RAW10	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	Yes
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	Yes
	4	RAW8			4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	Yes
	6	RAW10			6	RAW10	Yes
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	
	9	RAW14		9	RAW14		
RAW7	0	Disabled	Yes	RAW12	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	
	2	DPCM12 RAW8			2	DPCM12 RAW8	Yes
	3	ALAW10 RAW8			3	ALAW10 RAW8	
	4	RAW8			4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	Yes
	8	RAW12			8	RAW12	Yes
	9	RAW14		9	RAW14		
RAW8	0	Disabled	Yes	RAW14	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	
	4	RAW8	Yes		4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	
	8	RAW12			8	RAW12	
	9	RAW14		9	RAW14	Yes	

RAW pixels are packed into 64-bit words sent to the OCP master port, as defined in:

- [Section 8.2.5.1.1.4.3.3, ISS CSI2 RAW8](#)
- [Section 8.2.5.1.1.4.3.4, ISS CSI2 RAW10](#)
- [Section 8.2.5.1.1.4.3.5, ISS CSI2 RAW12](#)
- [Section 8.2.5.1.1.4.3.6, ISS CSI2 RAW14](#)

For RAW10 and RAW12, software can choose among packed and nonpacked storage. A-Law and DPCM-compressed pixels are stored as RAW8 data: each RAW8 container holds a compressed data point.

Similarly, RAW data is sent over the video port, as described in:

- [Section 8.2.5.1.1.4.3.3, ISS CSI2 RAW8](#)
- [Section 8.2.5.1.1.4.3.4, ISS CSI2 RAW10](#)
- [Section 8.2.5.1.1.4.3.5, ISS CSI2 RAW12](#)
- [Section 8.2.5.1.1.4.3.6, ISS CSI2 RAW14](#)

Enabling of the OCP/video port is controlled by the [CSI2\\_CTX\\_CTRL2\\_i\[9:0\] FORMAT](#) bit field and the [CSI2\\_CTRL\[11\] VP\\_ONLY\\_EN](#) and [CSI2\\_CTX\\_CTRL1\\_i\[2\] VPFORCE](#) bits.

To enable transcoding, software configures the context normally and also configures the framing using the [CSI2\\_CTX\\_TRANSCODEV\\_i](#) and [CSI2\\_CTX\\_TRANSCODEH\\_i](#) registers. Software defines the after transcoding with the [CSI2\\_CTX\\_CTRL1\\_i\[27:24\]](#) TRANSCODE bit field.

### 8.2.5.3.3.8 ISS CSI2 EndOfFrame and EndOfLine (EOF and EOL) Pulses

The CSI2 receiver generates two signals to qualify the last pixel of a frame and the last pixel of a line to the TCTRL. It is active during or after the adequate interface bridge transaction and becomes inactive before the first transaction of the next line. Software can enable/disable generation of those signals for each context using the [CSI2\\_CTX\\_CTRL1\\_i\[7\]](#) EOF\_EN and [CSI2\\_CTX\\_CTRL1\\_i\[6\]](#) EOL\_EN bits. When data is sent to both OCP and video ports, the EOL/EOF timing defined for the OCP port is used.

### 8.2.5.3.3.9 ISS CSI2 Data Decompression

The data compression technique used is DPCM and PCM.

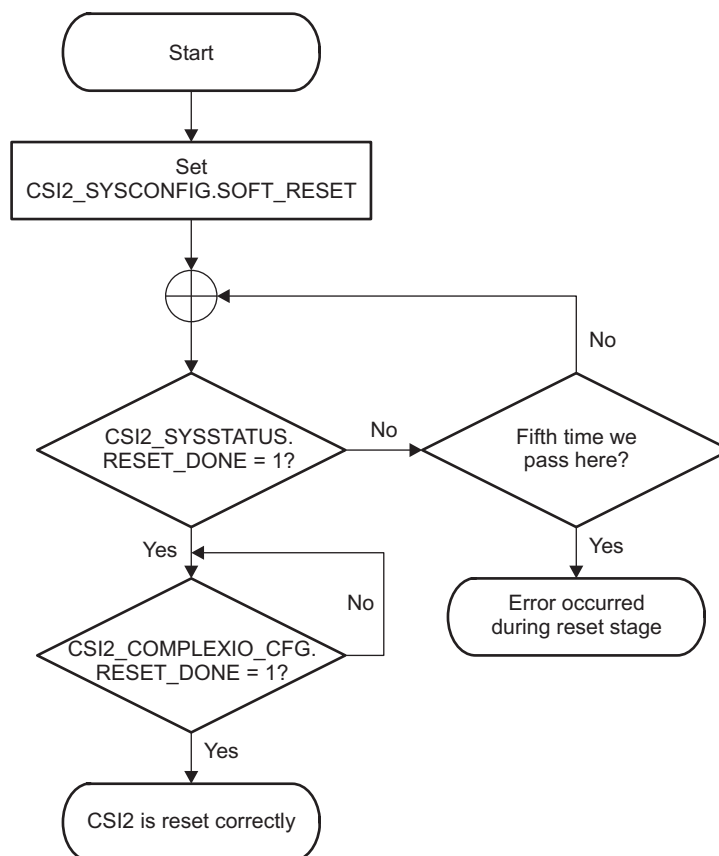

To select the DPCM decompression predictor for the CSI2 Interface, set the [CSI2\\_CTX\\_CTRL2\\_i\[10\]](#) DPCM\_PRED bit to 1 for simple predictor or to 0 for advanced predictor.

## 8.2.5.4 ISS CSI2 Programming Model

### 8.2.5.4.1 ISS CSI2 Programming Reset Management

The CSI2 receiver accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the complex I/O (A or B) and has the same effect as a hardware reset. [Figure 8-76](#) shows how to reset CSI2 globally.

**Figure 8-76. ISS CSI2 Receiver Global Reset Flow Chart**

camss-252

---

**NOTE:** Before setting the software reset bit to 1 in the [CSI2\\_SYSCONFIG](#) register, the user must have access to a CSI2 receiver register.

---

**NOTE:** The [CSI2\\_COMPLEXIO\\_CFG](#)[29] RESET\_DONE bit is set to 1 only after the initialization of the CSI2 receiver, CSI2 complex I/O, and external camera completes.

---

#### 8.2.5.4.2 ISS CSI2 Programming Enable Video/Picture Acquisition

Before using the receiver, a CSIPHY initialization in CSI2 mode must be made for CSI2-A CAMERARX, which is associated with the CSI2 receiver. See [Section 8.2.3.2.2, ISS CSI2 PHY and Link Initialization Sequence](#). To start a video/picture acquisition, perform the steps listed in [Table 8-150](#).

**Table 8-150. ISS CSI2 Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Reset the CSI2 receiver.	See <a href="#">Section 8.2.5.4.1, Reset Management</a> .	
Configure the module power management. The module tries to enter smart-standby mode during the vertical blanking period. The <a href="#">CSI2_SYSCONFIG</a> [0] AUTO_IDLE bit keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity.	<a href="#">CSI2_SYSCONFIG</a> [13:12] MSTANDBY_MODE	0x2
Configure the interrupt generation as required. To enable context and/or complex I/O event reporting, enable the corresponding bit field in the <a href="#">CSI2_IRQENABLE</a> register. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level.	<a href="#">CSI2_IRQSTATUS</a> and <a href="#">CSI2_IRQENABLE</a>	
Configure the complex I/O interrupt generation as required. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level.	<a href="#">CSI2_COMPLEXIO_IRQSTATUS</a> and <a href="#">CSI2_COMPLEXIO_IRQENABLE</a> )	
Start complex I/O: Set the <a href="#">CSI2_COMPLEXIO_CFG</a> [28:27] PWR_CMD bit field to 0x1 to pass the complex I/O to the ON state, and then check that the state status reaches the ON state ( <a href="#">CSI2_COMPLEXIO_CFG</a> [26:25] PWR_STATUS = 0x1) (for complex I/O A).	<a href="#">CSI2_COMPLEXIO_CFG</a> [28:27] PWR_CMD	0x1
Configure the complex I/O: <ul style="list-style-type: none"> <li>The complex I/O is fully functional with <a href="#">CSI2_COMPLEX_CFG</a> set at its reset value.</li> <li><a href="#">CSI2_COMPLEX_CFG</a> must be changed according to the data rate being used.</li> </ul>	<a href="#">CSI2_COMPLEXIO_CFG</a>	
Set RXMODE and STOPSTATE FSM to RXMODE state. Users can also configure the delay for the FSM to return from RXMODE to NORXMODE when all lines reach STOPSTATE.	<a href="#">CSI2_TIMING</a> [15] FORCE_RX_MODE_IO1	0x1
Activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error).	<a href="#">CSI2_CTRL</a> [2] ECC_EN	0x1
Start the CSI2 receiver.	<a href="#">CSI2_CTRL</a> [0] IF_EN	0x1
Configure the different contexts to be used.		
Link the context to a virtual channel and a data type.	See <a href="#">Section 8.2.5.4.6, Linking a Context to a Virtual Channel and a Data Type</a> .	
Set the FEC_NUMBER bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see <a href="#">Section 8.2.5.3.3.5, DMA Engine</a> .	<a href="#">CSI2_CTX_CTRL1_i</a> [26:23] FEC_NUMBER	0x1 or 0x2

**Table 8-150. ISS CSI2 Global Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Capture an infinite number of frames (until the interface or the context is disabled).	<a href="#">CSI2_CTX_CTRL1_i[15:8] COUNT</a> and <a href="#">CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK</a>	0x0
Enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the <a href="#">CSI2_CTX_IRQSTATUS_i[5] CS_IRQ</a> bit).	<a href="#">CSI2_CTX_CTRL1_i[5] CS_EN</a>	
Configure the DMA engine for the current channel: Configure the ping and pong addresses.	<a href="#">CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR</a> and <a href="#">CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR</a>	
Set the <a href="#">CSI2_CTX_DAT_OFST_i[15:5] OFST</a> bit field to 0x0 so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal).	<a href="#">CSI2_CTX_DAT_OFST_i[15:5] OFST</a>	
Keep the ALPHA setting at its reset value (0x0) for RGB padding.	<a href="#">CSI2_CTX_CTRL3_i[29:16] ALPHA</a>	
Enable the contexts.	<a href="#">CSI2_CTX_CTRL1_i[0] CTX_EN</a>	0x1

#### 8.2.5.4.3 ISS CSI2 Programming Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by setting the [CSI2\\_CTX\\_CTRL1\\_i\[0\] CTX\\_EN](#) bit to 0. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.
- Disable the CSI2 receiver interface by setting the [CSI2\\_CTRL\[0\] IF\\_EN](#) bit to 0. This can have an immediate effect if the [CSI2\\_CTRL\[3\] FRAME](#) bit is set to 0, or it can be effective after all the enabled contexts receive the FEC if the [CSI2\\_CTRL\[3\] FRAME](#) bit is set to 1.

#### 8.2.5.4.4 ISS CSI2 Programming Capture a Finite Number of Frames

The CSI2 receiver can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the steps listed in [Table 8-151](#).

**Table 8-151. ISS CSI2 Capture a Finite Number of Frames**

Step	Bit Field	Value
Enable a write to the COUNT bit field.	<a href="#">CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK</a>	0x1
Set the bit field to the number of frames the CSI2 receiver must capture.	<a href="#">CSI2_CTX_CTRL1_i[15:8] COUNT</a>	Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture.
Disable a write to the COUNT bit field.	<a href="#">CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK</a>	0x0

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. Software reads the COUNT bit field to know how many frames must still be captured.

The COUNT bit can be updated during capture if the COUNT\_UNLOCK bit is set to 1.

#### 8.2.5.4.5 ISS CSI2 Programming a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the [CSI2\\_CTX\\_CTRL3\\_i\[15:0\] LINE\\_NUMBER](#) bit field. The event can be generated once or multiple times per frame, depending on the value of the [CSI2\\_CTX\\_CTRL1\\_i\[1\] LINE\\_MODULO](#) bit:

- If the LINE\_MODULO bit = 0, the event is generated when the line number corresponding to the LINE\_NUMBER bit field is received.
- If the LINE\_MODULO bit = 1, the event is generated when the line number received corresponds to a multiple of the LINE\_NUMBER value (LINE\_NUMBER is used as a modulo).

### 8.2.5.4.6 ISS CSI2 Programming a Context to a Virtual Channel and a Data Type

The CSI2 receiver supports eight contexts and the CSI2 protocol defines four virtual channels. Therefore, a CSI2 receiver context can be associated with a virtual channel and a data type. Virtual channels are defined by a 2-bit field. Valid data types for the CSI2 receiver with their associated values are described in the [CSI2\\_CTX\\_CTRL2\\_i\[9:0\]](#) FORMAT bit field.

For each context, a [CSI2\\_CTX\\_CTRL2\\_i](#) register defines with which channel and data type the context is associated:

- The VIRTUAL\_ID bit field defines the associated virtual ID transported by the CSI2 protocol from the camera sensor.
- The FORMAT bit field defines the associated data type. The data type is a combination of the data type transported by the CSI2 protocol and the type of storage in memory. A given data type (RGB888) can be stored in memory in different ways (RGB888 or RGB888 + EXP32). Therefore, the FORMAT bit field also defines how DMA stores data in memory.

For example, for the current context to capture a frame from virtual channel 2 and data type RAW12 with data expansion (RAW12 + EXP16), write the value 0x10AC (0x2 11 + 0xAC) in the 16 LSBs of the [CSI2\\_CTX\\_CTRL2\\_i](#) register.

### 8.2.5.4.7 ISS CSI2 Programming Progressive and Interleaved Frame Configuration

The CSI2 receiver can treat progressive and interlaced frames. There is no progressive or interleaved mode, but the [CSI2\\_CTX\\_CTRL1\\_i\[23:16\]](#) FEC\_NUMBER bit field controls the number of FECs before swapping to the other (ping or pong) buffer. Therefore, two modes are possible:

- FEC\_NUMBER = 1: This is equivalent to progressive mode. After a FEC on the context, the current buffer is switched (ping to pong or pong to ping). The image in the memory buffer consists of one transmitted frame.
- FEC\_NUMBER 1: The current buffer is switched (ping to pong or pong to ping) after the FEC\_NUMBER FEC is received for the context. The image in the memory buffer consists of the FEC\_NUMBER transmitted frame.

For more information about how data is stored in memory through the DMA, see [Section 8.2.5.3.3.5, DMA Engine](#).

---

**NOTE:** If FEC\_NUMBER 1, the camera sensor must send the line number information with the current line. Otherwise, the CSI2 receiver cannot calculate each line address.

---

### 8.2.5.4.8 ISS CSI2 Programming Progressive and Interleaved Frame Configuration

[Table 8-152](#) lists the procedure to enable debug mode.

**Table 8-152. ISS CSI2 Enable Debug Mode**

Step	Bit	Value
Enable debug mode.	<a href="#">CSI2_CTRL[7]</a> DBG_EN	0x1

- During debug mode the input does not come from the CSI2 receiver interface but from the [CSI2\\_DBG\\_H](#) and [CSI2\\_DBG\\_P](#) registers. The full CSI2 receiver function can be debugged in debug mode. Full 32-bit values must always be written to the [CSI2\\_DBG\\_H](#) register. The [CSI2\\_CTRL\[0\]](#) IF\_EN bit has no affect during debug mode. To reset the FIFO in case of overflow, the [CSI2\\_CTRL\[7\]](#) DBG\_EN bit must be reset to 0, and the interface must be enabled by setting the [CSI2\\_CTRL\[0\]](#) IF\_EN bit to 0x1.
- The [CSI2\\_DBG\\_H](#) register is used to provide short packet and long packet headers.
- The [CSI2\\_DBG\\_P](#) register is used to provide long packet payload.

The following examples apply to the [CSI2\\_DBG\\_H](#) register:

- The sync codes for virtual channel 0 are written as [CSI2\\_DBG\\_H](#) = 0xFF00 0000 or 0xFF00 0001, or 0xFF00 0002 or 0xFF00 0003. To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891,

0x326, 0x547, write `CSI2_DBG_H` = 0x0123 4567, followed by `CSI2_DBG_H` = 0x89abcdef, and `CSI2_DBG_H` = 0x7654 3210.

## 8.2.5.5 ISS CSI2 Register Manual

### 8.2.5.5.1 ISS CSI2 Instance Summary

Table 8-153 summarizes the CSI2 instance.

**Table 8-153. ISS CSI2 Instance Summary**

Module Name	L3 Base Address	Size

RESERVED																BURST_SIZE_EXPAND	VP_CLK_EN	RESERVED	NON_POSTED_WRITE	RESERVED	VP_ONLY_EN	STREAMING_32_BIT	VP_OUT_CTRL	DBG_EN	BURST_SIZE	ENDIANNESS	FRAME	ECC_EN	RESERVED	IF_EN																

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Reserved	R	0x0000
16	BURST_SIZE_EXPAND	Sets the DMA burst size on the L3 interconnect. 0x0: Use the burst size defined in the BURST_SIZE register 0x1: Allow generation of 16x64-bit bursts	RW	0
15	VP_CLK_EN	VP clock enable. 0x0: The VP clock is disabled. 0x1: The VP clock is enabled.	RW	0
14	RESERVED	Read returns reset value	RW	0
13	NON_POSTED_WRITE	Not posted writes 0x0: Disable 0x1: Enable	RW	0
12	RESERVED		R	0
11	VP_ONLY_EN	VP only enable. 0x0: The VP is enabled and the OCP master port is enabled. 0x1: The VP is enabled and the OCP master port is disabled.	RW	0
10	STREAMING_32_BIT	Indicates if 64-bit or 32-bit streaming burst is used. Valid only if <a href="#">CSI2_CTRL.STREAMING</a> =1 0x0: 64-bit streaming burst is used; byte enable pattern is 0xFF 0x1: 32-bit streaming burst is used; byte enable pattern is 0x0F	RW	0
9:8	VP_OUT_CTRL	VP_PCLK control. Sets the VP_PCLK as a function of the ISS interconnect interface clock (OCPCLK). 0x0: No division: VP_PCLK = OCPCLK. 0x1: Division by 2: VP_PCLK = OCPCLK / 2. 0x3: Division by 4: VP_PCLK = OCPCLK / 4. 0x2: Division by 3: VP_PCLK = OCPCLK / 3. Example scenarios: - Low VP_PCLK, Memory -> VP: Same as typical memory -> VP, but VP_PCLK = OCPCLK/2 - Typical sensor -> VP: Autoidle enabled, FCLK at optimal rate, sensor provides DPCM compressed RAW12 data at 650 Mbps. Image timings VP_PCLK = (OCPCLK/2) and <a href="#">CCP2_CTRL[31:15] FRACDIV</a> = 0xD000 2600 active pixels/line, 128 blanking pixels, no vertical blanking. (This scenario corresponds to the OTF operation at maximum CCP2 speed.)	RW	0x0
7	DBG_EN	Enables the debug mode. 0x0: Disable 0x1: Enable	RW	0
6:5	BURST_SIZE	Sets the DMA burst size on the L3 interconnect. 0x0: 1x64 OCP writes 0x1: 2x64 OCP writes 0x3: 8x64 OCP writes 0x2: 4x64 OCP writes	RW	0x0
4	ENDIANNESS	Select endianness for YUV4:2:2 8 bit and YUV4:2:0 legacy formats. 0x0: Use native MIPI CSI2 endianness: Little endian for all formats except for YUV4:2:2 8b and YUV4:2:0 Legacy which a big endian. 0x1: Store all pixel formats little endian.	RW	0

Bits	Field Name	Description	Type	Reset
3	FRAME	Set the modality in which IF_EN works.  0x0: If IF_EN = 0 the interface is disabled immediately. 0x1: If IF_EN = 1 the interface is disabled after all FEC sync code have been received for the active contexts.	RW	0
2	ECC_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids).  0x0: Disabled 0x1: Enabled	RW	0
1	RESERVED	Read returns reset value	RW	0
0	IF_EN	Enables the physical interface to the module.  0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled when each context has received the FEC sync code.  0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, that is, the CSI2_CTX_CTRL.PING_PONG bits are reset to 0 as well.	RW	0

Bits	Field Name	Description	Type	Reset
31	BYTESWAP	Allows swapping bytes two by two in the payload data. It does not affect: - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0x0: Disabled 0x1: Enabled	RW	0
30	GENERIC	Enables the generic mode. 0x0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 0x1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.	RW	0
29	RESERVED		R	0x0
28	HSCALE	Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. 0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
27:24	TRANSCODE	<p>Enables image transcoding. When this features is enabled:</p> <ul style="list-style-type: none"> <li>- the data format from the camera is defined by the FORMAT register</li> <li>- the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register</li> </ul> <p>0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data</p> <p>0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data</p> <p>0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data</p> <p>0x0: Feature disabled.</p> <p>0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data</p> <p>0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data</p> <p>0x9: Outputs uncompressed RAW14 data.</p> <p>0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data</p> <p>0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data</p> <p>0x3: Outputs A-Law compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data.</p>	RW	0x0
23:16	FEC_NUMBER	<p>Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory (must be used only in interlace mode, otherwise set to 1).</p>	RW	0x01
15:8	COUNT	<p>Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to 0.</p> <p>Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit field COUNT_UNLOCK shall be written in addition to COUNT bit field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value.</p> <p>0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire</p>	RW	0x00
7	EOF_EN	<p>Indicates if the end of frame signal shall be asserted at the end of the line.</p> <p>Read 0x1: The end of frame signal is asserted at the end of each frame.</p> <p>Read 0x0: The end of frame signal is not asserted at the end of each frame.</p>	RW	0

Bits	Field Name	Description	Type	Reset
6	EOL_EN	Indicates if the end of line signal shall be asserted at the end of the line.  Read 0x1: The end of line signal is asserted at the end of each frame.  Read 0x0: The end of line signal is not asserted at the end of each frame.	RW	0
5	CS_EN	Enables the checksum check for the received payload (long packet only).  0x0: Disabled 0x1: Enabled	RW	0
4	COUNT_UNLOCK	Unlock writes to the COUNT bit field.  Write 0x0: COUNT bit field is locked. Writes have no effect  Write 0x1: COUNT bit field is unlocked. Writes are possible.	W	0
3	PING_PONG	Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame.  This bit field toggles after every FEC_NUMBER FEC sync code received for the current context.  Read 0x1: PONG buffer Read 0x0: PING buffer	R	1
2	VP_FORCE	Forces sending of the data to both VPORT and OCP. Only applies to formats that existing in two versions: - One sending data to OCP port only - One sending data to VPORT only (tagged with the +VP extension)  The format version sending data only to OCP should be chosen.  0x0: Disabled 0x1: Enabled	RW	0
1	LINE_MODULO	Line modulo configuration  0x0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ.  0x1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)	RW	0
0	CTX_EN	Enables the context  0x0: Disabled 0x1: Enabled	RW	0

## 8.2.6 ISS TCTRL

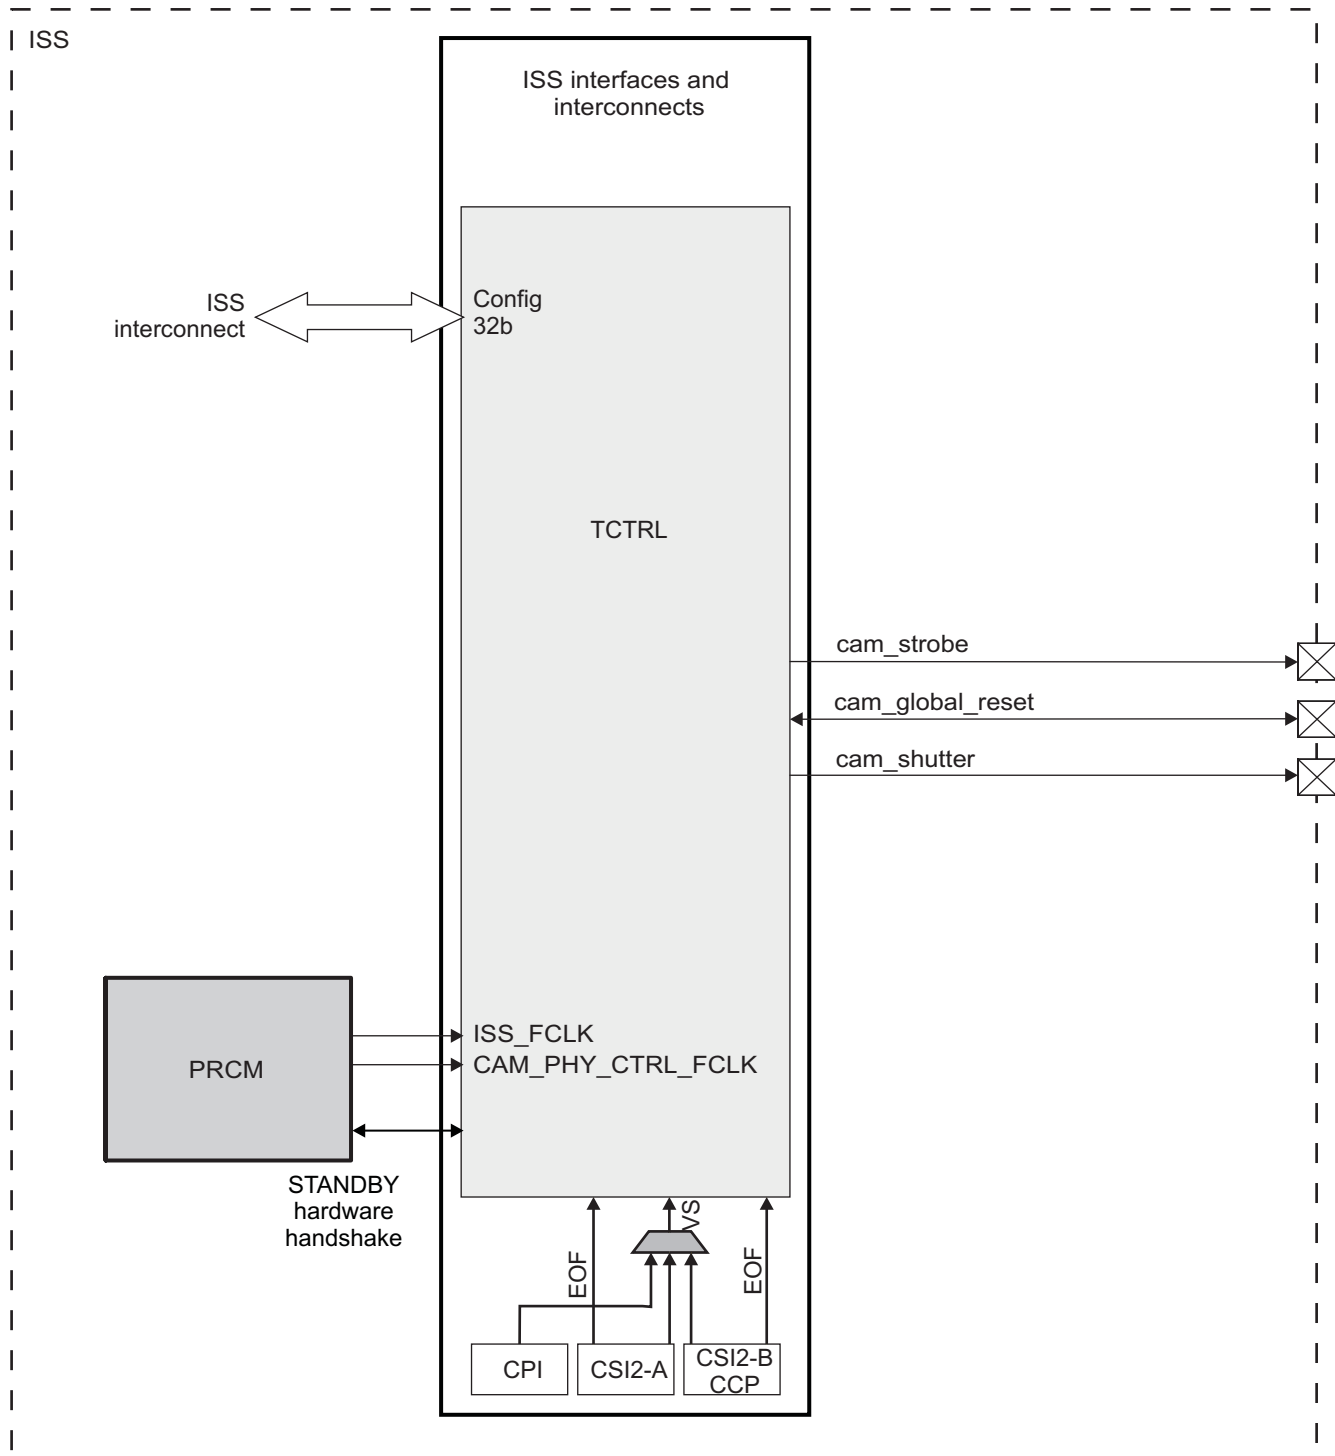

### 8.2.6.1 ISS TCTRL Environment

There are no particular environment attributes. See [Section 8.2.2](#), *ISS Interfaces Environment*.

### 8.2.6.2 ISS TCTRL Integration

[Figure 8-77](#) shows the integration of the TCTRL.

Figure 8-77. ISS TCTRL Integration

camss-355

For information about the power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

### 8.2.6.3 ISS TCTRL Functional Description

#### 8.2.6.3.1 ISS TCTRL Features

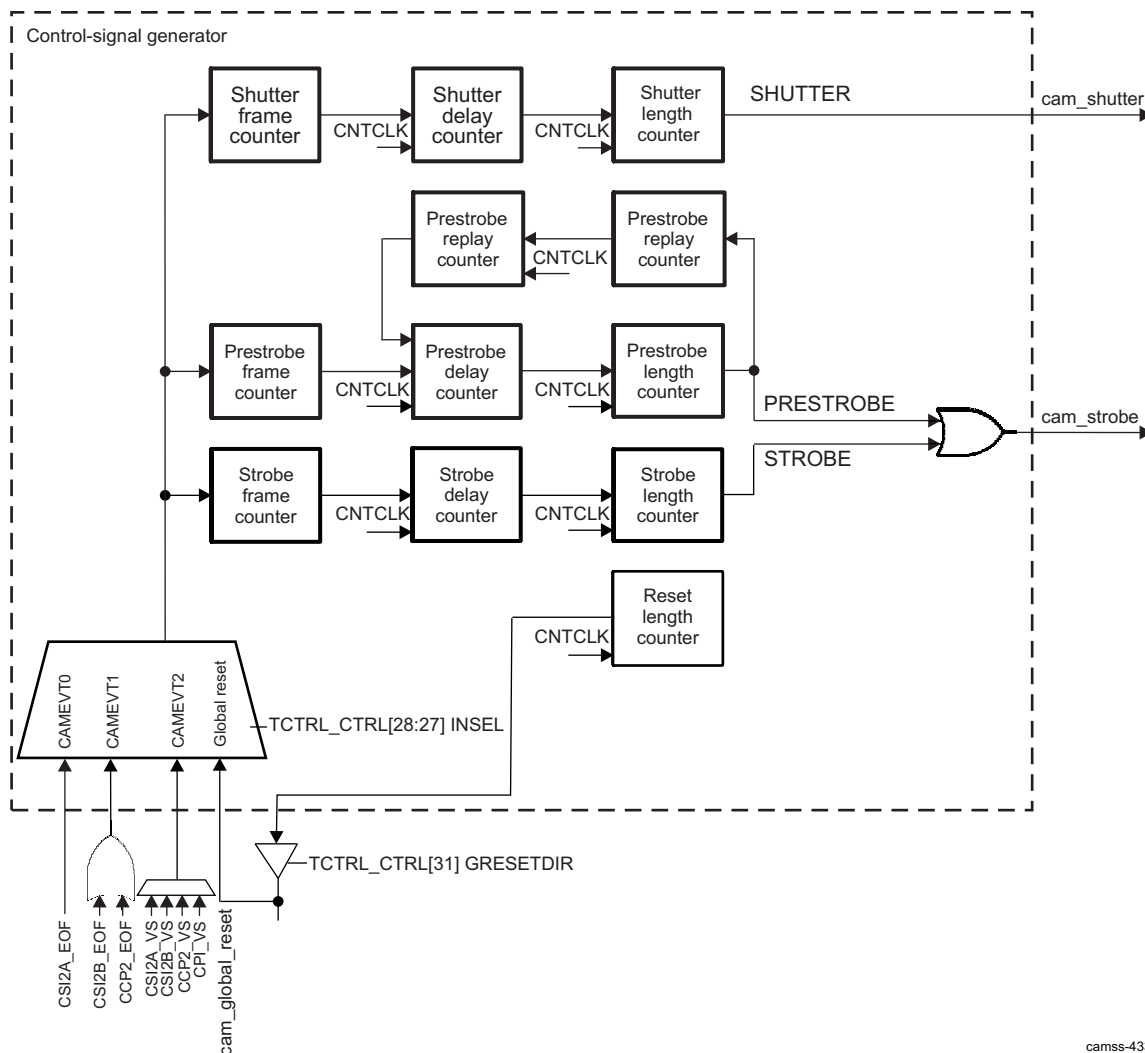

The TCTRL generates the control signals (cam\_strobe and cam\_shutter) for the flash prestrobe, flash strobe, and mechanical shutters.

The TCTRL includes a timing generator and a control-signal generator.

#### 8.2.6.3.2 ISS TCTRL Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam\_strobe and cam\_shutter. Figure 8-78 shows the principle of control-signal generation.

**Figure 8-78. TCTRL Control-Signal Generation**

camss-433

The control-signal generator gathers precise timings for the cam\_strobe and cam\_shutter signals, to assert and deassert the signals at known times. The timing control-signal generator can be synchronized on the vertical synchronization signal coming from the CSI2-A, CSI2-B, CCP2, Parallel interface (CPI), or on an externally generated cam\_global\_reset signal.

A multiplexer which of the CSI2-A, CSI2-B, CCP2, or Parallel interfaces drives control-signal generation. This multiplexer can also select the externally generated cam\_global\_reset signal as the trigger event. The TCTRL\_CTRL[31] GRESETDIR bit defines the direction of cam\_global\_reset.

- The externally generated cam\_global\_reset is used as a trigger when TCTRL\_CTRL[31] GRESETDIR

= 0 and **TCTRL\_CTRL**[28:27] INSEL = 3.

- The internally generated `cam_global_reset` is used as a trigger when **TCTRL\_CTRL**[31] GRESETDIR = 1 and **TCTRL\_CTRL**[28:27] INSEL = 3.

The `cam_global_reset` signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on internally generated `cam_global_reset`. The multiplexer controls whether control-signal generation must be triggered by the internal or external `cam_global_reset`.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the functional clock. The clock divider is programmable. [Table 8-202](#) lists the possible frequencies as a function of the divisor values.

**Table 8-202. ISS TCTRL Control-Signal Generator: CNTCLK Frequencies**

Divisor Value <b>TCTRL_CTRL</b> [18:10] DIVC	CNTCLK Clock	CNTCLK Precision (ns)
0 (default)	Clock gated. No clock.	N/A
1	200 MHz	5
2	100 MHz	10
3	66.667 MHz	15
4	50 MHz	20
...	...	...
510	0.392 MHz	2550
511	0.391 MHz	2555

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received.
  - A new frame is detected by the TCTRL module when CAMEVTx is received.
  - The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass the frame counters.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the length of control-signal assertion. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

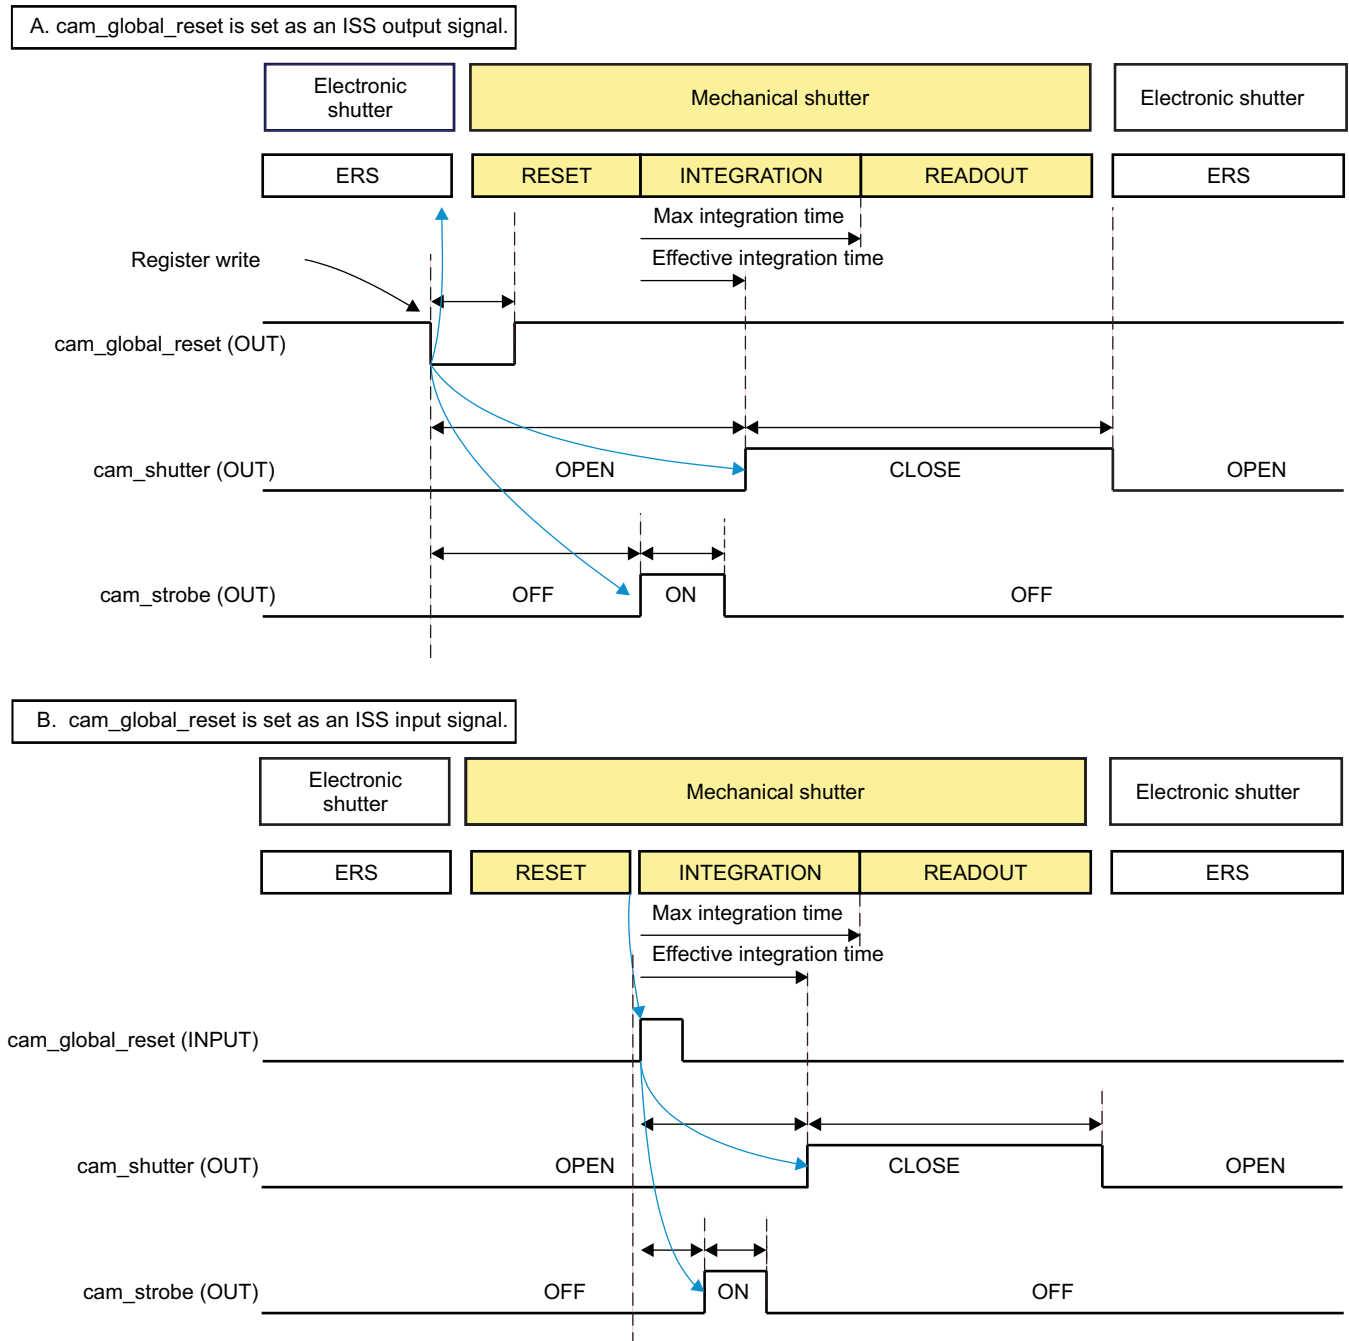

The polarity of the following signals can be individually selected:

- **TCTRL\_CTRL**[26] STRBPSTRBPOL for the prestrobe and strobe signals
- **TCTRL\_CTRL**[24] SHUTPOL for the shutter signal
- **TCTRL\_CTRL**[30] GRESETPOL for `cam_global_reset`

Software can trigger the generation of `cam_global_reset` to the camera module. The length of signal-activation is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (the **TCTRL\_CTRL**[29] GRESETEN bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of `cam_global_reset` can be selected (the **TCTRL\_CTRL**[30] GRESETPOL bit).

[Figure 8-79](#) shows the use of `cam_global_reset` set as an input or output signal. `cam_global_reset` is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle.

**Figure 8-79. ISS TCTRL Use of cam\_global\_reset With Global Reset Release Camera Modules**

camss-434

There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (cam\_global\_reset, cam\_shutter, and cam\_strobe) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

- Mechanical shutter mechanism:
  - Reset: All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
  - Integration: The light received by the sensor is transformed into electrical charges that are stored inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is

defined by the time between reset release and shutter close.

- Readout: The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.
- Electronic rolling shutter (ERS) mechanism:
  - Each line of the sensor is reset separately and read after a fixed amount of time. Exposure time is defined by the time between reset and read.

#### 8.2.6.4 ISS TCTRL Programming Model

The following settings must be done before enabling the TCTRL.

##### 8.2.6.4.1 ISS TCTRL Camera-Control Signal Generator

Two configurations apply:

- First configuration: The control signals are based on the vertical synchronization information coming from the camera module or from externally generated `cam_global_reset`.
- Second configuration: The control signals are based on internally generated `cam_global_reset`.

##### 8.2.6.4.1.1 ISS TCTRL Vertical Sync-Based Control-Signal Generation or Externally Generated `cam_global_reset`

To enable control-signal generation in the first configuration, follow the procedure listed in [Table 8-203](#).

**Table 8-203. ISS TCTRL Enabling the Control-Signal Generation in First Configuration**

Step	Bit Field	Value
Select the input that triggers the control signals. The trigger signal can come from the CSI2-A, CSI2-B/CCP2 interface, Parallel interface (CPI) or the externally generated <code>cam_global_reset</code> signal.	<a href="#">TCTRL_CTRL[28:27]</a> INSEL	0x0: CSI2A 0x1: CSI2B or CCP2 0x2: VS signal 0x3: Global reset
Set the global reset as input signal. Writes to the <a href="#">TCTRL_CTRL[29]</a> GRESETEN bit do not trigger the CAM_STROBE and CAM_SHUTTER signals and do not generate the CAM_GLOBAL_RESET signal.	<a href="#">TCTRL_CTRL[31]</a> GRESETDIR	0x0
The following bits are cleared automatically to 0 after the signal assertion:	<ul style="list-style-type: none"> <li>• <a href="#">TCTRL_CTRL[21]</a> SHUTEN</li> <li>• <a href="#">TCTRL_CTRL[22]</a> PSTRBEN</li> <li>• <a href="#">TCTRL_CTRL[23]</a> STRBEN</li> </ul>	
Set the polarity of the SHUTTER, STROBE/PRESTROBE, and <code>cam_global_reset</code> signals.	<ul style="list-style-type: none"> <li>• <a href="#">TCTRL_CTRL[24]</a> SHUTPOL</li> <li>• <a href="#">TCTRL_CTRL[26]</a> STRBPSTRBPOL</li> <li>• <a href="#">TCTRL_CTRL[30]</a> GRESETPOL</li> </ul>	
Set the clock divisor value, which generates the CNTCLK clock. The clock is set by CNTCLK = ISS_FCLK/ <a href="#">TCTRL_CTRL[18:10]</a> DIVC.	<a href="#">TCTRL_CTRL[18:10]</a> DIVC	0x0: Disable CNTCLK 0 to 511: Divider
Set the frame counters.	<ul style="list-style-type: none"> <li>• <a href="#">TCTRL_FRAME[5:0]</a> SHUT</li> <li>• <a href="#">TCTRL_FRAME[11:6]</a> PSTRB</li> <li>• <a href="#">TCTRL_FRAME[17:12]</a> STRB</li> </ul>	0: TCTRL does not delay any frame in input. 1 to 63
Set the delay counters.	<ul style="list-style-type: none"> <li>• <a href="#">TCTRL_SHUT_DELAY</a></li> <li>• <a href="#">TCTRL_PSTRB_DELAY</a></li> <li>• <a href="#">TCTRL_STRB_DELAY</a></li> </ul>	The possible values are 0 to $2^{25} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 511/200$ MHz = 85.73157376 s ( <a href="#">TCTRL_CTRL[18:10]</a> DIVC = 511).

**Table 8-203. ISS TCTRL Enabling the Control-Signal Generation in First Configuration (continued)**

Step	Bit Field	Value
Set the signal durations.	<ul style="list-style-type: none"> <li>TCTRL_SHUT_LENGTH</li> <li>TCTRL_PSTRB_LENGTH</li> <li>TCTRL_STRB_LENGTH</li> </ul>	The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 200 MHz input clock is $(2^{24} - 1) \times 511/200 \text{ MHz} = 42.865784325 \text{ s}$ (TCTRL_CTRL.DIVC = 511).
Enable the SHUTTER signal.	TCTRL_CTRL[21] SHUTEN	0x1
Enable the PRESTROBE signal.	TCTRL_CTRL[22] PSTRBEN	0x1
Enable the STROBE signal.	TCTRL_CTRL[23] STRBEN	0x1

#### 8.2.6.4.1.2 ISS TCTRL Internally Generated cam\_global\_reset-Based Control-Signal Generation

To enable control-signal generation in the second configuration, follow the procedure listed in [Table 8-204](#).

**Table 8-204. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration**

Step	Bit Field	Value
Select the input to global reset, to loop back the internally generated GLOBAL_RESET. Vertical synchronization events do not trigger the CAM_STROBE and CAM_SHUTTER signals.	TCTRL_CTRL[28:27] INSEL	0x3: Global reset
Set the global reset as output signal.	TCTRL_CTRL[31] GRESETDIR	0x1
The following bits are cleared automatically to 0 after the signal assertion:	<ul style="list-style-type: none"> <li>TCTRL_CTRL[21] SHUTEN</li> <li>TCTRL_CTRL[22] PSTRBEN</li> <li>TCTRL_CTRL[23] STRBEN</li> <li>TCTRL_CTRL[29] GRESETEN</li> </ul>	0x0
Set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam_global_reset signals.	<ul style="list-style-type: none"> <li>TCTRL_CTRL[24] SHUTPOL</li> <li>TCTRL_CTRL[26] STRBPSTRBPOL</li> <li>TCTRL_CTRL[30] GRESETPOL</li> </ul>	
Set the clock divisor value, which generates the CNTCLK clock. The clock is set by CNTCLK = ISS_FCLK/TCTRL_CTRL[18:10] DIVC.	TCTRL_CTRL[18:10] DIVC	0x0: Disable CNTCLK 0 to 511: Divider
Set the frame counters.	<ul style="list-style-type: none"> <li>TCTRL_FRAME[5:0] SHUT</li> <li>TCTRL_FRAME[11:6] PSTRB</li> <li>TCTRL_FRAME[17:12] STRB</li> </ul>	0: TCTRL does not delay any frame in input. 1 to 63
Set the delay counters.	<ul style="list-style-type: none"> <li>TCTRL_SHUT_DELAY</li> <li>TCTRL_PSTRB_DELAY</li> <li>TCTRL_STRB_DELAY</li> </ul>	The possible values are 0 to $2^{25} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 511/200 \text{ MHz} = 85.73157376 \text{ s}$ (TCTRL_CTRL[18:10] DIVC = 511).

**Table 8-204. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration (continued)**

Step	Bit Field	Value
Set the signal durations.	<ul style="list-style-type: none"> <li>TCTRL_SHUT_LENGTH</li> <li>TCTRL_PSTRB_LENGTH</li> <li>TCTRL_STRB_LENGTH</li> </ul>	The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 200 MHz input clock is $(2^{24} - 1) \times 511 / 200 \text{ MHz} = 42.865784325 \text{ s}$ (TCTRL_CTRL.DIVC = 511).
Set the cam_global_reset assertion time.	TCTRL_GRESET_LENGTH	The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 200 MHz input clock is $(2^{24} - 1) \times 511 / 200 \text{ MHz} = 42.865784325 \text{ s}$ (TCTRL_CTRL.DIVC = 511).
Enable the SHUTTER signal.	TCTRL_CTRL[21] SHUTEN	0x1
Enable the PRESTROBE signal.	TCTRL_CTRL[22] PSTRBEN	0x1
Enable the STROBE signal.	TCTRL_CTRL[23] STRBEN	0x1
Enable the cam_global_reset control-signal generation.	TCTRL_CTRL[29] GRESETEN	0x1

**NOTE:** Setting the following bits to 1 simultaneously leads to unpredictable behavior:

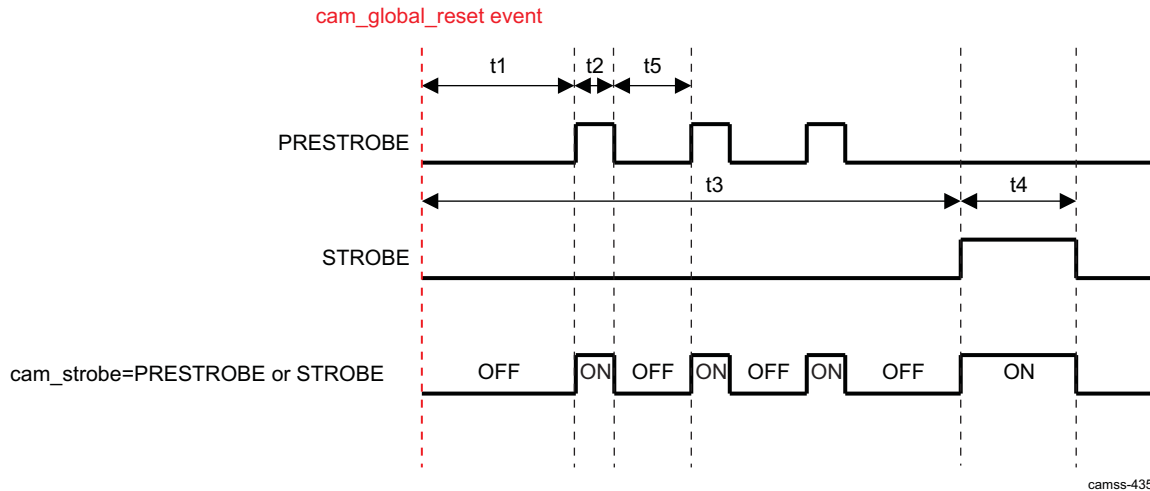

- TCTRL\_CTRL[21] SHUTEN
- TCTRL\_CTRL[22] PSTRBEN
- TCTRL\_CTRL[23] STRBEN
- TCTRL\_CTRL [29] GRESETEN

The following bits must be set before TCTRL\_CTRL[29] GRESETEN is enabled:

- TCTRL\_CTRL[21] SHUTEN
- TCTRL\_CTRL[22] PSTRBEN
- TCTRL\_CTRL[23] STRBEN

#### 8.2.6.4.1.3 ISS TCTRL STROBE and PRESTROBE Signal Generation for Red-Eye Removal

The STROBE and PRESTROBE signal generation enables a strobe flash for red-eye removal. The process is shown in [Figure 8-80](#). The dotted line corresponds to known timings from which the delay counters start decreasing: cam\_global\_reset event.

**Figure 8-80. cam\_strobe Signal-Generation for Red-Eye Removal**

- t1: Set by the [TCTRL\\_PSTRB\\_DELAY](#) register
- t2: Set by the [TCTRL\\_PSTRB\\_LENGTH](#) register
- t5: Set by the [TCTRL\\_PSTRB\\_REPLAY\[24:0\]](#) DELAY bit field. The number of times the pulse is repeated is controlled by the [TCTRL\\_PSTRB\\_REPLAY\[31:25\]](#) COUNTER bit field.  
In the previous example, [TCTRL\\_PSTRB\\_REPLAY\[31:25\]](#) COUNTER = 2.
  - The possible delay values are 0 to  $2^{25} - 1$  cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is  $(2^{25} - 1) \times 511/200$  MHz = 85.73157376 s ([TCTRL\\_CTRL\[18:11\]](#) DIVC = 511).
  - The possible count values are 0 to 127 additional pulses.
- t3: Set by the [TCTRL\\_STRB\\_DELAY](#) register
- t4: Set by the [TCTRL\\_STRB\\_LENGTH](#) register

## 8.2.6.5 ISS TCTRL Register Manual

### 8.2.6.5.1 ISS TCTRL Instance Summary

[Table 8-205](#) summarizes the TCTRL instance.

**Table 8-205. ISS TCTRL Instance Summary**

Module Name	L3 Base Address	Size
<a href="#">ISS_TCTRL</a>	0x5200 0400	256 bytes

### 8.2.6.5.2 ISS TCTRL Registers

#### 8.2.6.5.2.1 ISS TCTRL Register Summary

[Table 8-206](#) summarizes the TCTRL registers.

**Table 8-206. ISS TCTRL Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	ISS_TCTRL Base Address
<a href="#">TCTRL_REVISION</a>	R	32	0x0000 0000	0x5200 0400

<b>Address Offset</b>	0x0000 0030	<b>Instance</b>	ISS_TCTRL
<b>Physical Address</b>	0x5200 0430		
<b>Description</b>	TIMING CONTROL - CONTROL REGISTER		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GRESETDIR	GRESETPOL	GRESETEN	INSEL	STRBPSTRBPOL	RESERVED	SHUTPOL	STRBEN	PSTRBEN	SHUTEN	RESERVED	DIVC						RESERVED														

Bits	Field Name	Description	Type	Reset
31	GRESETDIR	Sets the direction of the GLOBAL_RESET signal. 0x0: INPUT – GLOBAL_RESET is an input to the TIMING CONTROL module. GLOBAL_RESET is externally generated. 0x1: OUTPUT – GLOBAL_RESET is an output of the TIMING CONTROL module. GLOBAL_RESET is internally generated. If GRESETEN is set to 1, the internally generated GLOBAL_RESET will trigger the generation of the PRESTROBE, STROBE and SHUTTER signals. The frame counters are ignored.	RW	0
30	GRESETPOL	Sets the polarity of the global reset signal: CAM_GLOBAL_RESET. It applies whatever the direction of the GLOBAL_RESET signal: input or output. 0x0: active high 0x1: active low	RW	0

Bits	Field Name	Description	Type	Reset
29	GRESETEN	Triggers the generation of the CAM_GLOBAL_RESET signal. The signal is asserted immediately. If enabled, the CAM_GLOBAL_RESET signal will be asserted for <a href="#">TCTRL_GRESET_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. The polarity of the GLOBAL_RESET signal is set with <a href="#">TCTRL_CTRL.GRESETPOL</a> . Enabling this bit triggers the generation of the CAM_SHUTTER and CAM_STROBE signals (if previously enabled). The frame counters shall be set to 0 when this bit is set to 1 and GRESETDIR is set a OUTPUT.	RW	0
28:27	INSEL	Sets the mode that will trigger the SHUTTER, PRESTROBE and STROBE signals. 0x0: Synchronization event from camera 0 0x1: Synchronization event from camera 1 0x3: GRESET – The CAM_GLOBAL_RESET input signal will trigger the SHUTTER, PRESTROBE and STROBE signals. In this mode, there are no frame counters. The delay counters start decrementing as soon as the GLOBAL_RESET signal is asserted. The polarity of the GLOBAL_RESET signal is set with <a href="#">TCTRL_CTRL.GRESETPOL</a> . 0x2: Synchronization event from camera 2 (serial interfaces muxed with the camera Parallel interface (CPI))	RW	0x0
26	STRBPSTRBPOL	Sets the polarity of the strobe and prestrobe signals. 0x0: Active high 0x1: Active low	RW	0
25	RESERVED		R	0
24	SHUTPOL	Sets the polarity of the mechanical shutter signal: CAM_SHUTTER 0x0: Active high 0x1: Active low	RW	0
23	STRBEN	Flash strobe signal enable. If enabled, the STROBE signal will be asserted after <a href="#">TCTRL_FRAME.STRB</a> frames have been received and a delay of <a href="#">TCTRL_STRB_DELAY</a> cycles have passed. The STROBE signal is asserted for <a href="#">TCTRL_STRB_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal shall not be disabled by software.	RW	0
22	PSTRBEN	Flash prestrobe signal enable. If enabled, the PRESTROBE signal will be asserted after <a href="#">TCTRL_FRAME.PSTRB</a> frames have been received and a delay of <a href="#">TCTRL_PSTRB_DELAY</a> cycles have passed. The PRESTROBE signal is asserted for <a href="#">TCTRL_PSTRB_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal shall not be disabled by software.	RW	0
21	SHUTEN	Mechanical shutter signal enable. If enabled, the SHUTTER signal will be asserted after <a href="#">TCTRL_FRAME.SHUT</a> frames have been received and a delay of <a href="#">TCTRL_SHUT_DELAY</a> cycles have passed. The SHUTTER signal is asserted for <a href="#">TCTRL_SHUT_LENGTH</a> cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal shall not be disabled by software.	RW	0
20:19	RESERVED		R	0x0

Bits	Field Name	Description	Type	Reset
18:10	DIVC	Sets the clock divisor value for the CNTCLK clock generation based on the CLK input clock. CNTCLK is an internal clock used by the TIMING CTRL module counters. Usually, CNTCLK = CLK / DIVC, except for some particular values shown hereafter. 0x0: No clock. CNTCLK is gated.	RW	0x000
9:0	RESERVED		R	0x000

**Table 8-229. TCTRL\_PSTRB\_REPLAY**

<b>Address Offset</b>	0x0000 0034	<b>Instance</b>	ISS_TCTRL
<b>Physical Address</b>	0x5200 0434		
<b>Description</b>	TIMING CONTROL - PRESTROBE REPLAY REGISTER This register is used by the TIMING CTRL module to generate the prestrobe signal.		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNTER								DELAY																							

Bits	Field Name	Description	Type	Reset
31:25	COUNTER	Sets the number of PRESTROBE pulses after the original pulse. If this bit is set to 0, the PRESTROBE signal behavior is only controlled by <a href="#">TCTRL_FRAME.STRB</a> , <a href="#">TCTRL_PSTRB_DELAY</a> , and <a href="#">TCTRL_PSTRB_LENGTH</a> . If <a href="#">TCTRL_PSTRB_LENGTH</a> =0, there is no replay. This bit is useful when one wants to enable red-eye removal.	RW	0x00
24:0	DELAY	Sets the delay for the PRESTROBE signal reassertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the <a href="#">TCTRL_CTRL.DIVC</a> bit field. The possible values are 0 to $2^{25}-1$ cycles. If <a href="#">TCTRL_PSTRB_LENGTH</a> =0, there is no replay. This bit field shall not be set to 0 if the COUNTER is set to a value different of 0. This bit is useful when one wants to enable red-eye removal.	RW	0x0000000

## **8.2.7 ISS BTE**

### **8.2.7.1 ISS BTE Environment**

There are no particular environment attributes (see [Section 8.2.2, ISS Interfaces Environment](#)).

8.2.7.2 ISS BTE Integration

Figure 8-81. ISS BTE Integration

camss-318

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

### 8.2.7.2.1 ISS BTE PRCM Interface

#### 8.2.7.2.1.1 ISS BTE Power Management

##### 8.2.7.2.1.1.1 ISS BTE PRCM Handshake

The BTE supports the IDLE protocol to flush outstanding transactions. When an IDLE request is received, the BTE:

- Completes ongoing requests on OCPI (request, data and response phases) and stalls the port (SCmdAccept = 0)
- Flushes all contexts (same behavior than when the [BTE\\_CONTEXT\\_CTRL\\_i\[2\]](#) FLUSH bit is set by software) when the [BTE\\_CONTEXT\\_CTRL\\_i\[11\]](#) AUTOFLUSH bit is set. Otherwise, no context flushing is triggered by an IDLE request.
- Completes ongoing requests on OCPO (request, data and response phases)
- Acknowledges the IDLE request.

### 8.2.7.3 ISS BTE Functional Description

#### 8.2.7.3.1 ISS BTE Features

The BTE increases access efficiency of raster initiators to tiled SDRAM. In fact, the TILER expects 2D-bursts corresponding to a row or column of subtiles for maximal efficiency. For more information about SDRAM and TILER, see [Section 15.2, Dynamic Memory Manager](#).

The BTE is connected between one or multiple raster initiators. It can translate reads and writes. For reads, BTE prefetches sufficient data from tiled memory to translate raster requests. For writes, BTE buffers raster requests until it has sufficient data to generate requests to tiled memory. The features of the BTE are:

- Interfaces:
  - 32-bit-wide configuration interface (OCPC)
  - 128-bit-wide slave data port (OCPI)
  - 128-bit-wide master data port (OCPO)
- Incrementing to 2D burst translation for read and writes:
  - Four contexts. A context is a virtual frame buffer attached to a data flow requiring translation.
  - One-shot and continuous mode
- Local memories for temporal storage:
  - Cannot use external memories for temporal data storage
- Transparent for accesses that do not require translation. Requests are forwarded from OCPI to OCPO without modification.
- Local buffer

#### 8.2.7.3.2 ISS BTE Functional Description Details

The main tasks and capabilities of the BTE are:

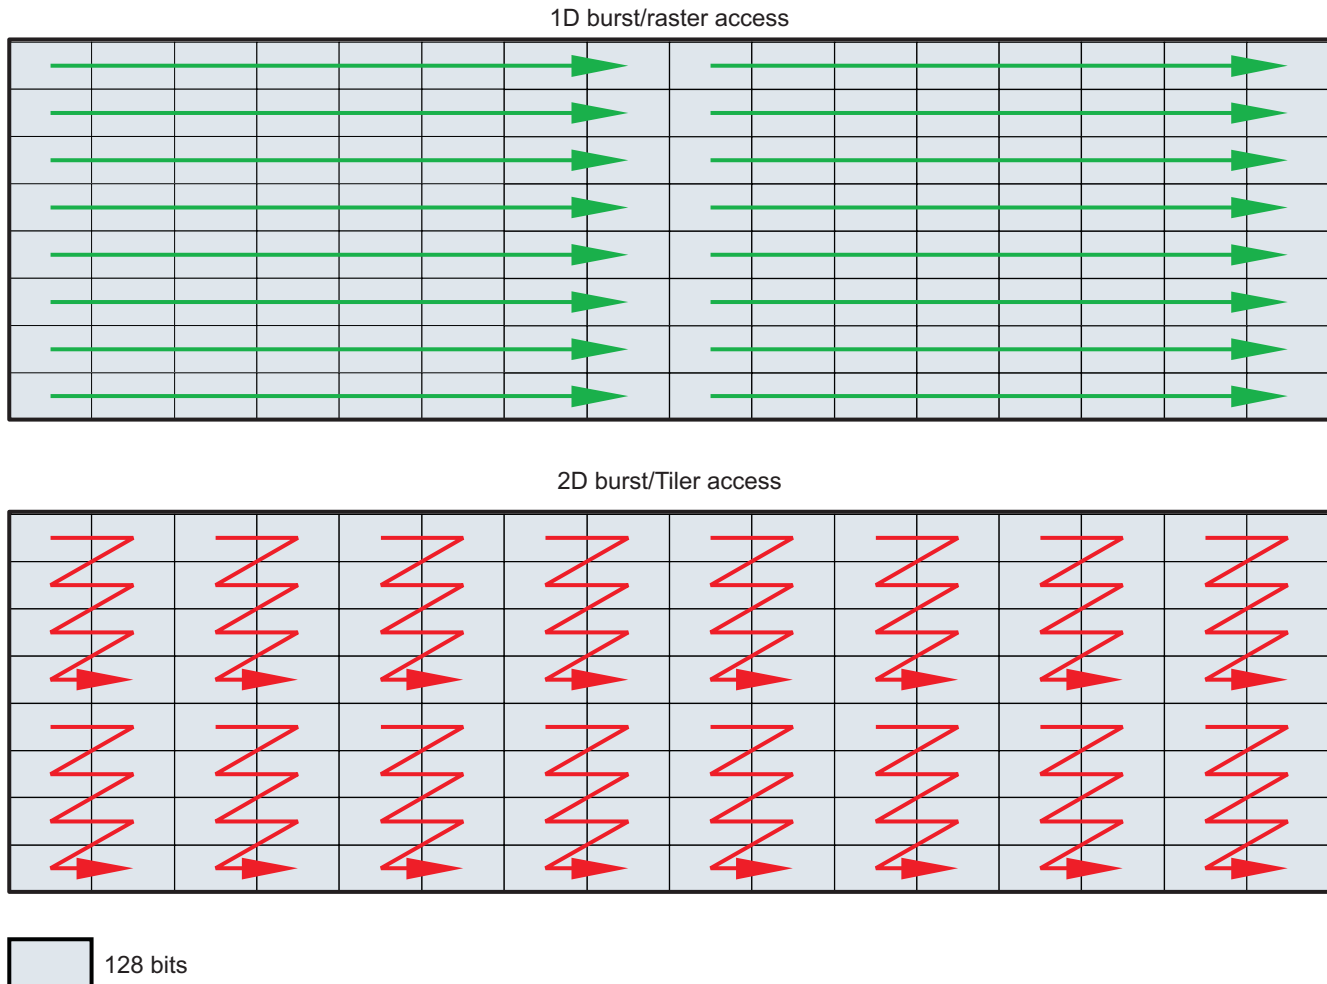

- Forward OCP transactions that do not need translation.
- For OCP writes requiring translation:
  - Store data received from OCPI to local buffers.
  - Read data from local buffers and send it to OCPO.
- For OCP read requiring translation:
  - Store data received from OCPO to local buffers.
  - Read data from local buffers and send it to OCPI.
- BTE DMA capability

**8.2.7.3.2.1 ISS BTE Burst Translation Principle**

The BTE receives raster accesses from the OCPI port and generates TILER accesses on OCPO.

The BTE keeps track of the amount of data written into the local memories. For translated writes, 2D bursts are sent to OCPO when there is sufficient data in the local memory to generate TILER accesses. For translated reads, 2D burst are generated to fill the local memory with data that is returned when raster accesses are received on OCPI. [Figure 8-82](#) shows the BTE burst translation principle.

**Figure 8-82. ISS BTE Burst Translation Principle**

camss-320

In the following sections, three address spaces are described:

- Virtual: Corresponds to the translated address region on OCPI. Accesses performed to this address space are translated by the BTE. It can be seen as a 64KB x 8 k lines frame buffer. Locations in this space are expressed as byte addresses for OCP compliance. However, the access granularity is 128-bit (4 LSBs expected to be zeros). For more information about this space, see [Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping](#).
- Physical: Corresponds to the addresses used to access the physical buffer of the BTE. The physical space is addressed in 128-bit-wide words. However, this document refers to byte addresses to preserve homogeneity.
- Tiler: Corresponds to addresses used by translated accesses. Locations in this space are expressed as byte addresses for OCP compliance. However, the access granularity is 128-bit (4 LSBs expected to be zeros). For more information about this space, see [Section 8.2.7.3.2.5, ISS BTE TILER Space Accesses: 2D Burst Generation](#).

### 8.2.7.3.2.2 ISS BTE Virtual Address Space and Context Mapping

The location of the virtual space in the address map of OCPI is set by the `BTE_CTRL[11:8]` BASE bit field. It always occupies 64KB × 8k lines = 512MB. Software must map a virtual space into an unused region (a region, for example, that the ISS top level cannot access).

The virtual space is decomposed into contexts. A context corresponds to a 2D region in the virtual space that requires burst translation. It can also be seen as a virtual frame buffer.

Accesses to different contexts can be interleaved at OCP transaction level. OCP transactions spanning multiple contexts are not allowed.

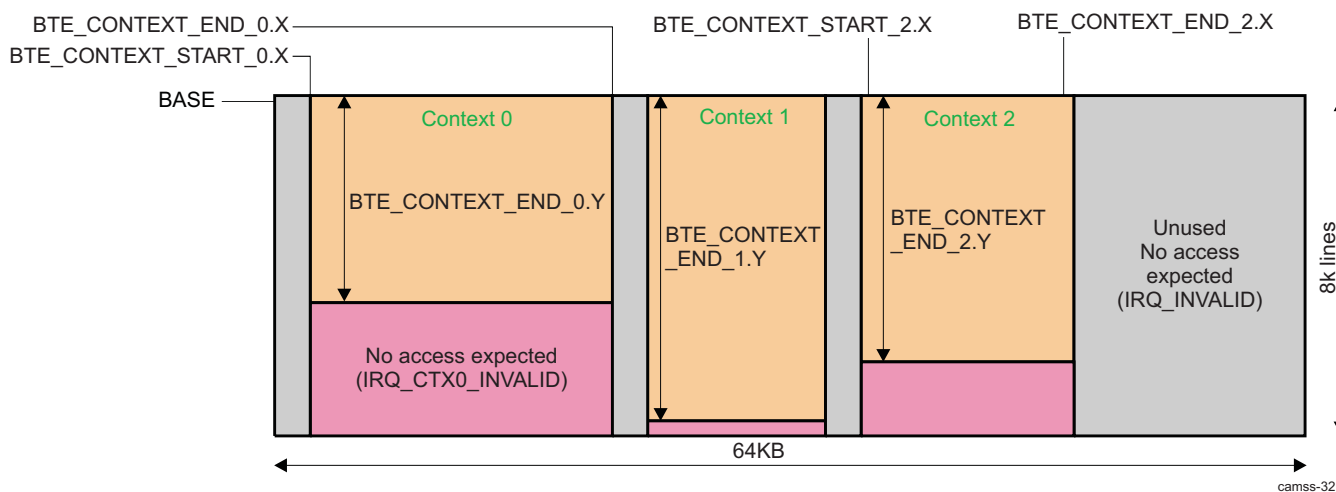

When the BTE receives an access from the OCPI port, it performs the following checks:

- If the access address is not between BASE 512MB and (BASE + 1) 512MB 1, it is handled as a transparent: request and data phases are simply forwarded to the OCPO without modification.
- If the access falls into the translated region:
  - If the access is a 2D burst, an `IRQ_INVALID` event is generated.
  - If the access does not map to an active context, an `IRQ_INVALID` event is generated. The BTE ignores bits [28:16] for this test.
  - Otherwise, context mapping is performed (see [Figure 8-83](#)).

Invalid requests are not forwarded to the OCPO.

Software must ensure that contexts do not overlap. The BTE hardware does not check for this condition. Wrong setup is likely to lead to corrupted data.

**Figure 8-83. ISS BTE Context Mapping**

The BTE internally keeps track of every context where the next access is expected. It internally maintains a 2D pointer, referred to as  $(SX_i, SY_i)$  in the remainder of this document. The expected byte address for an access into context  $x$  is:

$$\text{ADDR} = \text{BTE\_CTRL}[11:8] \text{ BASE } 512\text{MB} + \text{SX}_i \text{ 16 bytes} + \text{SY}_i \text{ 64KB}$$

If an access to an unexpected location in a given context is received from OCPI, the BTE generates an `IRQ_CTXx_INVALID` event. The BTE provides a valid response on OCPI but does not store any data into the internal buffer. Subsequent accesses are handled normally: in other words, the BTE does not enter any specific error mode. When this happens, typically an initiator configuration is not aligned with the BTE context configuration.

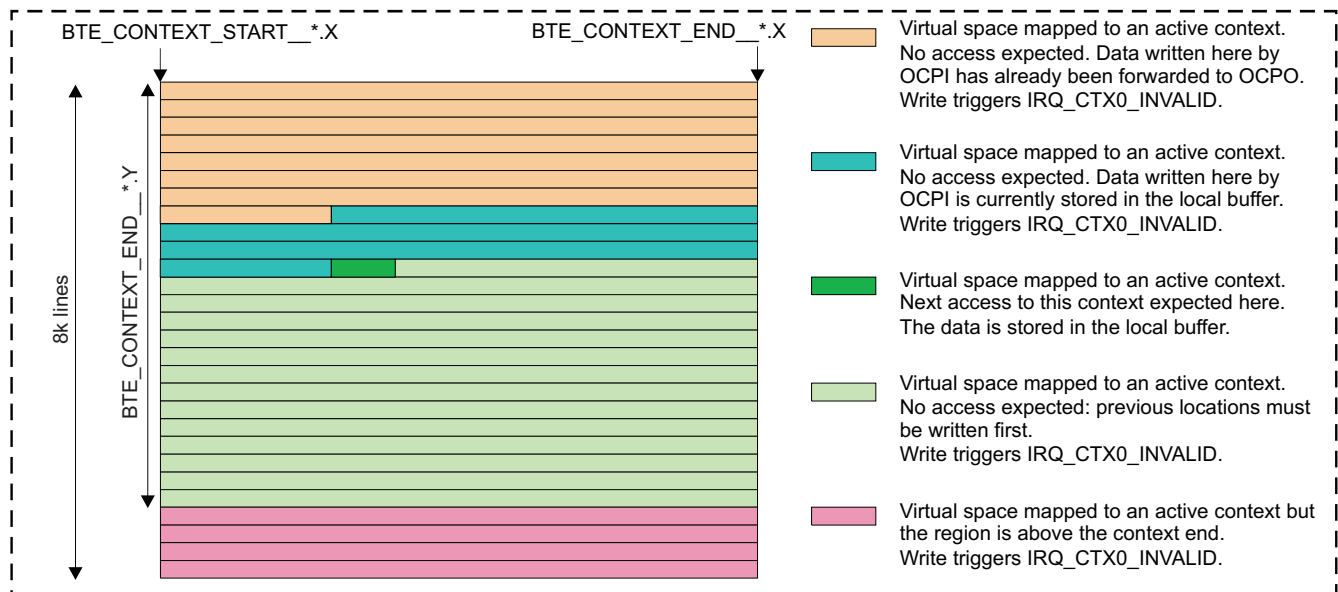

The (SX<sub>i</sub>, SY<sub>i</sub>) pointer of a context is updated on every access to this context. It is reset to SX<sub>i</sub> = BTE\_CONTEXT\_START<sub>i</sub>[15:7] X and SY<sub>x</sub> = 0 when a context is enabled. SX<sub>i</sub> is incremented by 1 for every received 16-byte word, except when it equals BTE\_CONTEXT\_END<sub>i</sub>[15:4] X. In that case it is reset to BTE\_CONTEXT\_START<sub>i</sub>[15:7] X and SY<sub>i</sub> is incremented. SY<sub>i</sub> is reset when it reaches the bottom-right corner of the context.

Therefore, the BTE can only translate raster accesses:

- Image data must be provided line by line, starting from the top-left corner of the context.
- A line stride of 64KB is expected.
- The maximum supported image height is 8k lines.

Figure 8-84 is an example of an active context. There is only one location in an active context where an access from OCPI is expected (green). Accesses to any other location trigger an IRQ\_CTXx\_INVALID event. Reads to contexts in write mode (BTE\_CONTEXT\_CTRL<sub>i</sub>[7:6] MODE = 0) or writes to contexts in read mode (BTE\_CONTEXT\_CTRL<sub>i</sub>[7:6] MODE = 1) trigger an IRQ\_CTXx\_INVALID event. When an access to an expected location is received but the burst length exceeds the context end, an IRQ\_CTXx\_INVALID event is triggered.

Figure 8-84. ISS BTE Expected Access Locations in the Virtual Space

camss-322

Some alignment constraints are summarized as follows and are shown in Figure 8-85. They apply only to translated accesses.

- The context start addresses are aligned on 16-byte boundaries.
- The context width is aligned on 16-byte boundaries.
- The OCPI initiator must not use BYTEEN to qualify subwords in the middle of lines. The BTE interprets each BYTEEN as 0xFFFF. Access of partial words triggers an IRQ\_CTXx\_INVALID error.
- The line length sent by the initiator can be 1-byte aligned. The initiator can use BYTEEN to qualify valid data for the last access of the line. The BTE treats those accesses as full 16-byte writes and writes 0 data into its local buffers to complete the access. Those 0s are forwarded to OCPO when burst translation is performed. Software must ensure this data is discarded when the buffer is read back.
- The BTE does not impose any specific constraint on vertical alignment on the TILER tile and subtile grids. However, it is strongly recommended to configure the burst generation in such a way the requests performed to the TILER do not cross tile or subtile boundaries. For more information, see Section 8.2.7.3.2.5, ISS BTE TILER Space Accesses: 2D Burst Generation.
- The BTE accepts only one outstanding transaction per OCP tag on the OCPI port. When an initiator

tries to generate an OCP request on a tag ID that is already used (no response has been returned on OCPI), the OCPI port is stalled.

- The amount of memory allocated for each context must be a multiple of 512 bytes. Software must leave  $\text{mod}(\text{BTE\_CONTEXT\_END}_i - \text{BTE\_CONTEXT\_START}_i + 1, 8)$  unused locations between the end of the context and the start of the next one. No accesses to this space from OCPI are allowed, but the BTE can use it to store data.
- While programming a BTE context, the BTE context End X value of all contexts must be less than  $\text{MEMORY}/64$  in 128-bit address (equals  $\text{MEMORY}/4$  in byte address)

**NOTE:** The generic BTE MEMORY size can be found by reading the `BTE_HL_HWINFO[18:0]` MEMORY bit field.

- While reading from a BTE-translated location, the CCP2 read burst size must be greater than or equal to ( $\geq$ ) 16 bytes (128 bits) for correct operation. Bus width translation is performed in the ISS. Therefore, 64-bit accesses lead to 128-bit accesses with `BYTEEN = 0x00FF`. On the BTE side, `BYTEEN` is always processed as `0xFFFF`; thus, access to a BTE-translated 128-bit location is not correct if software uses 64-bit access.

Figure 8-85 shows the BTE context alignment constraints.

**Figure 8-85. ISS BTE Context Alignment Constraints**

camss-323

### 8.2.7.3.2.3 ISS BTE TILER Context Configuration Example

Global configuration and context configuration must be done before traffic from the master can be enabled.

This section provides a configuration example used to write YUV4:2:0 data into a 90-degree rotated buffer ( $S = 1, Y = 1, X = 0$ ). The YUV frame is made up of two objects: Y data (8 bits) and UV data (16 bits).

The BTE provides data orientation and format information to the TILER using a 33-bit address. It can be controlled by software using the `BTE_CONTEXT_BASE_i` and `BTE_CONTEXT_CTRL_i[12]` ADDR32 bits. ADDR32 must be set to 1. Bits [31:27] of the address control the accessed view format. Table 8-233 is an example of a BTE TILER context configuration.

Figure 8-86 shows BTE TILER mode addressing in 90- or 270-degree orientation.

**Table 8-233. ISS BTE TILER Context Configuration Example**

32	31	30	29	28	27	26 ... 4	3 ... 0
T	Orientation			Mode		Virtual Address	
1	S	/Y	/X	M1	M0	A26 ... A4	0

For the example described here, the following settings are used:

90-degree view, 8-bit data            ADDR[32:27] = 0b1 110 00  
 90-degree view, 16-bit data        ADDR[32:27] = 0b1 110 01

Software must also configure the `BTE_CONTEXT_CTRL_i[9:8]` GRID bit field to match the view and format set by the base address:

90-degree view, 8-bit data            GRID = 1    Stride = 8k  
 90-degree view, 16-bit data        GRID = 1    Stride = 8k

**Figure 8-86. ISS BTE TILER Mode Addressing in 90- or 270-Degree Orientation**

camss-701

Bits [26:0] of the `BTE_CONTEXT_BASE_i` register are used to address a pixel in the virtual space of TILER. It must point to the top-left corner of the 2D object.

Software must also configure the other context register before it can start it by setting the `BTE_CONTEXT_CTRL_i[0]` START bit.

#### 8.2.7.3.2.4 ISS BTE Local Memory Management

##### 8.2.7.3.2.4.1 ISS BTE Introduction

The amount of data buffered is defined by the `BTE_CONTEXT_CTRL_i[29:16]` TRIGGER bit field. In write mode, translated 2D writes to OCPO are issued when the buffer fill level is greater than or equal to the value of the `BTE_CONTEXT_CTRL_i[29:16]` TRIGGER bit field. In read mode, translated 2D reads are sent to OCPO when the buffer level is less than the value of the `BTE_CONTEXT_CTRL_i[29:16]` TRIGGER bit field.

##### 8.2.7.3.2.4.2 ISS BTE Buffer Flushing

###### 8.2.7.3.2.4.2.1 ISS BTE One-Shot Mode

One-shot mode is enabled by setting the `BTE_CONTEXT_CTRL_i[10]` ONESHOT bit.

During normal operation, a data transfer from local memory to the TILER is automatically triggered when sufficient data is available in the buffer.

Three lines of data remain in the buffer once the OCPI initiator stops sending data into the context.

The BTE supports two ways to flush data remaining in the buffer:

- The last data (bottom-right corner) in a context is written. The last data is defined by the `BTE_CONTEXT_END_i[15:4]` X and `BTE_CONTEXT_END_i[28:16]` Y bit fields.
- Software writes the `BTE_CONTEXT_CTRL_i[2]` FLUSH bit. This is typically done when the context has been stopped before the full frame has been written.

An autoflush mode controls automatic context flushing when an IDLE request is received. It can be activated by setting the `BTE_CONTEXT_CTRL_i[11]` AUTOFLUSH bit to 1.

During a context flush, all remaining data in the buffer are written to the TILER.

Buffer flushing has lower priority than burst translation active contexts or forwarding transparent accesses. This prevents performance degradation.

If software wants to abort context operation at a random location, it must disable the context.

#### 8.2.7.3.2.4.2 ISS BTE Continuous Mode

When continuous mode is selected (the `BTE_CONTEXT_CTRL_i[10]` ONESHOT bit set to 0), reception of frame *n* pushes the data remaining from frame 1 out of the memory to OCPO. This mode is particularly useful when vertical blanking periods are too short to perform a buffer flush at the end of the frame. Also, it avoids creating traffic peaks due to buffer flushing.

The frame height must be a multiple of eight lines and the `BTE_CONTEXT_CTRL_i[14:13]` INITSY bit field must be 0x0 in continuous mode.

#### 8.2.7.3.2.4.3 ISS BTE Buffer Prefetch

The buffer must be prefilled before read requests requiring translation can be accepted. Buffer prefetch starts with the top-left corner of the frame when a context is enabled by setting the `BTE_CONTEXT_CTRL_i[0]` START bit. When enough lines have been prefetched, an `IRQ_CTXx_DONE` event is triggered to inform software that the context is ready to perform request translation. Typically, software enables the data flow requiring translation in response to this event. Context ready for transaction and last transaction can be controlled by `BTE_CONTEXT_START` and `BTE_CONTEXT_END`, respectively.

When a read request requiring translation is received while prefetch is ongoing, an `IRQ_CTXx_ERR` event is triggered. It informs software that the read traffic was enabled too early. The BTE returns 0s to OCPI for the failing request (it does not hold the response until real data is available).

After prefetch completion, when a request requiring translation is received but the required data is missing (the BTE is waiting for a response from OCPO), the BTE delays the response on OCPI until the missing data is received on OCPI.

This behavior avoids stalling the OCPI port for too long (that is, a prefetch of up to 3.25 lines of data). However, it avoids getting errors because of slow OCPI responses.

#### 8.2.7.3.2.4.4 ISS BTE Bandwidth Limiter

Translated and transparent traffic has higher priority than prefetch and flushing traffic. However, overall system bandwidth is limited. Requesting too much bandwidth for prefetch and flushing traffic may increase latencies for higher priority traffic. That could affect higher priority traffic.

Software can limit the speed of prefetching and buffer flushing by using the `BTE_CTRL[31:22]` `BW_LIMITER` bit field. Typically, this register is used to avoid the buffer prefetch and flush traffic using all the available system bandwidth. This register does not slow down the translated or transparent traffic.

The example in [Figure 8-87](#) assumes:

- 200-MHz functional clock
- 800 Mbps of transparent traffic = one 8 × 128-bit burst every 32 cycles

Without the bandwidth limiter, prefetch and flush traffic may use up to  $3.2 - 0.8 = 2.4$  Gbps. Using `BTE_CTRL[31:22]` `BW_LIMITER` = 24 ensures that at a maximum one flush/prefetch request is issued every 32 cycles. A prefetch/flush request may be delayed by higher priority traffic of OCP port stalls. To avoid excessive traffic slowdown, the BTE tries to catch up by requesting the next flush/prefetch transaction earlier.

**Figure 8-87. BTE Bandwidth Limiter Example**

camss-332

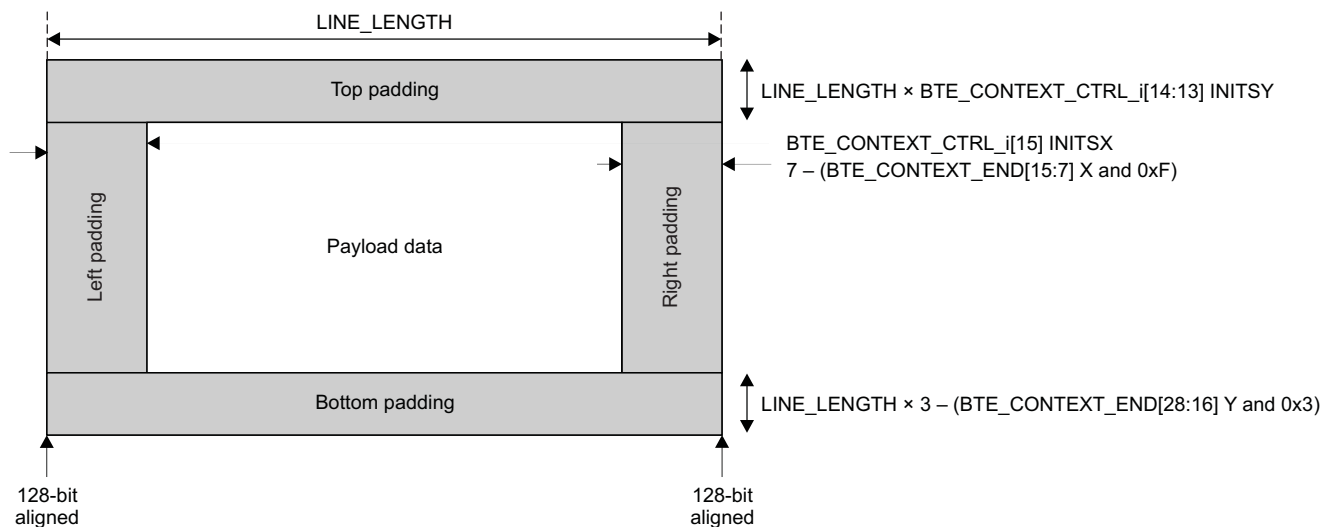

8.2.7.3.2.5 ISS BTE TILER Space Accesses: 2D Burst Generation

8.2.7.3.2.5.1 ISS BTE Buffer Fill Level

The BTE maintains an internal counter to keep track of the buffer fill level. This internal counter is used to detect when a translated OCP request is sent to the OCPO port. The counter also accounts for padding data. Figure 8-88 shows the BTE buffer fill-level padding.

Figure 8-88. ISS BTE Buffer Fill-Level Padding

camss-333

In BTE context, the preferred parameter to be used is 128-bit word as unit. The `BTE_CONTEXT_START_i` and `BTE_CONTEXT_END_i` registers are usually written as byte-aligned; however, the `BTE_CONTEXT_START_i.X` and `BTE_CONTEXT_END_i.X` bit fields are more readily understood (nominally) as (128 bytes = 8 x 128 bits = 8 words).

The (lower half) `BTE_CONTEXT_END_i` register must be written as byte-aligned, but the `BTE_CONTEXT_END_i.X` bit field is understood (nominally) as (128 bits = 1 word).

The BTE TRIGGER is based on word size (128 bits), but the related register (upper half) `BTE_BTE_CONTEXT_CTRL_i` register is not byte-aligned; it is word-aligned (128-bits).

$$LINE\_LENGTH = ((BTE\_CONTEXT\_END\_i[15:4] X) - BTE\_CONTEXT\_START\_i[15:7] X) \& 0xFF8 + 8$$

**NOTE:** `LINE_LENGTH` is measured as a 128-bit word and can be used directly for TRIGGER calculation ( $3 * LINE\_LENGTH + x$ )

Example 1: 64 x 15 pixels line = 64 x 15 Nb bytes in a line  
 (Nb bytes in a line – 16(128-bit word)) 4 = 0x3B  
`LINE_LENGTH` = (0x3B & 0xFF8) + 8 = 0x40  
`TRIGGER` = 0x40 \* 3 + 2 = 0xC2

Example 2: 64 x 11 pixel line = 64 x 11 Nb bytes in a line  
 (Nb bytes in a line – 16(128-bit word)) 4 = 0x2B  
`LINE_LENGTH` = (0x2B & 0xFF8) + 8 = 0x30  
`TRIGGER` = 0x30 \* 3 + 2 = 0x92

Figure 8-88 is a visual representation of the following explanation about how read or write events are triggered determined by the internal buffer size.

When context is started, the buffer fill level is initialized to  $\text{LINE\_LENGTH} \times \text{BTE\_CONTEXT\_CTRL\_i}[14:13] \text{ INITSY} + \text{BTE\_CONTEXT\_CTRL\_i}[15] \text{ INITSX}$  (see the previous equation for the  $\text{LINE\_LENGTH}$  calculation). If the BTE reads or writes, the level of the internal buffer is incremented or decremented, respectively, by the burst size. Here, only full 16-byte accesses are performed. Other OCP BYTEEN patterns are forced to 0xFF.

The  $\text{BTE\_CONTEXT\_CTRL\_i}[29:16] \text{ TRIGGER}$  bit field triggers a buffer level read or write even. In write mode, if flushing, the data level is greater than 0; if not flushing, the BTE translates to OCPO when the level is greater than or equal to the value set by the register. If the level is smaller than the  $\text{BTE\_CONTEXT\_CTRL\_i}[29:16] \text{ TRIGGER}$  software setup, then the BTE reads data.

#### 8.2.7.3.2.5.2 ISS BTE OCP Request Generation

Except on borders:

- TILER bursts are 32 bytes  $\times$  4 lines of data blocks.
- Bursts are aligned on subtile boundaries.

The BTE maintains an internal 2D pointer ( $\text{DX}_i, \text{DY}_i$ ) that corresponds to the top-left corner of the next access to be issued to the TILER. It is initialized to (0, 0) when a context is enabled or wraps around. It is updated each time an access to the TILER is performed.

[Table 8-234](#) lists all supported TILER formats and views.

**Table 8-234. ISS BTE Supported TILER Formats and Views**

Modes	View			Description	OFST	Subtile Grid		1KB Tile Grid		X		Y		GRID	Subtile Aligned		Tile Aligned	
	S	/Y	/X			X	Y	X	Y	LSB	MSB	LSB	MSB		X	Y	X	Y
8-bit	0	0	0	0-degree view	16384	4	4	32	32	0	13	14	26	0	[1:0]	[15:14]	[4:0]	[18:14]
	0	0	1	0-degree view with vertical mirror														
	0	1	0	0-degree view with horizontal mirror														
	0	1	1	180-degree view														
	1	0	0	90-degree view with vertical mirror	8192	4	4	32	32	0	12	13	26	1	[1:0]	[14:13]	[4:0]	[17:13]
	1	0	1	270-degree view														
	1	1	0	90-degree view														
	1	1	1	90-degree view with horizontal mirror														
16-bit	0	0	0	0-degree view	32768	8	2	64	16	0	14	15	26	2	[2:0]	[15]	[5:0]	[18:15]
	0	0	1	0-degree view with vertical mirror														
	0	1	0	0-degree view with horizontal mirror														
	0	1	1	180-degree view														
	1	0	0	90-degree view with vertical mirror	8192	4	4	32	32	0	12	13	26	1	[1:0]	[14:13]	[4:0]	[17:13]
	1	0	1	270-degree view														
	1	1	0	90-degree view														
	1	1	1	90-degree view with horizontal mirror														
32-bit	0	0	0	0-degree view	32768	8	2	64	16	0	14	15	26	2	[2:0]	[15]	[5:0]	[18:15]
	0	0	1	0-degree view with vertical mirror														
	0	1	0	0-degree view with horizontal mirror														
	0	1	1	180-degree view														
	1	0	0	90-degree view with vertical mirror	16384	8	2	64	16	0	13	14	26	3	[2:0]	[14]	[5:0]	[17:14]
	1	0	1	270-degree view														
	1	1	0	90-degree view														
	1	1	1	90-degree view with horizontal mirror														

The `BTE_CONTEXT_BASE_i` and `BTE_CONTEXT_CTRL_i[9:8]` GRID registers must be configured by software to choose the format and view. The format must match the data stored into the virtual space. The choice of the view depends on the desired behavior.

The GRID bit field controls the used OCP stride and OCP address generation. The OCP address is generated using the following formula:

$$\text{OCP\_ADDR} = \text{BTE\_CONTEXT\_BASE\_n} + \text{DX\_x} + \text{DY\_x} \ll \text{Y\_LSB}$$

`Y_LSB` corresponds to the Y LSB column of [Table 8-234](#).

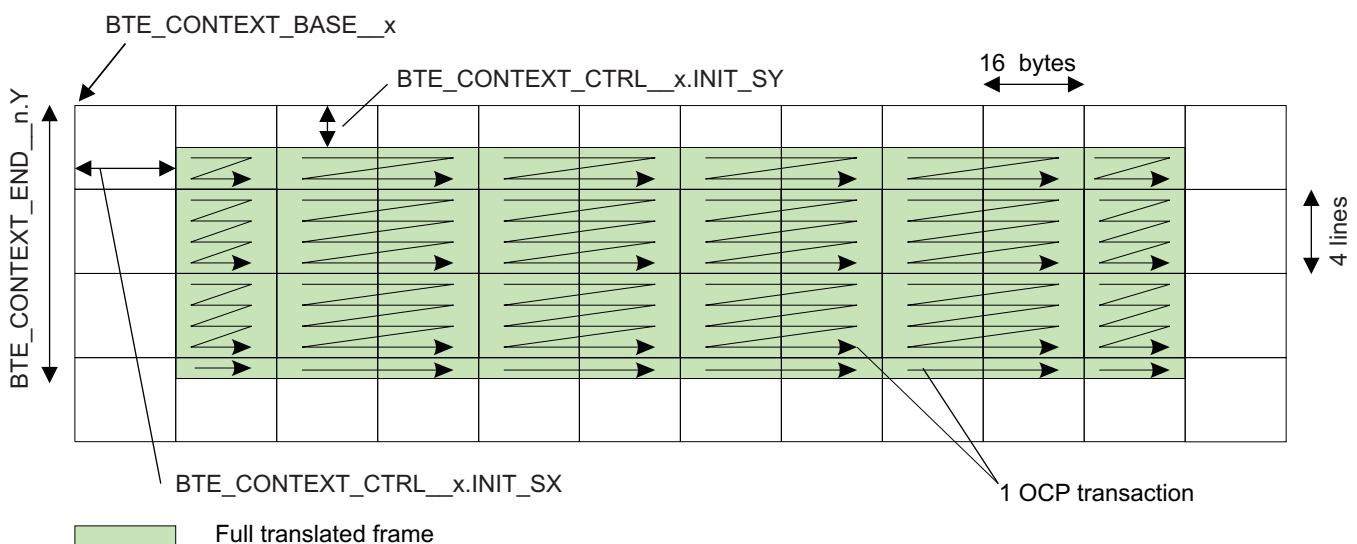

The OCP stride corresponds to the OFST column of [Table 8-234](#). The tile and subtile grid information is currently not used by hardware.

The BTE does not automatically realign 2D bursts on tile or subtile boundaries. However, software can force the  $(\text{SX}_i, \text{SY}_i)$  (see [Section 8.2.7.3.2.4](#), *ISS BTE Local Memory Management*, for the definition of  $\text{SY}_i$ ) reset value to be used. It is set through the `BTE_CONTEXT_CTRL_i[15]` `INITSX` bit and the `BTE_CONTEXT_CTRL_i[14:13]` `INITSY` bit field.

The length and height of the 2D burst is adapted by the BTE to avoid sending dummy data to the TILER.

[Figure 8-89](#) is an example of BTE 2D burst generation. The vertical start and end of the full 2D frame are not vertically aligned on the grid.

**Figure 8-89. ISS BTE 2D Burst Generation**

camss-336

### 8.2.7.3.2.6 ISS BTE Posted and Nonposted Write Support

The BTE can handle posted and nonposted writes received on OCPI. Normally, only nonposted writes should be used.

For transparent accesses, posted and nonposted writes are forwarded to OCPO. The response provided by OCPO is returned to OCPI.

For translated accesses, the response to posted and nonposted writes is provided by the BTE. It does not wait for the response of the translated request that is sent to the TILER. In other words, the BTE has no true nonposted write support for translated accesses. The BTE does not ensure that the data has effectively been written to the destination memory when it returns the response to a nonposted translated write.

True nonposted write support is ensured for transparent accesses. Only nonposted writes must be used. Select nonposted write mode through the `BTE_CTRL[5]` `POSTED` bit.

### 8.2.7.3.2.7 ISS BTE Error Reporting

Unexpected accesses are flagged using interrupts. Also, when an SResp = ERR is received on OCPO, an interrupt is triggered. If the response corresponds to a transparent access, it is forwarded to OCPI.

The BTE is not an OCP checker: It expects only valid and supported transactions from the external world.

Also, it is not intended to detect all types of software errors; few cases are detected. Those cases are described in the functional description sections.

### 8.2.7.3.2.8 ISS BTE Interrupts

All events generated by the module are merged into a single event at ISS level. This event can be enabled from ISS level by the ISS\_HL\_IRQENABLE\_SET\_i[11] BTE\_IRQ bit. [Table 8-235](#) lists the BTE interrupt events.

**Table 8-235. ISS BTE Interrupt Events**

Event	Description
IRQ_OCP_ERR	OCP error received from OCPO master port
IRQ_INVALID	An access to a location that is not mapped to any context has been performed. For more information, see <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
IRQ_CTXx_DONE	Context has been fully transferred to the TILER. This interrupt is triggered when flushing completes in one-shot mode. It is triggered once per frame in continuous mode.
IRQ_CTXx_INVALID	Unexpected address sequence or access direction (read of a context in write mode or write of a context in read mode). For more information, see <a href="#">Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping</a> .
IRQ_CTXx_ERR	Can occur only when a context is configured in read mode. This request triggers when a read request is received but insufficient data is buffered to perform the translation. For more information, see <a href="#">Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch</a> .

### 8.2.7.3.2.9 ISS BTE Debug Support

The BTE has no specific debug support.

## 8.2.7.4 ISS BTE Programming Model

### 8.2.7.4.1 ISS BTE Reset

The BTE can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the [BTE\\_HL\\_SYSCONFIG\[0\] SOFTRESET](#) bit to 1.
2. Read the [BTE\\_HL\\_SYSCONFIG\[0\] SOFTRESET](#) bit to check whether it is set to 1, which means the reset occurred.

If after five reads, the [BTE\\_HL\\_SYSCONFIG\[0\] SOFTRESET](#) bit still returns 0, assume that an error occurred during the reset stage.

Programmers must not set the [BTE\\_HL\\_SYSCONFIG\[0\] SOFTRESET](#) bit to 1 if the BTE is integrated in a subsystem; it is safer to use the software reset at subsystem level.

---

**NOTE:** A software reset does not reset the IDLE protocol signals.

---

### 8.2.7.4.2 ISS BTE Interrupts

All events are mapped to a single interrupt output, BTE\_IRQ. [Table 8-236](#) lists the procedure to configure or manage the BTE interrupts.

**Table 8-236. ISS BTE Configure/Manage Interrupts**

Step	Bit Field	Value
Each event that generates an interrupt can be individually enabled by setting the appropriate bit.	<a href="#">BTE_HL_IRQENABLE_SET</a>	
Each event that generates an interrupt can be individually disabled by setting the adequate bit.	<a href="#">BTE_HL_IRQENABLE_CLR</a>	
When an event occurs, the corresponding bit in the <a href="#">BTE_HL_IRQSTATUS_RAW</a> register is set, regardless of whether or not the event is enabled. Bits in the <a href="#">BTE_HL_IRQSTATUS</a> registers are set only when an enabled event occurs.	<a href="#">BTE_HL_IRQSTATUS_RAW</a> and <a href="#">BTE_HL_IRQSTATUS</a>	
Software can clear a pending event by setting the adequate bit in the <a href="#">BTE_HL_IRQSTATUS</a> register.	<a href="#">BTE_HL_IRQSTATUS</a>	

### 8.2.7.4.3 ISS BTE Context Configuration

Global configuration and context configuration must be done before traffic from the master can be enabled.

This section provides a configuration example used to write YUV4:2:0 data into a 90-degree rotated buffer (S = 1, Y = 1, X = 0). The YUV frame consists of two objects: Y data (8 bits) and UV data (16 bits).

The BTE provides data orientation and format information to the TILER using a 33-bit address. It can be controlled by software using the [BTE\\_CONTEXT\\_BASE\\_i](#) and [BTE\\_CONTEXT\\_CTRL\\_i\[12\]](#) ADDR32 registers.

ADDR32 must be set to 1. Bits [31:27] of the address control the accessed view and data format. [Table 8-237](#) gives the format of the TILER address. [Figure 8-90](#) shows BTE tiled mode addressing in 90- or 270-degree orientation.

**Table 8-. TILER Address Format**

32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
T	Orientation		Mode		Virtual Address																															
1	S	▷	◁	M1	M0	A26 ... A4																										0				

For the example described here, the following settings are used.

90-degree view, 8-bit data            ADDR[32:27] = 0b1 110 00

90-degree view, 16-bit data        ADDR[32:27] = 0b1 110 01

Software must also configure the [BTE\\_CONTEXT\\_CTRL\\_i\[9:8\]](#) GRID bit field to match the view and format set by the base address:

90-degree view, 8-bit data            GRID = 1    Stride = 8k

90-degree view, 16-bit data        GRID = 1    Stride = 8k

**Figure 8-90. ISS BTE Tiled Mode Addressing in 90- or 270-Degree Orientation (S = 1)**

camss-340

Bits [26:0] of the [BTE\\_CONTEXT\\_BASE\\_i](#) register are used to address a pixel in the virtual space of the TILER. It must point to the top-left corner of the 2D object.

Software must also configure the other context registers before it can start it by setting the [BTE\\_CONTEXT\\_CTRL\\_i\[0\]](#) START bit.

#### 8.2.7.4.4 ISS BTE Change Context Configuration

All contexts operate independently. Software can change the configuration of an inactive context while other contexts are active and perform request translation.

When software must change the configuration of an active context, it must follow the sequence in [Table 8-238](#).

**Table 8-238. ISS BTE Change Context Configuration**

Step	Bit Field	Value
Ensure that the initiator does not send any more data to this context until it is re-enabled.		
Disable the context. <ul style="list-style-type: none"> <li>The STOP condition is considered on a valid OCP boundary.</li> <li>It preserves the internal states so that buffer flushing can be done.</li> <li>The BTE no longer translates requests received for this context. Any transactions received for an inactive context trigger error interrupts.</li> <li>The BTE completes all outstanding transactions on OCPO.</li> </ul>	<a href="#">BTE_CONTEXT_CTRL_i[1]</a> STOP	0x1
Flush all remaining data for the context, if needed. If software simply wants to abort the transfer to recover from some error condition, flushing is not needed. The context is automatically reset when it is enabled again.	<a href="#">BTE_CONTEXT_CTRL_i[2]</a> FLUSH	0x1
Wait until the context completes pending OCP transaction and buffer flush (if enabled). It sets the <a href="#">IRQ_CTXx_DONE</a> when it becomes idle.	<a href="#">BTE_HL_IRQSTATUS</a> . <a href="#">IRQ_CTXx_DONE</a>	Read 0x0
Change the context configuration.		
Enable the context by setting the <a href="#">BTE_CONTEXT_CTRL_i[0]</a> START bit. Setting the START bit resets the internal state-machine of the context.	<a href="#">BTE_CONTEXT_CTRL_i[0]</a> START	0x1

Alternatively, software can change the context mode to one-shot and wait until the [CTXx\\_DONE\\_IRQ](#) is triggered.

---

**NOTE:** Once a context is disabled it cannot be resumed simply by writing the START bit. In fact, doing so resets the internal FSM. If data is lost in the buffer, it will be lost.

---

### 8.2.7.5 ISS BTE Register Manual

#### 8.2.7.5.1 ISS BTE Instance Summary

[Table 8-239](#) lists the BTE instance.

**Table 8-239. ISS BTE Instance Summary**

Module Name	L3 Base Address	Size
<a href="#">ISS_BTE</a>	0x5200 2000	512 bytes

### 8.2.7.5.2 ISS BTE Registers

#### 8.2.7.5.2.1 ISS BTE Register Summary

Table 8-240 summarizes the BTE registers.

**Table 8-240. ISS BTE Registers Mapping Summary**

Register Name	Type	Register Width (Bits)	Address Offset	ISS_BTE Base Address

## **8.2.8 ISS CBUFF**

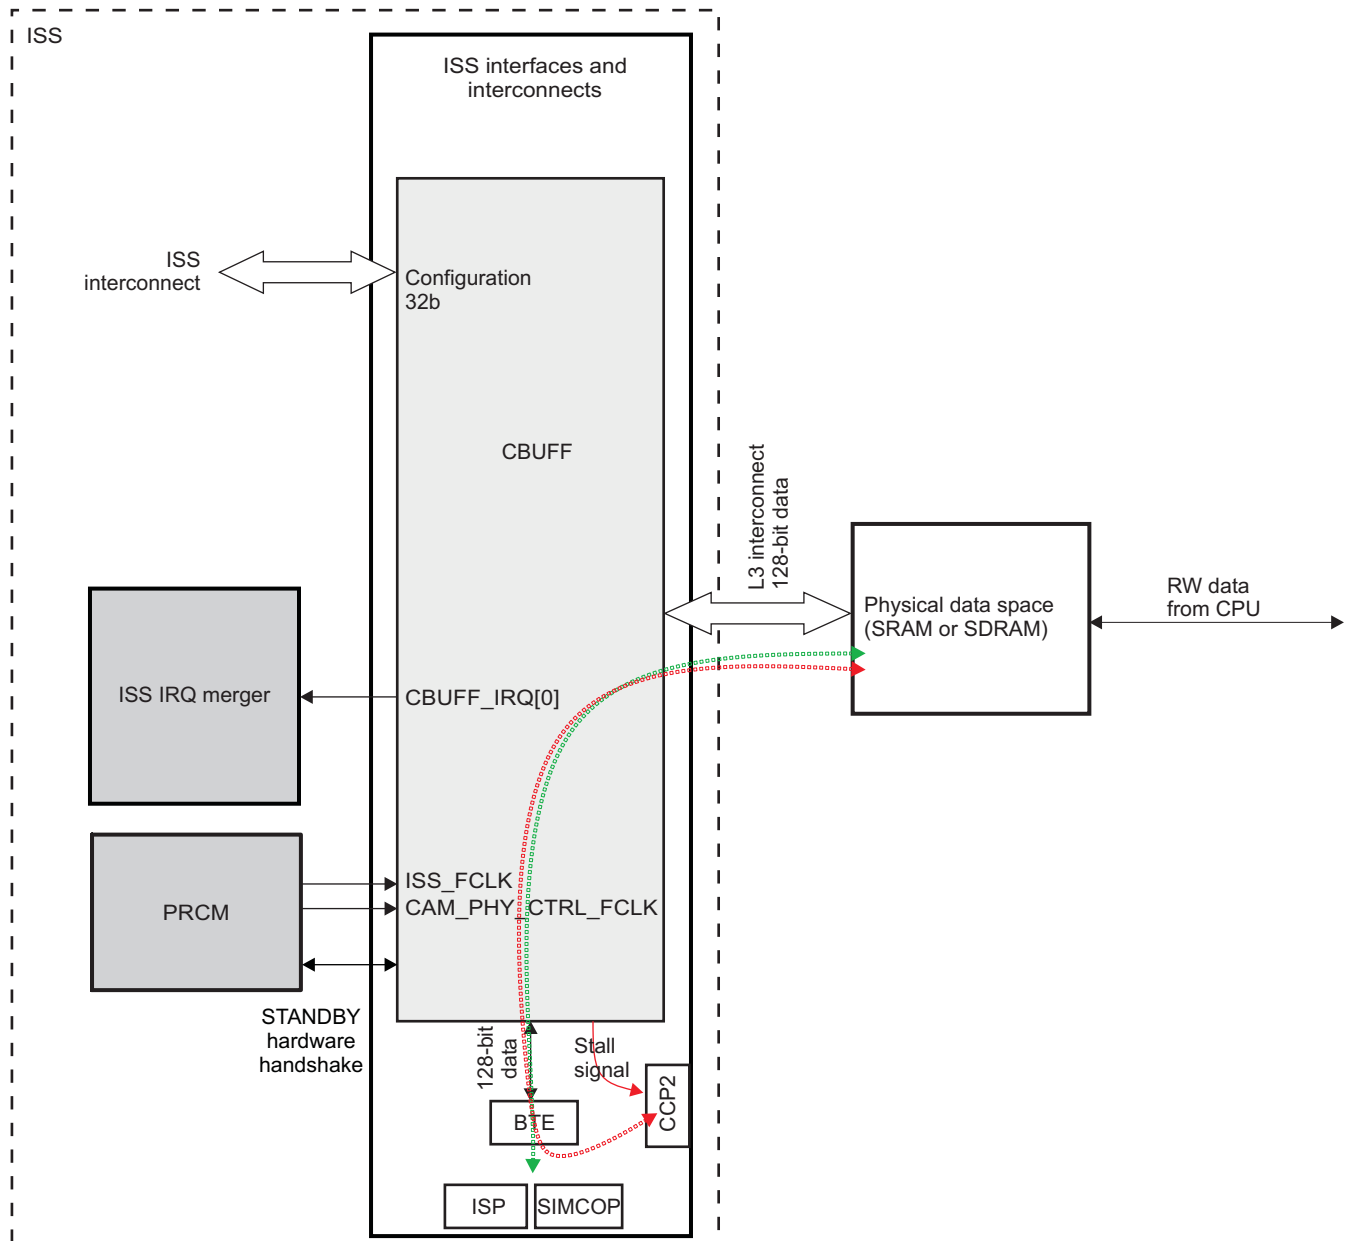

### **8.2.8.1 ISS CBUFF Environment**

There are no particular environment attributes. See [Section 8.2.2, \*ISS Interfaces Environment\*](#).

### **8.2.8.2 ISS CBUFF Integration**

[Figure 8-91](#) shows the integration of the CBUFF in the ISS. Because the CBUFF maps a virtual memory space from the physical memory, it therefore communicates with the ISS ISP and ISS interface modules for data to and from memory. This figure shows the normal data flow for further processing by the ISP and/or still-image coprocessor (SIMCOP) (in green) and the stall functionality of CBUFF (in red), which stall the data for a certain amount of time. An example of stalling is when the ISP processes the data faster than the input from CCP2 to memory. The CBUFF then must stall the data flow until a sufficient amount of data can be read from memory by the ISP.

**Figure 8-91. ISS CBUFF Integration**

RED - Stalled data flow  
 GREEN - Normal data flow

camss-679

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

### 8.2.8.2.1 ISS CBUFF PRCM Interface

#### 8.2.8.2.1.1 ISS CBUFF Reset and Idle Mechanism

A reset signal is provided by the PRCM module to the top-level ISS power and clock-management module.

For standby, when none of the ISS modules require CBUFF execution actions, ISS PM executes the standby sequence, which reaches the CBUFF. When an IDLE request arrives, the CBUFF data is drained. After all transactions are drained, the CBUFF acknowledges the IDLE request to the ISS PM/CM. The IDLE request/acknowledge steps are:

When an IDLE request is received in smart-idle mode:

1. CBUFF stops accepting any new OCP requests on a clean OCP transaction boundary.
2. Waits until the interrupt output becomes inactive (no more enabled event pending)
3. Waits until all outstanding OCP transactions are complete on OCPO and OCPI. CBUFF keeps track of issued requests, data phases, and responses for that purpose.
4. CBUFF disconnects the OCPO port.
5. CBUFF acknowledges the IDLE request.

When a wake-up request is received in smart-idle mode:

1. CBUFF connects the OCPO port.
2. Starts accepting new requests from OCPI
3. Acknowledges the functional state

Idle mode is controlled through the [CBUFF\\_HL\\_SYSCONFIG\[3:2\]](#) IDLEMODE bit field. For software reset, it is recommended to use the global ISS reset; if a reset is required, it can be set from the [CBUFF\\_HL\\_SYSCONFIG\[0\]](#) SOFTRESET bit.

### 8.2.8.2.2 ISS CBUFF Interrupts

All events generated by the module are merged into a single event at ISS level. This event can be mapped to the MPU subsystem by enabling the [ISS\\_HL\\_IRQENABLE\\_SET\\_i\[10\]](#) CBUFF\_IRQ bit. [Table 8-267](#) lists the procedure to manage CBUFF interrupts.

**Table 8-267. ISS CBUFF Interrupt Management**

Description	Bit Field	Value
Each event that generates an interrupt can be individually enabled by setting the appropriate bit.	<a href="#">CBUFF_HL_IRQENABLE_SET</a>	
Each event that generates an interrupt can be individually disabled by setting the appropriate bit.	<a href="#">CBUFF_HL_IRQENABLE_CLR</a>	
When an event occurs, the corresponding bit in the <a href="#">CBUFF_HL_IRQSTATUS_RAW</a> register is set regardless of whether or not the event is enabled. Bits in the <a href="#">CBUFF_HL_IRQSTATUS</a> registers are only set only when an enabled event occurs	<a href="#">CBUFF_HL_IRQSTATUS_RAW</a> and <a href="#">CBUFF_HL_IRQSTATUS</a>	
Software can clear a pending event by setting the appropriate bit in the <a href="#">CBUFF_HL_IRQSTATUS</a> register.	<a href="#">CBUFF_HL_IRQSTATUS</a>	

The CBUFF can generate three events per context and one global event. All events are merged into one physical interrupt line. [Table 8-268](#) describes the CBUFF-generated events.

**Table 8-268. ISS CBUFF-Generated Events**

Event	Description
IRQ_CTXx_READY	Read mode: CPU can write data to the physical window pointed by <a href="#">CBUFF_CTX_STATUS_i[3:0]</a> WB.
	Write mode: CPU can read data from the physical window pointed by <a href="#">CBUFF_CTX_STATUS_i[3:0]</a> WB.
	Read/write mode: The OCPI initiator has completed writing a physical window.
IRQ_CTXx_INVALID	Invalid access
	OCPI writes the virtual space of context i in read mode.
	OCPI reads the virtual space of context i in write mode.
	OCPI writes the virtual space of context i outside the <a href="#">CBUFF_CTX_STATUS_i[11:8]</a> WA window in write or read/write mode.

**Table 8-268. ISS CBUFF-Generated Events (continued)**

Event	Description
	OCPI reads the virtual space of context i outside the <code>CBUFF_CTX_STATUS_i[11:8]</code> WA window in read mode.
	OCPI reads the virtual space of context i outside the <code>CBUFF_CTX_STATUS_i[3:0]</code> WB window in read/write mode.
	CPU writes the DONE bit when physical windows are not ready for the CPU.
	This event indicates a wrong configuration of the CBUFF, the OCPI initiator or bogus software. When it happens, context i goes into an error state. In this state all accesses to the virtual space of context i are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory. Of course, the CBUFF still returns OCP responses to OCPI to ensure the integrity of the OCP.
	The error state can be left by disabling the context i and re-enabling it. Before doing so, software must ensure that there are no more outstanding requests to the virtual space of context i.
IRQ_CTXx_OVR	Physical space overflow or underflow event  This event indicates a bandwidth mismatch between data producer and data consumer. When it happens, context i does not go into error state. However, the data in the physical space is likely to be corrupted.
IRQ_OCP_ERR	OCP error received in the OCPO master port. The OCP response is forwarded to OCPI normally.

### 8.2.8.3 ISS CBUFF Functional Description

The CBUFF maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

#### 8.2.8.3.1 ISS CBUFF Features

The ISS CBUFF features are:

- Fully transparent for accesses out of the configured virtual space
- Three functional modes:
  - Read mode: Read requests received from OCPI and forwarded after translation to OCPO. Writes are handled by an external process and acknowledged by the CPU.
  - Write mode: Write request received from OCPI and forwarded after translation to OCPO. Reads are handled by an external process and acknowledged by the CPU.
  - Read/write mode: Read and write requests received from OCPI and forwarded after translation to OCPO
- Four independent contexts
- Virtual address space (linear) mapped into a physical space (circular)
- Maximum physical buffer size of 16 × 16MB:
  - Physical space consists of 2, 4, 8, or 16 windows.
  - Maximum allowed window size is 16MB.
- Support of 2D addressing modes
- Strong error detection mechanisms to prevent data corruption caused by bogus configuration
- Addresses are 128-bit aligned, but window fill level managing is byte accurate
- Bandwidth control feedback loop to stall in initiator connected to OCPI

#### 8.2.8.3.2 ISS CBUFF Functional Description

The CBUFF maps a virtual address space to a physical space also called circular buffer.

The CBUFF can handle up to eight contexts. For most data formats, primarily four contexts are used. In cases where YUV4:2:0 data is exchanged, two contexts are consumed by the SIMCOP (JPEG encode) coming from the resizer module, which is the ISP output module. Moreover, a context is a virtual full-frame buffer that maps to a configurable number of physical windows.

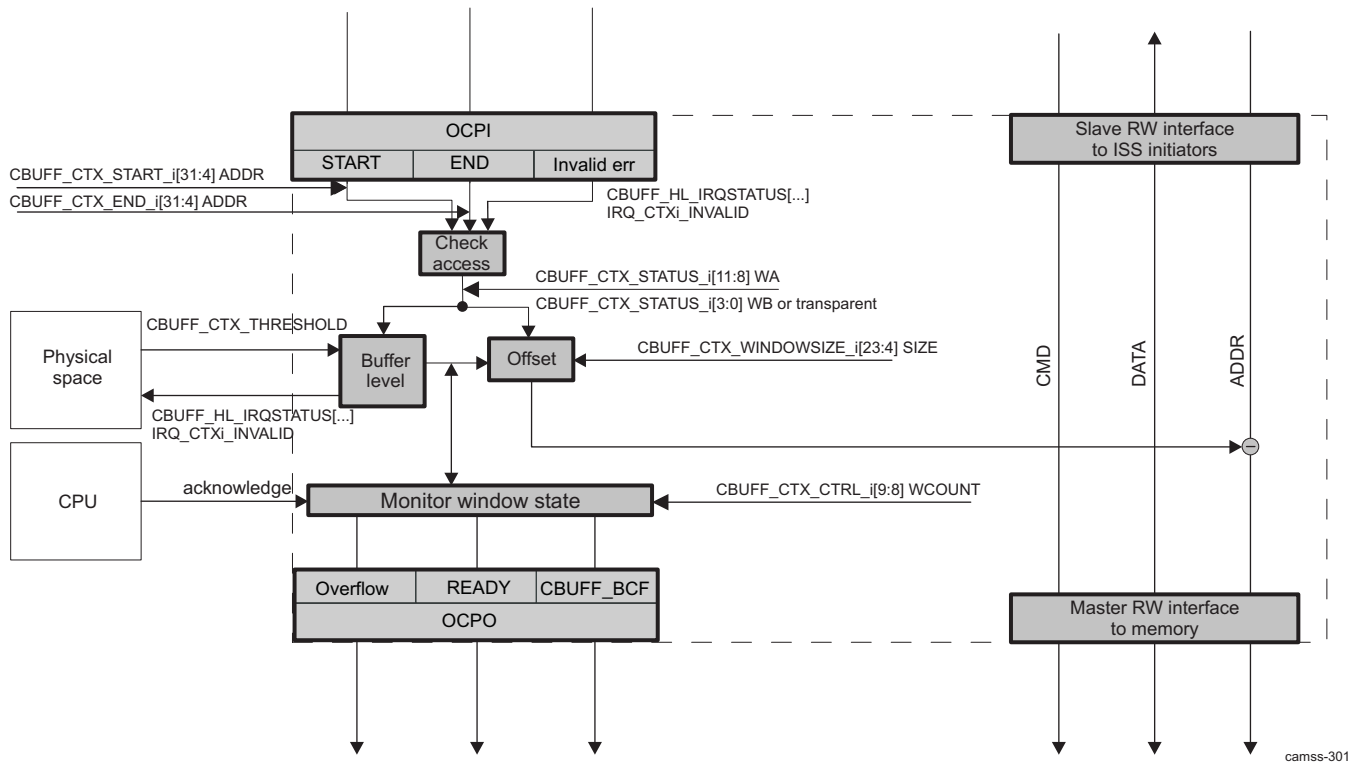

This section gives an overview of typical uses of the CBUFF.

**8.2.8.3.2.1 ISS CBUFF Top-Level Diagram**

Figure 8-92 shows the functional principle diagram. It does not include an exhaustive list of the interface signals or internal status registers.

A more detailed functional description is provided in the following sections.

**Figure 8-92. ISS CBUFF Top-Level Diagram**

camss-301

**8.2.8.3.2.2 ISS CBUFF Functional Modes**

The CBUFF supports three functional modes (see Table 8-269).

**Table 8-269. ISS CBUFF Functional Modes**

Mode	Data Written by	Data Read by
Write mode	ISS initiator	CPU-controlled process
Read mode	CPU-controlled process	ISS initiator
Read/write mode	ISS initiator	ISS initiator

**8.2.8.3.2.2.1 ISS CBUFF Write Mode**

In write mode, the physical space is written by the CBUFF and it is read by the CPU. An IRQ\_CTXx\_READY event is set each time a physical window is available to be read by the CPU. This happens when the CBUFF\_CTX\_STATUS\_i[11:8] WA pointer is moved by the CBUFF.

The CBUFF sets an IRQ\_CTXx\_READY event to inform the CPU that it can access the CBUFF\_CTX\_STATUS\_i[3:0] WB physical window. The CBUFF cannot monitor CPU accesses to the physical window. The CPU must indicate when it has completed the processing of the CBUFF\_CTX\_STATUS\_i[3:0] WB window by setting the CBUFF\_CTX\_CTRL\_i[2:1] DONE bit field. This increments the window index CBUFF\_CTX\_STATUS\_i[3:0] WB by one modulo the window count (defined by the CBUFF\_CTX\_CTRL\_i[9:8] WCOUNT bit field).

The CBUFF ensures that one `IRQ_CTXx_READY` event is sent to the CPU per physical window to be read. In other words, when a new `IRQ_CTXx_READY` event occurs before the previous one(s) is acknowledged by the CPU, it is not lost. The CBUFF memorizes the event and triggers the interrupt line again when the CPU clears it.

When the CPU reads the physical space too slowly, the `CBUFF_CTX_STATUS_i[11:8]` WA window pointer falls into the `CBUFF_CTX_STATUS_i[3:0]` WB window. This generates an `IRQ_CTXx_OVR` event when the OCPI initiator performs an access to that window. The CPU receives the `IRQ_CTXx_READY` event only if it is allowed to access a physical window. Therefore, it cannot generate an `IRQ_CTXx_OVR` event in a normal case. The OCPI initiator accesses are tracked based on activity on the OCP port.

When an `IRQ_CTXx_OVR` event occurs, the buffer content is likely to be corrupted. However, the CBUFF context continues processing data normally; it does not go into error state. Software must reset data generation and the CBUFF in a clean manner.

Figure 8-93 shows an example scenario with `CBUFF_CTX_CTRL_i[9:8]` `WCOUNT = 1` (four windows). In normal operation, the CPU processes data at least at the same speed as it is written to the physical space. When this is not true, the number of windows to be read by the CPU increases. When no more physical windows are available for OCPI writes, an overflow occurs.

In the previous example, the CPU takes more time than expected to read the third buffer. Therefore, physical windows are not freed up. The OCPI initiator continues to write data into the physical window. That leads to an overflow when the OCPI initiator writes into the physical window that is read by the CPU (`CBUFF_CTX_STATUS_i[11:8]` WA = `CBUFF_CTX_STATUS_i[3:0]` WB and writes into `CBUFF_CTX_STATUS_i[11:8]` WA detected).

**Figure 8-93. ISS CBUFF Write Mode CPU Interaction Example**

- (1) When there is no physical window available to be read by the CPU and the CPU writes the DONE bit, an `IRQ_CTXx_INVALID` event occurs.
- (2) The bandwidth control feedback (BCF) feature can be used to prevent overflow. It must be supported by the module writing data into the virtual space (typically, an ISS).

### 8.2.8.3.2.2 ISS CBUFF Read Mode

In read mode, the physical space is read by the CBUFF and it is written by the CPU. An `IRQ_CTXx_READY` event is set each time a physical window is available to be written by the CPU. This is true until all free buffers are used.

The CBUFF sets an `IRQ_CTXx_READY` event to inform the CPU that it can write the `CBUFF_CTX_STATUS_i[3:0]` WB window. The CBUFF cannot monitor CPU accesses to the physical space. It must indicate when it completes writing the `CBUFF_CTX_STATUS_i[3:0]` WB window by setting the `CBUFF_CTX_CTRL_i[2:1]` DONE bit field. This increments the CPU window index `CBUFF_CTX_STATUS_i[3:0]` WB by one modulo the window count (defined by the `CBUFF_CTX_CTRL_i[9:8]` `WCOUNT` bit field).

The CBUFF ensures that one IRQ\_CTXx\_READY event is sent to the CPU per physical window to be written. In other words, when a new IRQ\_CTXx\_READY event occurs before the previous one(s) is acknowledged by the CPU, it is not lost. The CBUFF memorizes the event and triggers the interrupt line again when the CPU clears it.

The following is an example of a normal operation in which the CPU writes data faster than it is read by the OCPI initiator. Figure 8-94 uses two physical windows (CBUFF\_CTX\_CTRL\_i[9:8] WCOUNT = 0).

**Figure 8-94. ISS CBUFF CPU Writes Data Faster Than it Is Read by the OCPI Initiator**

Software must enable the ISS initiator only when at least one window is written by the CPU. Otherwise, an OVERFLOW event occurs when BCF is not used.

The CPU receives an interrupt each time a physical window is available to receive data. It clears the interrupt and then starts filling the physical window. When the buffer is completely written, it sets the CBUFF\_CTX\_CTRL\_i[2:1] DONE bit field. This happens before the OCPI initiator has read all data from the previous physical window: the CPU must wait until the next IRQ\_CTXx\_READY event is received before it can write again to the physical space.

When the CPU writes buffers too slowly, the CBUFF\_CTX\_STATUS\_i[11:8] WA window falls into the CBUFF\_CTX\_STATUS\_i[3:0] WB window. This generates an IRQ\_CTXx\_OVR event only when the OCPI initiator performs reads to that window. The CPU receives the IRQ\_CTXx\_READY event only if it is allowed to access a physical window. Therefore, it does not generate an IRQ\_CTXx\_OVR event in a normal case. ISS accesses are tracked based on activity on the OCPI port.

When no buffer is available to be written by the CPU and the CPU writes the DONE bit, an IRQ\_CTXx\_INVALID event occurs.

When an IRQ\_CTXx\_OVR event occurs, the OCPI initiator reading the virtual space is likely to receive dummy data. However, the CBUFF context continues to process data normally; it does not go into error state. Software must reset the data consumer (OCPI initiator) and CBUFF context in a clean manner.

Figure 8-95 is an example of CBUFF read mode CPU interaction.

**Figure 8-95. CBUFF Read Mode CPU Interaction Example**

The BCF feature can be used to prevent overflow. It must be supported by the module reading data from the virtual space (typically, an ISS).

### 8.2.8.3.2.2.3 ISS CBUFF Read/Write Mode

Reads and writes are performed by OCPI initiators such as a camera interface, ISP, or SIMCOP. Address translation is performed for read and write data flows. The WA pointer is used for the write data flow, and the WB pointer is used for the read data flow. Therefore, address translation for the write data flow is the same as for write mode.

In this mode, the OCPI read data flow is stalled when there is not enough data to read in the physical space. A typical application is to store data from the camera in a CBUFF and to read it back by the ISP. When the camera is slower than the ISP, the ISP stalls.

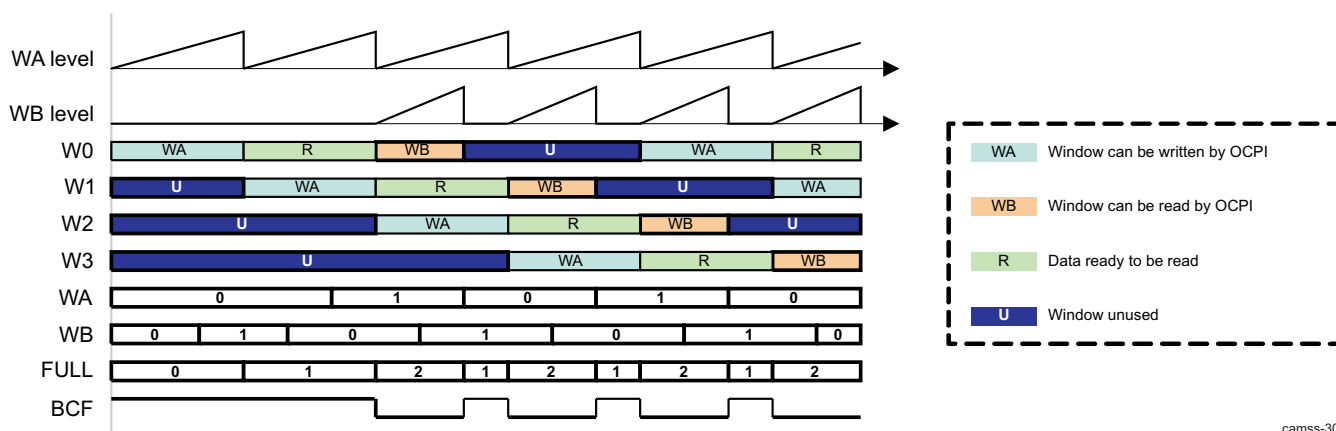

This mode does not rely on CPU synchronization. Synchronization is always performed using the BCF hardware mechanism. IRQ\_CTXx\_READY events are triggered in this mode when the OCPI write initiator has filled a physical window. Software can use this event for debug or performance bench marking purposes. Writes to the CBUFF\_CTX\_CTRL\_i[2:1] DONE bit field are ignored in this mode.

The IRQ\_CTXx\_OVR event is triggered when an underflow occurs. In a normal case this should not occur, because the BCF signal is used to stall the read data flow when insufficient data is available in the physical space.

Figure 8-96 assumes:

- Read/write mode
- Four physical windows
- CBUFF\_CTX\_THRESHOLD\_S\_i = CBUFF\_CTX\_THRESHOLD\_F\_i
- The OCPI read initiator is faster than the OCPI write initiator. The BCF feature is used to stall the read initiator. CBUFF\_CTX\_CTRL\_i[7:4] BCF = 2

Figure 8-96. ISS CBUFF Read/Write Mode Example

camss-305

### 8.2.8.3.2.3 ISS CBUFF Events and Status Checking

#### 8.2.8.3.2.3.1 ISS CBUFF Operations

A CBUFFx\_READY\_IRQ event is generated each time the CPU can read data from the CBUFF. The CPU can clear the event when it starts processing the data to avoid masking other events. The CPU can keep track of the location on the data internally or use the CBUFF registers to compute it.

The formula used is: ADDR = CBUFF\_CTX\_STATUS\_i[3:0] WB CBUFF\_CTX\_WINDOWSIZE\_i + CBUFF\_CTX\_PHY\_i

When the CPU is done with processing, it must free the buffer by setting the CBUFF\_CTX\_CTRL\_i[10] DONE bit. Otherwise, an overflow event may occur.

The CBUFF does not keep track of EOF events. They must be managed by the CPU using the EOF event of the module that writes into the CBUFF. At the EOF, data may remain in the current write windows. For example, when the window size is set to 8 lines and the image size is 20 lines, only two window-ready events are generated for a linear addressing scheme. The remaining four lines can be read after the EOF event.

No automatic reset of the CBUFF FSM occurs at the end of the image frame. Software must reset the context by clearing the [CBUFF\\_CTX\\_CTRL\\_i\[0\] ENABLEABLE](#) bit when the frame is completely processed. A new frame can start only when the [CBUFF\\_CTX\\_CTRL\\_i\[0\] ENABLEABLE](#) bit is set.

#### **8.2.8.3.2.3.2 ISS CBUFF Status Checking**

The CBUFF provides read-only access to the [CBUFF\\_CTX\\_STATUS\\_i\[11:8\]](#) WA and [CBUFF\\_CTX\\_STATUS\\_i\[3:0\]](#) WB pointers through the [CBUFF\\_CTX\\_STATUS\\_i](#) register. For example, the [CBUFF\\_CTX\\_STATUS\\_i\[3:0\]](#) WB index can be used by the CPU to compute the address of a physical window. Those indexes can also be used to evaluate latency margins.

#### **8.2.8.3.2.3.3 ISS CBUFF Register Accessibility During Frame Processing**

All registers are busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantly. However, module behavior is unpredictable when registers are changed during processing.

For correct operation, software must:

1. Disable all accesses to the virtual space managed by the context.
2. Disable the context by clearing the [CBUFF\\_CTX\\_CTRL\\_i\[0\] ENABLEABLE](#) bit.
3. Change the configuration.
4. Re-enable CBUFFx by setting the [CBUFF\\_CTX\\_CTRL\\_i\[0\] ENABLEABLE](#) bit.

#### **8.2.8.3.2.4 ISS CBUFF Memory-to-Memory Operation BCF**

The BCF mechanism matches the bandwidth between two processes.

The BCF feature can be used in all three CBUFF modes:

- Read mode: A CPU-controlled process writes data into physical space. The BCF signal is deasserted when the physical space contains enough data to start the read initiator connected to OCPI.
- Write mode: The BCF signal controls the write initiator connected to OCPI. When the CPU-controlled process does not read the data fast enough from the physical space, the BCF signal is asserted to stall filling of the buffer. It is deasserted when enough space is available in the physical space.
- Read/write mode: The BCF signal controls the read initiator connected to OCPI. Another initiator connected to OCPI fills the physical space. The BCF signal is deasserted when the physical space contains data that can be read by the read initiator. It is deasserted when insufficient data is available in the physical space.

The CBUFF\_BCF output is controlled based on two factors:

- The window count available for the OCPI initiator to read/write
- The amount of data in the last available window (pretrigger)

The CBUFF\_BCF signal is enabled by the [CBUFF\\_CTX\\_CTRL\\_i\[7:4\]](#) BCF bit field. It defines:

- Write mode: The amount of required free windows to allow writing from the ISS. In other words, when less than the required amount of BCF windows is available for ISS writes, the stall mechanism is triggered. The number of free windows is initialized to the total window count of the context. It is decreased by 1 each time the OCPI initiator finishes writing a window. It is increased by 1 each time the CPU finishes reading a window.
- Read and read/write modes: The minimum amount of required full windows to allow reading from the OCPI. When fewer than [CBUFF\\_CTX\\_CTRL\\_i\[7:4\]](#) BCF windows are available for ISS read, the stall mechanism is triggered. The number of full windows is initialized to 0. It is decreased by 1 each time the OCPI initiator completes reading a window. It is increased by 1 each time the CPU/OCPI initiator finishes writing a window.

Figure 8-97 is an example of BCF use. It assumes:

- Write mode: OCPI writes data into physical space and the CPU reads it.
- Two physical windows
- $CBUFF\_CTX\_THRESHOLD\_S\_i = CBUFF\_CTX\_THRESHOLD\_F\_i$
- The OCPI write initiator is faster than the CPU.
- $CBUFF\_CTX\_CTRL\_i[7:4] BCF = 1$

**Figure 8-97. ISS CBUFF Write Mode CPU Interaction Example BCF Used**

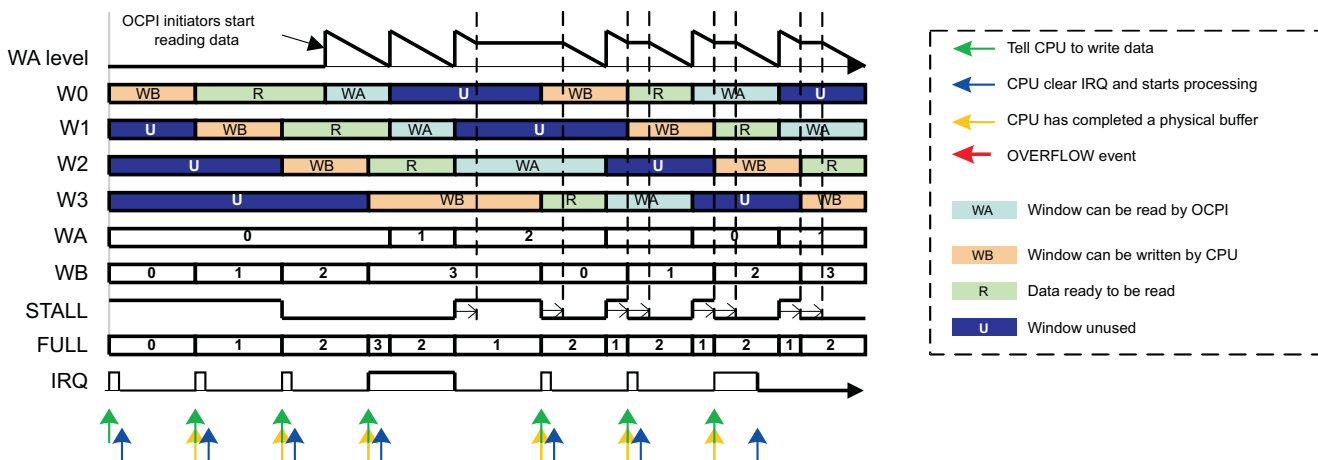

camss-307

Figure 8-98 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Four physical windows
- $CBUFF\_CTX\_THRESHOLD\_S\_i = CBUFF\_CTX\_THRESHOLD\_F\_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF\_CTX\_CTRL\_i[7:4] BCF = 2$

**Figure 8-98. ISS CBUFF Read Mode CPU Interaction Example (1)**

camss-308

Figure 8-99 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Two physical windows
- $CBUFF\_CTX\_THRESHOLD\_S\_i = CBUFF\_CTX\_THRESHOLD\_F\_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF\_CTX\_CTRL\_i[7:4] BCF = 1$

Figure 8-99. ISS CBUFF Read Mode CPU Interaction Example (2)

Figure 8-100 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Four physical windows
- $CBUFF\_CTX\_THRESHOLD\_S\_i = CBUFF\_CTX\_THRESHOLD\_F\_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF\_CTX\_CTRL\_i[7:4] BCF = 1$

CBUFF supports pretriggering the BCF signal for finer latency compensation control. This mechanism is active only for the last window available for OCPI access. It typically improves the physical space use, which is particularly useful when on-chip SRAM is used as a ping-pong buffer.

Pretriggering is controlled through the  $CBUFF\_CTX\_THRESHOLD\_S\_i$  register. It defines:

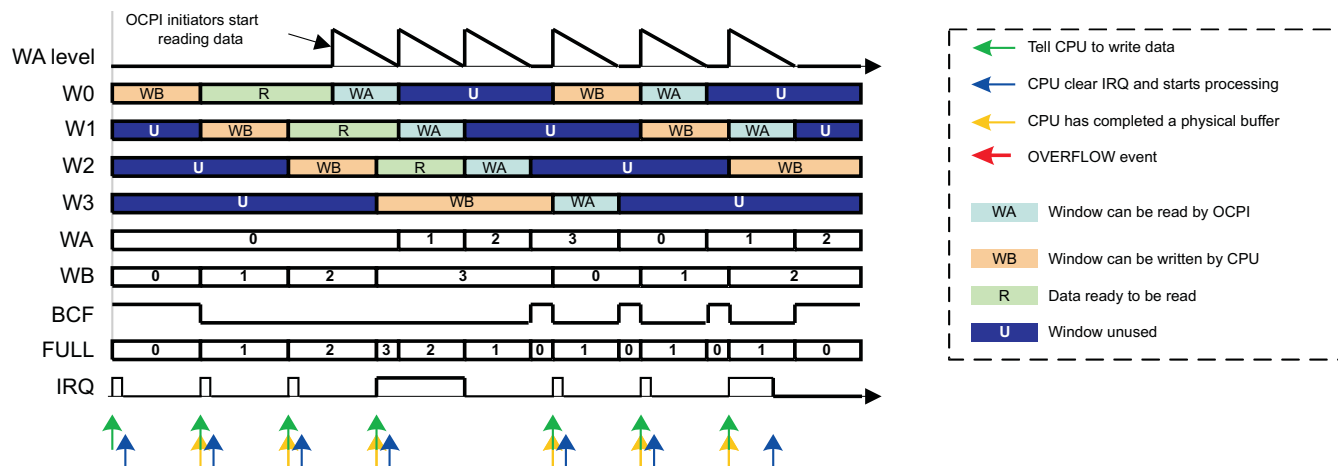

- Write mode: When the fill level of the last window available for ISS writes is greater than or equal to  $CBUFF\_CTX\_THRESHOLD\_S\_i$ , the  $CBUFF\_BCF$  signal is asserted.
- Read mode: When the amount of data in the last window available for ISS reads is less than  $CBUFF\_CTX\_THRESHOLD\_F\_i / CBUFF\_CTX\_THRESHOLD\_S\_i$ , the  $CBUFF\_BCF$  signal is asserted.

BCF pretriggering is disabled by setting  $CBUFF\_CTX\_THRESHOLD\_S\_i = CBUFF\_CTX\_THRESHOLD\_F\_i$ .

Figure 8-100 is an example of BCF pretriggering, assuming the following:

- Write mode: The CPU reads data from the physical space and the OCPI writes it.
- Two physical windows
- $CBUFF\_CTX\_THRESHOLD\_S\_i = 1/3 CBUFF\_CTX\_THRESHOLD\_F\_i$
- $CBUFF\_CTX\_CTRL\_i[7:4] BCF = 1$

**Figure 8-100. ISS CBUFF BCF Pretrigger Example: Write Mode**

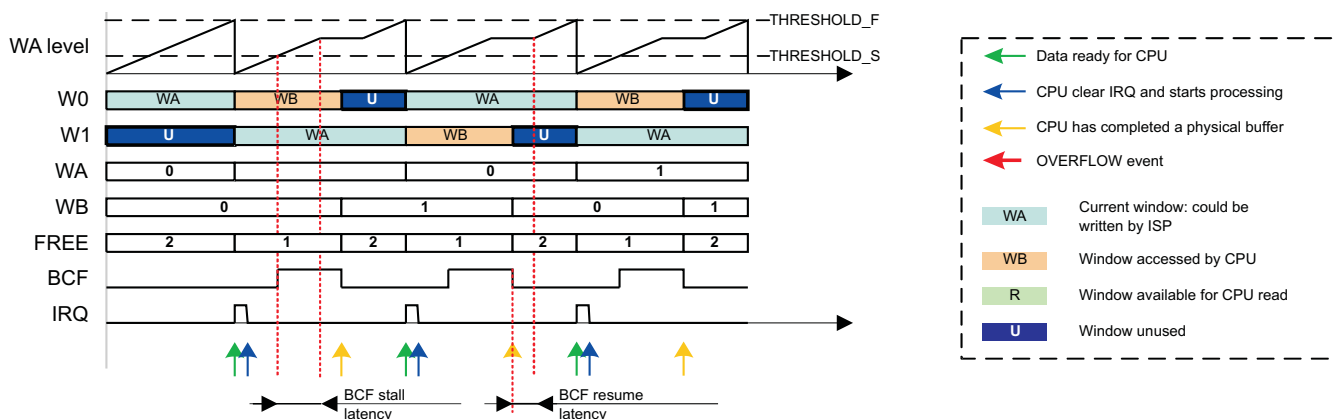

camss-310

The CBUFF\_BCF output signal is a logical OR of all internal BCF signals of CBUFF contexts. For example, when contexts 0 and 1 have enabled the BCF feature, both contexts can request a data flow stall.

Figure 8-101 is an example of pretriggering in read mode:

- Read mode: CPU writes data into the physical space and the OCPI reads it.
- Four physical windows
- $CBUFF\_CTX\_THRESHOLD\_S\_i = 2/3 CBUFF\_CTX\_THRESHOLD\_F\_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF\_CTX\_CTRL\_i[7:4] BCF = 2$

**Figure 8-101. ISS CBUFF BCF Pretrigger Example: Read Mode**

camss-311

### 8.2.8.3.2.5 ISS CBUFF TILER Support

The CBUFF can translate 2D (BLOCK) bursts intended for the TILER. However, software must ensure that a given burst fits in a window.

The expected value for ADDR[32] is defined by the  $CBUFF\_CTX\_CTRL\_i[11]$  TILERMODE bit.

- When  $ADDR[32] = CBUFF\_CTX\_CTRL\_i[11]$  TILERMODE, the access is processed normally. ADDR[32] is not used for further processing.
- Otherwise, the access is treated as transparent.

### 8.2.8.3.2.6 ISS CBUFF Window Management and Address Remapping Details

This section explains the internal address remapping and windows management algorithm. Internally, the module maintains some variables in addition to the configuration registers. The module manages multiple contexts in parallel. [Table 8-270](#) lists the CBUFF internal variables.

**Table 8-270. ISS CBUFF Internal Variables**

Variable	Description
WAX	Current window index for context x. Possible values are 0 to allowed window count. The current value can be read using the <a href="#">CBUFF_CTX_STATUS_i[11:8]</a> WA bit field.
WBx	Window in the physical space that can be accessed by the CPU in read/write modes. Window that is read from OCPI in read/write mode. Possible values are 0 to allowed window count. The current value can be read using the <a href="#">CBUFF_CTX_STATUS_i[3:0]</a> WB bit field.
VPAX	Start address, in the virtual space, of the <a href="#">CBUFF_CTX_STATUS_i[11:8]</a> WA window
	Used as a base pointer for the read (read mode) or write data flow (write, read/write modes)
	This is an internal quantity that cannot be accessed by software.
VPBx	Start address, in the virtual space, of the <a href="#">CBUFF_CTX_STATUS_i[3:0]</a> WB window
	Used as a base pointer for the read data flow.
	This is an internal quantity that cannot be accessed by software.
OFFSETAx	This is an internal quantity that cannot be accessed by software.
OFFSETBx	Address offset used when WAX or WBx is accessed
LEVELAx	This is an internal quantity that cannot be accessed by software.
LEVELBx	Address offset used when WAX or WBx is accessed

#### 8.2.8.3.2.6.1 ISS CBUFF Startup

The status of a CBUFF context is reset when it is disabled. This does not affect the configuration registers or the CBUFF\_IRQSTATUS register. [Table 8-271](#) lists the internal state after reset.

**Table 8-271. ISS CBUFF Internal State After Reset**

Variable	Description
WAX	0
WBx	0
VPAX VPBx	<a href="#">CBUFF_CTX_START_i</a>
OFFSETAx OFFSETBx	<a href="#">CBUFF_CTX_START_i</a> – <a href="#">CBUFF_CTX_PHY_i</a>
LEVELAx LEVELBx	0

#### 8.2.8.3.2.6.2 ISS CBUFF Access Identification

For each access to the virtual space (OCPI slave port), the CBUFF first checks the address to classify the transaction into one of the categories listed in [Table 8-272](#).

**Table 8-272. ISS CBUFF Address identification**

Address ID	Variable	Condition
0+2*x	WA_CBUFFx	<a href="#">CBUFF_CTX_CTRL_i[0]</a> ENABLE = 1 and ADDR >= VPAX and ADDR < VPAX + <a href="#">CBUFF_CTX_WINDOWSIZE_i</a> and ADDR <= <a href="#">CBUFF_CTX_END_i</a> and Access type = write when read/write mode is selected
1+2*x	WB_CBUFFx	<a href="#">CBUFF_CTX_CTRL_i[0]</a> ENABLE = 1 and <a href="#">CBUFF_CTX_CTRL_i[2:1]</a> MODE = 2 and

**Table 8-272. ISS CBUFF Address identification (continued)**

Address ID	Variable	Condition
		Access type = read and ADDR >= VPBx and ADDR < VPBx + CBUFF_CTX_WINDOWSIZE <sub>i</sub> and ADDR <= CBUFF_CTX_END <sub>i</sub>
16+x	ERR_CBUFFx	CBUFF_CTX_CTRL <sub>i</sub> [0] ENABLE = 1 and ADDR >= CBUFF_CTX_START <sub>i</sub> and ADDR <= CBUFF_CTX_END <sub>i</sub>
24	TRANSPARENT	Always true

Lower IDs correspond to higher priorities if multiple conditions are true. For example, when the current virtual window of CBUFF 0 is accessed, at least the tests for categories WA\_CBUFFx and ERR\_CBUFFx are true. The final category is WA\_CBUFFx, because it has a higher priority.

**NOTE:** Tests must be performed in parallel to match the desired performance.

Further processing depends on the category:

- TRANSPARENT: Accesses flow through the module without changing its internal state or any translation.
- ERR\_CBUFFx: The module goes into error state for the concerned context and sets the CBUFF\_HL\_IRQSTATUS.IRQ\_CTXx\_INVALID bit. When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between CBUFF\_CTX\_START<sub>i</sub> and CBUFF\_CTX\_END<sub>i</sub> is not transmitted to the OCPO master port. There are two ways to leave the error state:
  - Hardware reset
  - Disable and re-enable the context in error state.
 Accesses outside of the virtual space from the context in error state are not affected.
- WA\_CBUFFx and WB\_CBUFFx: The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read, write, or read/write mode). Otherwise, a CBUFF\_HL\_IRQSTATUS.IRQ\_CTXx\_INVALID event is set and CBUFFx goes into the error state.

### 8.2.8.3.2.6.3 ISS CBUFF Address Translation

An offset is selected depending on the access category (see [Section 8.2.8.3.2.6.1, ISS CBUFF Startup](#)) and the internal state of the accessed buffer. [Table 8-273](#) lists possible cases.

**Table 8-273. ISS CBUFF Address Translation**

Condition	Address Translation
CBUFF_CTX_CTRL <sub>i</sub> [0] ENABLE = 1 and ADDR >= CBUFF_CTX_START <sub>i</sub> and ADDR <= CBUFF_CTX_END <sub>i</sub> and CBUFFx in error state	Access cancelled
Category = WA_CBUFFx	ADDRROUT = ADDRIN-OFFSETAx
Category = WB_CBUFFx	Read/write mode only ADDRROUT = ADDRIN-OFFSETBx
Category = ERR_CBUFFx	Access cancelled
Category = TRANSPARENT	ADDRROUT = ADDRIN

### 8.2.8.3.2.6.4 ISS CBUFF Window Fill Level

Each time an access is performed into an active window (WA\_CBUFF<sub>x</sub> when context x is enabled) the window level is updated. The corresponding LEVEL<sub>y</sub> is incremented according to the BYTEEN input of the OCPI slave port. All possible BYTEEN patterns, including nonaligned ones, are supported. Table 8-274 shows some examples. The basic idea is to count the number of 1s in the BYTEEN input for each 128-bit word and to sum the values.

**Table 8-274. ISS CBUFF Window-Level Increment**

BYTEEN	LEVEL <sub>y</sub> Increment	Comment
0x0000	0	No access
0x0001	1	8-bit access
0x0002	1	8-bit access
0x0003	2	16-bit access
...	...	...
0x0007	3	24-bit access
...	...	...
0x000F	4	32-bit access
...	...	...
0x00F0	4	32-bit access
...	...	...
0xFFFF	16	128-bit access

The window level is compared to CBUFF<sub>x</sub>\_THRESHOLD. Table 8-275 lists the situations that may occur:

**Table 8-275. ISS CBUFF Window-Level Comparison<sup>(1)</sup>**

Condition	Description
LEVEL <sub>Ax</sub> >= CBUFF_CTX_THRESHOLD_F <sub>i</sub>	The CBUFF_CTX_STATUS <sub>i</sub> [11:8] WA bit field of context x is full (write mode) or empty (read mode). Internal window indexes, levels, and offsets are updated.
LEVEL <sub>Bx</sub> >= CBUFF_CTX_THRESHOLD_F <sub>i</sub>	Read/write mode only Window used to handle the read flow of context x is empty. Internal window indexes, levels, and offsets are updated.

<sup>(1)</sup> All situations described in Table 8-275 are mutually exclusive because only one level is updated each cycle.

### 8.2.8.3.2.6.5 ISS CBUFF Window Pointer and Offset Update

The following description refers to the update of WA in write mode:

When the current window of a context is full:

- A new window is opened. The update is done in a circular manner: the first physical window is reused after the last one.
  - WA (WA + 1) modulo the number defined by CBUFF\_CTX\_CTRL<sub>i</sub>[9:8] WCOUNT
  - LEVEL<sub>A</sub> <- 0
  - VPA <- VPA + CBUFF\_CTX\_WINDOWSIZE<sub>i</sub>
- When the window is moved from the last buffer to the first:
  - OFFSET<sub>A</sub> <- OFFSET<sub>A</sub> + CBUFF\_CTX\_WINDOWSIZE<sub>i</sub> << (CBUFF\_CTX\_CTRL<sub>i</sub>[9:8] WCOUNT + 1)
- Otherwise, OFFSET<sub>A</sub> does not change.

The algorithm used to update WA in read mode is the same, except that *full* refers to *all data of the window has been read or window empty*.

For read/write mode, the same algorithm is used to translate reads to the WBx window. Make the following changes:

- Replace WA with WB.
- Replace LEVELA with LEVELB.
- Replace VPA with VPB.
- Replace OFFSETA with OFFSETB.

#### 8.2.8.3.2.7 ISS CBUFF Error State

Contexts may go into error state when they receive unexpected accesses. In that case, the CBUFF does not send dummy transactions to the OCPO port. It does not forward the failing transactions to OCPO and returns valid responses (SResp = DVA) on OCPI to preserve the integrity of the OCP.

Responses may be received on OCPO while the CBUFF responds to failing transactions on OCPI. The OCPO response phase is stalled (MRespAccept = 0) during that time to prevent corruption. OCPO cannot be stalled longer than one full OCP transaction. Responses received on OCPO are handled before another internally generated response can be sent back to the OCPI. In that case, command and data phases are eventually stalled. Not stalling OCPO for too long is required to avoid affecting system performance.

During normal operation (that is, no context is in error state), the OCPO response phase is never stalled.

#### 8.2.8.3.2.8 ISS CBUFF Typical Configurations

##### 8.2.8.3.2.8.1 ISS CBUFF Single-Slice Buffer

An OCP master (typically, the ISS) writes data with an incremental addressing scheme to the virtual space. The physical space is smaller than the virtual space. Therefore, physical space locations are read and written multiple times. [Figure 8-102](#) shows the CBUFF single-slice buffer in write mode.

**Figure 8-102. ISS CBUFF Single-Slice Buffer (Write Mode)**

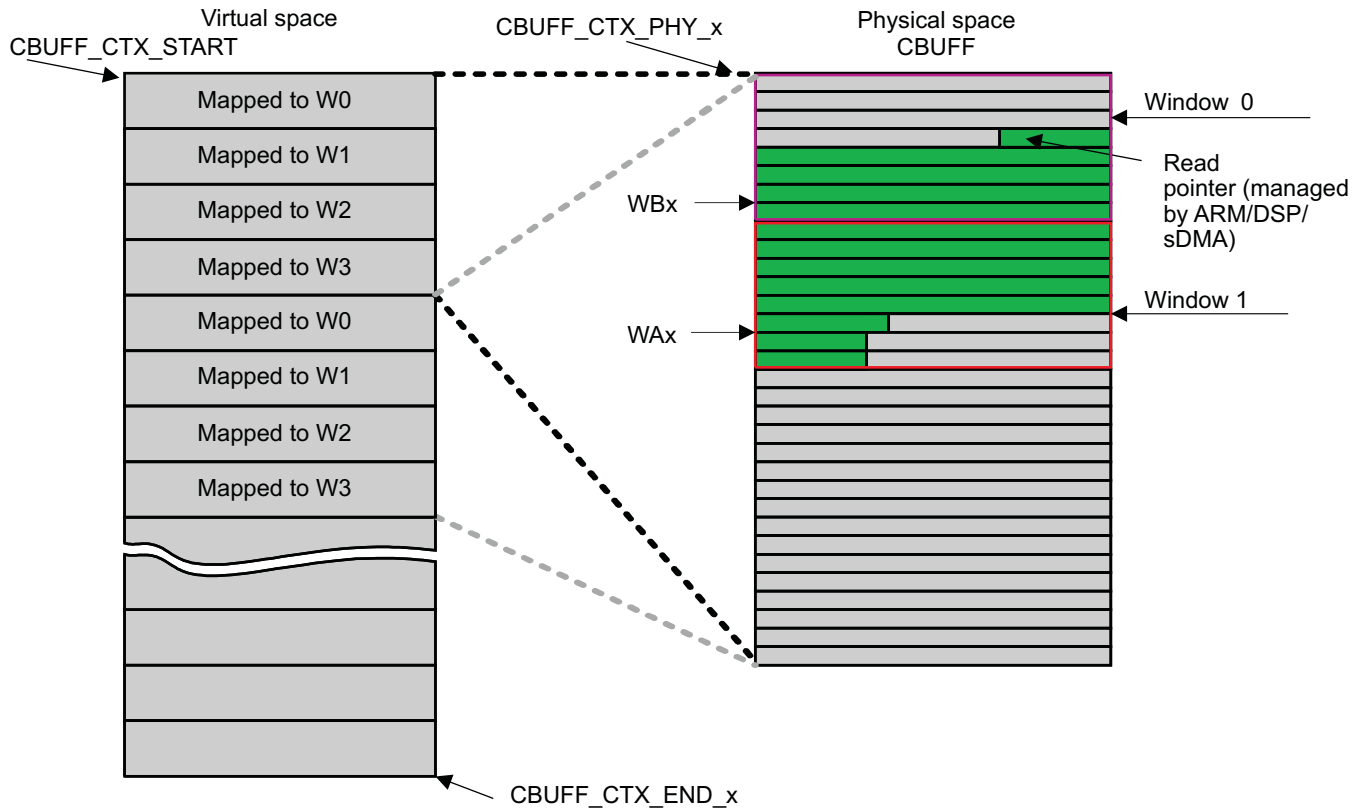

camss-313

Physically, this CBUFF is in on-chip SRAM or SDRAM. The virtual space is defined by a start and end addresses. The physical space is defined by a start address, a window size, and a window count. It is contiguous in memory. When the CPU accesses physical memory for processing, it must know if the SDRAM is available for it to access and if the CBUFF is not using it. The CPU and CBUFF cannot track each other. For example, an interrupt must be triggered from the SIMCOP to the CBUFF to notify it when the processor is done working with SDRAM. For more information about the software configuration for these interrupts, see [Section 8.2.8.3.2.2.1, ISS CBUFF Write Mode](#).

Figure 8-103 shows the buffer organization for a 4-window buffer.

**Figure 8-103. ISS CBUFF Single-Slice Buffer Example (Write Mode)**

camss-314

The CBUFF can manage multiple contexts in single-slice mode.

### 8.2.8.3.2.8.2 ISS CBUFF Extended-Slice Buffer

In extended-slice mode, at least two contexts managed by the CBUFF are used together. The two contexts provide address translation, one for the read data flow and the other for a write data flow. Figure 8-104 is an example of the CBUFF extended-slice buffer.

**Figure 8-104. ISS CBUFF Extended-Slice Buffer Example**

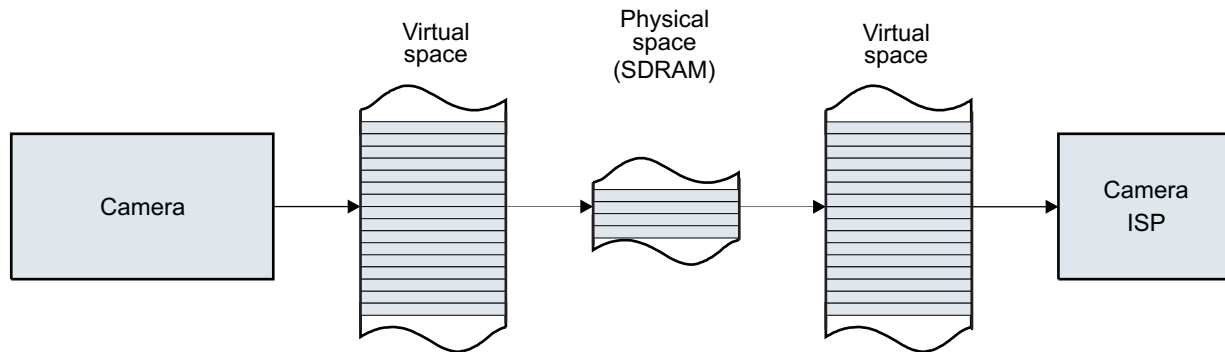

camss-315

### 8.2.8.3.2.9 ISS CBUFF FIFO Mode

The CBUFF can behave like a FIFO to buffer data between two initiators connected to the OCPI. A typical use case is a camera interface writing data to the FIFO and an ISP reading data from the FIFO. Figure 8-105 shows the CBUFF FIFO mode.

**Figure 8-105. ISS CBUFF FIFO Mode**

camss-316

The CBUFF is used as a FIFO when the camera provides data at a higher rate than the ISP can process. To avoid storing one or multiple full-frame buffers, a FIFO buffer is used to store the data that cannot be processed immediately.

For this example, assume that the camera provides 16 MPix at 15 frames per second at 200 Mhz. A new frame is provided every 66 ms. The ISP needs 80 ms to process this frame. Therefore, the processing cannot be done on the fly, and each other frame must be dropped.

Figure 8-106 shows the accumulated amount of data provided by the camera since the start of the frame; the amount of data consumed by the ISP since it has started processing the frame; and the difference between the two, which must be stored in the FIFO.

**Figure 8-106. ISS CBUFF FIFO Use Example**

camss-317

The FIFO is emulated as 16 windows (`CBUFF_CTX_CTRL_i[9:8] WCOUNT = 0x3`). The ISP is started by software when a few kilobytes of data are written to the physical space. Alternatively, the BCF mechanism can be used, but the minimum FIFO size is more complex to calculate.

The FIFO level reaches its maximum when the camera performs the last write of the frame. The camera provides the data at  $1 \text{ byte/pixel} \times 16 \text{ MPix}/60 \text{ ms} = 266 \text{ MBytes/s}$ . The ISP reads data at  $1 \text{ byte/pixel} \times 16 \text{ MPix}/80 \text{ ms} = 200 \text{ MBytes/s}$ . Therefore, the minimum FIFO size is  $60 \text{ ms} \times (266 \text{ MBytes/s} - 200 \text{ MBytes/s}) = 3.96 \text{ MBytes/s}$ , which is four times less than a full-frame buffer.

Each window holds 256KB of data. The camera starts writing to a new physical window every  $256\text{KB}/266 \text{ MBytes/s} = 962 \mu\text{s}$ . The ISP starts reading from a new physical window every  $1280 \mu\text{s}$ .

The FIFO mode can also be used when the ISP is slower than the camera. In that case, the ISP is stalled when insufficient data is available in the physical space.

## 8.2.8.4 ISS CBUFF Programming Model

### 8.2.8.4.1 ISS CBUFF Reset Behavior

Upon hardware or software reset of the CBUFF, all registers in the CBUFF are reset to their reset values

This software reset has the same effect as a hardware reset. ISS high-level software reset ensures that traffic is stopped on clear boundary because the CBUFF is sending data to and from other modules. ISS top-level reset is preferred. For more information about ISS software reset, see [Section 8.1.2.3, ISS Reset](#). Submodule reset is not preferred but is available through the following registers:

1. Set the [CBUFF\\_HL\\_SYSCONFIG\[0\] SOFTRESET](#) bit to 1.
2. Read the [CBUFF\\_HL\\_SYSCONFIG\[0\] SOFTRESET](#) bit to check whether it is set to 1, which means the reset occurred.

The reset is performed without waiting until all OCP traffic stops. To avoid OCP corruption, software must ensure there is no more ongoing traffic before performing a reset.

### 8.2.8.4.2 ISS CBUFF Register Setup

All registers of the context to be used must be initialized for correct operation. [Table 8-276](#) lists the procedure for the CBUFF register setup.

**Table 8-276. ISS CBUFF Setup Register**

Step	Bit Field	Value
Set operation mode.	<a href="#">CBUFF_CTX_CTRL_i[2:1] MODE</a>	0x0: Write mode 0x1: Read mode 0x2: Read/write mode 0x3: Reserved
Define the virtual address range managed by the CBUFF. It usually corresponds to the address region where one image frame is written by the OCPI initiator.	<a href="#">CBUFF_CTX_START_i</a> and <a href="#">CBUFF_CTX_END_i</a>	
Define the start address of the physical buffer.	<a href="#">CBUFF_CTX_PHY_i</a>	
Set the window count and size. The window size usually depends on the use of the buffer. Eight or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency-related overflow protection.	<a href="#">CBUFF_CTX_CTRL_i[9:8] WCOUNT</a> and <a href="#">CBUFF_CTX_WINDOWSIZE_i</a>	
When the 2D addressing capability is not used, set to the window size in <a href="#">CBUFF_CTX_THRESHOLD_F_i</a> . Otherwise, it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to lines by 4096 pixels, but the ISP sends lines of only 2560 pixels, <a href="#">CBUFF_CTX_WINDOWSIZE_i</a> = 8 4096 and <a href="#">CBUFF_CTX_THRESHOLD_F_i</a> = 8 2560.	<a href="#">CBUFF_CTX_THRESHOLD_F_i</a>	
BCF signal-generation configuration is optional.	<a href="#">CBUFF_CTX_THRESHOLD_S_i</a> and <a href="#">CBUFF_CTX_CTRL_i[7:4] BCF</a>	
Enable the module. It can be disabled by clearing the ENABLE bit. This must be done only when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the CBUFF are reset when it is disabled. Pending interrupts are not affected.	<a href="#">CBUFF_CTX_CTRL_i[0] ENABLE</a>	

## 8.2.8.5 ISS CBUFF Register Manual

### 8.2.8.5.1 ISS CBUFF Instance Summary

[Table 8-277](#) lists the CBUFF instance.

**Table 8-277. ISS CBUFF Instance Summary**

Module Name	L3 Base Address	Size

<b>Physical Address</b>	0x5200 1900 + (0x20 * i)	<b>Instance</b>	ISS_CBUFF
<b>Description</b>	Context control register		
<b>Type</b>	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																TILERMODE	DONE	WCOUNT	BCF				RESERVED	MODE	ENABLE						

Bits	Field Name	Description	Type	Reset
31:12	RESERVED		R	0x00000
11	TILERMODE	Sets the expected value for ADDR[32]. If ADDR[32]=TILERMODE, ADDR[31:4] is processed and eventually translated. Otherwise, the access is handled as transparent, regardless of the other address bits.	RW	0
10	DONE	Write this bit to 1 to indicate the CPU has finished processing its physical buffer. This bit is automatically cleared by hardware, reads always return 0. This bit has no effect when MODE=2 (read/write)  Write 0x0: No effect.  Write 0x1: The CPU has completely processed the WB physical buffer.	W	0
9:8	WCOUNT	Window count  0x0: 2 windows  0x1: 4 windows  0x3: 16 windows  0x2: 8 windows	RW	0x0
7:4	BCF	This register controls the bandwidth control feedback loop output. 0: Control loop disabled. 1-15: The control feedback loop enabled. Behavior depends on functional mode, see <a href="#">Section 8.2.8.3.2.4, ISS CBUFF Memory-to-Memory Operation BCF</a> .	RW	0x0
3	RESERVED		R	0
2:1	MODE	Selects the functional mode of this context  0x0: Write mode. ISS writes and CPU reads the physical space. CPU accesses are out of the scope of the CBUFF module; therefore, only writes are permitted between CBUFF_CTX_START__x and CBUFF_CTX_END__x.  0x1: Read mode. Hardware reads and CPU writes the physical space. CPU accesses are out of the scope of the CBUFF module; therefore, only reads are permitted between CBUFF_CTX_START__x and CBUFF_CTX_END__x.  0x2: Read/Write mode. Read and writes are monitored by the CBUFF. WB is used to track current read positions WA is used to track current write position.	RW	0x0

Bits	Field Name	Description	Type	Reset
0	ENABLE	Enable/disable  0x0: Disables the context. This resets the internal state of the context. All accesses received on OCPI are transmitted to OCPO without modification. Disabling the context takes effect immediately. Software must ensure that no more accesses to the context are outstanding before disabling it. Otherwise memory corruption may occur.  0x1: Enable the context. All accesses between CBUFF_CTX_START_x and CBUFF_CTX_END_x are processed by the CBUFF.	RW	0

## 8.3 ISS ISP

This section describes the image signal processor.

### 8.3.1 ISS ISP Overview

The image signal processor (ISP) is part of the image subsystem (ISS) of the device and is a key component for imaging and video applications. It describes all ISP modules in the multimedia device; that is, the video port (VP), pattern generator (PG), image pipe interface (IPIPEIF), image pipe module (IPIPE), resizer (RSZ), hardware 3A (H3A), image sensor interface (ISIF), and buffer logic (BL). For better understanding, see the first top-level ISS diagram and feature list in [Section 8.1, ISS Overview](#).

#### 8.3.1.1 ISS ISP Features

The video-processing hardware removes the need for expensive camera modules to perform processing functions. The ISS can support the following features:

- On-the-fly or memory-to-memory processing
- Up to 200-MHz pixel throughput.
- Statistic data collection:
  - On-the-fly or memory-to-memory operation
  - Data collection for auto exposure
  - Data collection for auto white balance
  - Data collection for auto focus
  - Boundary signal calculation for video stabilization
- IPIPE front end: RAW data processing:
  - On-the-fly or memory-to-memory processing
  - 16-bit-wide RAW BAYER data path between image and sensor linearization module
  - 12-bit-wide RAW BAYER data path between sensor linearization module and gamma correction module. Gamma correction module outputs 10-bit data.
  - Programmable Bayer RGB positions
  - Sensor data linearization for dynamic range extension
  - Programmable 2D lens shading compensation (LSC) correction
  - Per-pixel gain and offset control
  - Black level compensation
  - Boxcar filter
  - Data collection for histogram generation
  - Defect pixel correction (LUT\_DPC) with look-up table (LUT)
  - Defect pixel correction (OTF\_DPC) with on-the-fly detection and correction
  - 2D noise filtering
  - Green imbalance correction (GIC)
  - Digital gains and offset
  - 8- to 10-bit A-law decompression and 10- to 8-bit A-law compression
- IPIPE back end: RGB and YUV data processing:
  - RGB-to-RGB color correction
  - Gamma correction (GC).
  - RGB -> YUV4:2:2: Color conversion, cosited chroma filtering and downsampling
  - 2D edge enhancement (EE)
  - 3D LUT for color correction
  - False chroma suppression (FCS)
- Two resizers:
  - Performance: input and output rates up to 200 MPix/s

- YUV4:2:2 to RGB56, ARGB888, YUV4:2:2, and YUV4:2:0 data output
- YUV4:2:0 to YUV4:2:0 data output
- RAW to RAW data output
- Range from x1/4096 to x20. Supports memory-to-memory rescaling.

The ISP comprises the following modules:

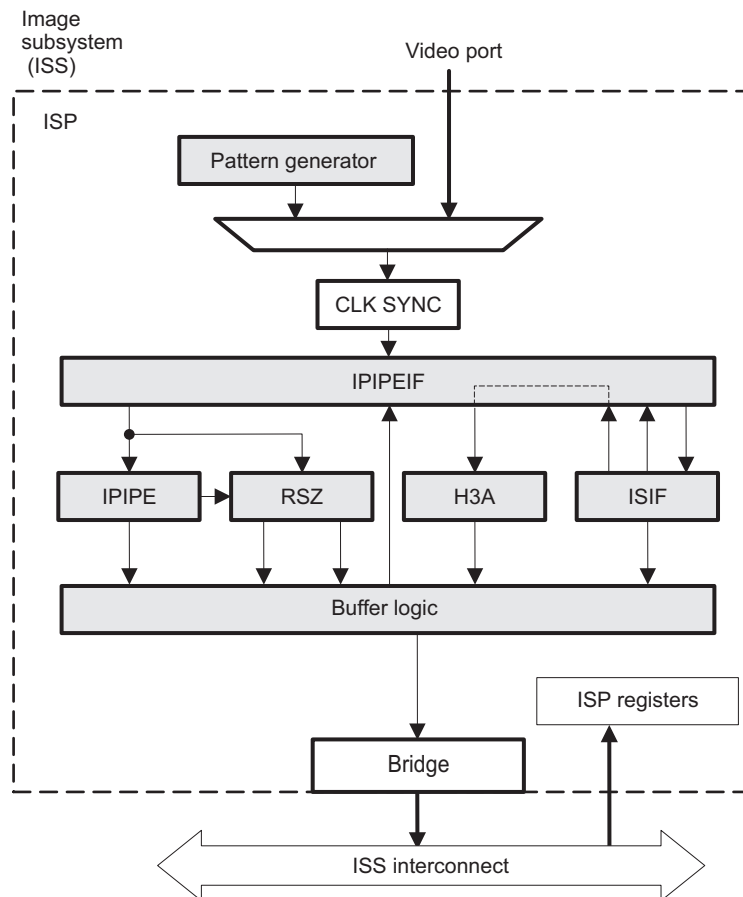

- Pattern generator (PG)
- IPIPE interface (IPIPEIF)
- Image sensor interface (ISIF) accelerator
- Auto exposure, auto white balance, and auto focus engine (H3A)
- Image pipe accelerator (IPIPE)
- Two resizer (RSZ) accelerators
- Buffer logic (BL): Receives module requests, performs arbitration, and creates read/write bursts to the memory subsystem

### 8.3.1.2 ISS ISP Block Diagram

Figure 8-107 is the ISP top-level block diagram. The ISS supports four simultaneous pixel flows (CCP2, CSI2 A, CSI2 B, and parallel interface [CPI]), but only one of them at a time can use the video-processing hardware; the others can go directly to memory (CPI must always use ISP).

The ISP master port is connected to the level 3 (L3) interconnect, and the slave port is connected to the level 4 (L4) interconnect.

Figure 8-107. ISS ISP Block Diagram

camss-003

### 8.3.2 ISS ISP Integration

This section describes the integration of the ISP modules in the ISS and includes information about clocks, resets, and hardware requests.

The ISP is part of the ISS of the device and is a key component for imaging and video applications such as camera viewfinder, video record, and still image capture.

ISS is coupled with a low interrupt latency ISS microprocessor unit (MPU) subsystem running a real-time operating system to reach optimal performance. Primarily, the ISS MPU subsystem can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks.

#### 8.3.2.1 ISS ISP PRCM Interface

The ISP and its internal modules, as integrated in the ISS, use the same power and clock management details. See [Section 8.1.2, ISS Functional Description](#), for the ISP top-level power, reset, and clock management (PRCM) Interface.

##### 8.3.2.1.1 ISS ISP Clocks

The PRCM module, through the local power and clock management inside the ISS, provides a unique PCLK that can be enabled from the [ISP5\\_CTRL](#) register.

The modules inside the ISP require three clocks:

- PCLK: This clock is asynchronous to the other clocks. It is provided by the module sending the data to the IPIPEIF module on the VP.
- ISS\_FCLK: This clock is synchronous with the configuration clock domain. This is the clock used for the MTC interface.
- GCK\_MMR: This is the clock for the configuration bus. It is created from the ISS\_FCLK and runs at half the speed of the ISS\_FCLK.

##### 8.3.2.1.2 ISS ISP Reset

The ISP supports global software reset along with internal hardware reset, if needed.

Software reset is done through the [ISP5\\_SYSCONFIG](#)[1] SOFTRESET bit. Before issuing a software reset, the ISP must be in standby mode. The following must be done:

1. Ensure that the interfaces are stopped from sending data and/or the ISP modules are disabled. Before reset, the last interrupt triggered by the ISP when the frame processing completes is RSZ\_INT\_DMA. RSZ\_INT\_DMA must be used to enable clean termination of the processing. Software must wait a few hundred cycles to trigger a soft reset after RSZ\_INT\_DMA is asserted; this is to ensure that the BL is completely drained.
2. Ensure that [ISP5\\_SYSCONFIG](#)[5:4] STANDBYMODE = 2 (smart standby). Write the [ISP5\\_CTRL](#)[24] MSTANDBY bit to 1 and poll for [ISP5\\_CTRL](#)[20] MSTANDBY\_WAIT = 1. Then, the soft reset can be applied ([ISP5\\_SYSCONFIG](#)[1] SOFTRESET = 1).

In case an ISP overflow event happens (for example, RSZ\_FIFO\_OVF, ISIF\_OVF, etc.), it is not sufficient to reset the ISP. In that case a reset must take place at the ISS level.

#### 8.3.2.2 ISS ISP Interrupt Tree

[Table 8-311](#) summarizes the submodule interrupts that can be mapped to the four ISP interrupt output lines. After this, these output lines are mapped to the ISS top interrupt request (IRQ) merger (for more information, see [Section 8.1.2](#)). Software enables the explained before merger from the top-level ISS resources registers in [Section 8.1.2](#).

### 8.3.2.3 ISS ISP PG Integration

See [Section 8.3.2](#), *ISS ISP Integration*.

### 8.3.2.4 ISS ISP IPIPEIF Integration

#### 8.3.2.4.1 ISS ISP IPIPEIF Interrupts

The IPIPEIF module generates two interrupts, one generic and one:

- IPIPEIF\_IRQ: This event is triggered to the BL module when a new frame starts (VS signal). The interrupt is active low and is asserted for one GCK\_MMR clock cycle.
- IPIPEIF\_UDF: Interrupt generated when an underflow happens in the IPIPEIF module. Underflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level.

The interrupts are enabled from the [ISP5\\_IRQENABLE\\_SET\\_i](#)[9] IPIPEIF\_IRQ and [ISP5\\_IRQENABLE\\_SET2\\_i](#)[1] IPIPEIF\_UDF bits (where  $i = 0$  to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

### 8.3.2.5 ISS ISP IPIPE Integration

#### 8.3.2.5.1 ISS ISP IPIPE Interrupts

IPIPE can generate several interrupts:

- IPIPE\_INT\_DPC\_RNEW: This event is triggered when there is permission to initialize LUT-DPC table lines 0 and 1.
- IPIPE\_INT\_DPC\_INI: This event is triggered when the defect pixel correction (DPC) table is initialized.
- IPIPE\_INT\_HST: This event is triggered when the histogram is done.
- IPIPE\_INT\_BSC: This event is triggered when boundary signal calculation is done.
- IPIPE\_INT\_DMA: This event is triggered when the boxcar SDRAM transfer is done. On this timing, IPIPE\_INT\_EOF is sent to the BL. This event is active high for one GCK\_MMR clock cycle.
- IPIPE\_INT\_LAST\_PIX: This event is triggered when the last pixel of a frame comes into IPIPE. This event is active high for one GCK\_MMR clock cycle.
- IPIPE\_INT\_EOF: This event is triggered for end of frame.
- IPIPE\_BOXCAR\_OVF: This event is generated when an overflow happens in the IPIPE-BOXCAR output buffer. The interrupt avoids polling the [IPIPE\\_SRC\\_STA](#)[0] VAL0 bit for errors. Overflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level.
- IPIPE\_HST\_ERR: This event is triggered when the MPU or system direct memory access (sDMA) is still reading the memory that is being used by the module. This is an indication that the read operation was not fast enough.

The interrupts are enabled from the [ISP5\\_IRQENABLE\\_SET\\_i](#) and [ISP5\\_IRQENABLE\\_SET2\\_i](#) registers (where  $i = 0$  to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

#### 8.3.2.5.2 ISS ISP DMA Requests

The ISP generally outputs four direct memory access (DMA) requests, which can be used to read or write memories inside the IPIPE module. These memories are:

- BSC memory: This memory must be read during a vertical blanking period. It is used by the video stabilization application.
- HIST memory: This memory must be read during a vertical blanking period. It is used by the 3A application. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the [IPIPE\\_HST\\_TBL](#)[0] SEL bit.
- GAMMA memory: This memory must be set during a vertical blanking period. The imaging application typically uses multiple gamma tables.
- DPC memory: This memory must be set during a frame acquisition. The memory is not big enough to store all faulty pixels for a given frame.

To generate the DMA requests, the following events must be used:

- The IPIPE\_INT\_BSC event is used to generate the DMA request for the BSC memory. It maps on DMA line 0, ISS\_DMA0.
- The IPIPE\_INT\_HST event is used to generate the DMA request for the HIST memory. It maps on DMA line 1, ISS\_DMA1. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the [IPIPE\\_HST\\_TBL](#)[0] SEL bit. When the DMA request is set, it is required to read 4KB from the ping buffer address (0x2000) or the pong buffer address (0x3000). Software must ensure that when one buffer is selected no other accesses (for example, MPU) take place in the other buffer.
- The IPIPE\_INT\_LAST\_PIX event is used to generate the DMA request for the GAMMA memory. This

same event can also be used to initialize the DPC LUT (not the preferred method; it is better to use IPIPE\_INT\_DPC\_INI). Basically, when the last pixel is output from the IPIPE module, it is safe to modify the IPIPE memories. It maps on DMA line 3, ISS\_DMA3.

- The IPIPE\_INT\_DPC\_INI event signals that DPC table memory initialization can take place. IPIPE\_INT\_DPC\_INI is used to generate two back-to-back DMA requests, the first one mapping on IPIPE\_INT\_DPC\_RNEW0 and the second one mapping on IPIPE\_INT\_DPC\_RNEW1. After initialization (steady state), the IPIPE\_INT\_DPC\_RNEW0 and IPIPE\_INT\_DPC\_RNEW1 events are used to generate the DMA request for the DPC LUT renewal. It maps on DMA line 2, ISS\_DMA2. To select which event is used to initialize the DPC (IPIPE\_INT\_LAST\_PIX or IPIPE\_INT\_DPC\_INI), set the [ISP5\\_CTRL\[25\] DPC\\_EVT\\_INI](#) bit.

---

**NOTE:** The size of the DPC table in SDRAM must be a multiple of the number of DMA requests. It ensures that during burst capture mode the DMA always loads the correct data from frame-to-frame. The DMA automatically warps back to the start of the table after all expected DMA requests are received. There is a total of  $\text{ceil}(\text{nb\_faulty\_pixel}/128) + 2$  DMA requests per frame when the IPIPE\_INT\_DPC\_INI EVENT is used. Hence, the size of the DPC table in the SDRAM is  $(\text{ceil}(\text{nb\_faulty\_pixel}/128) + 2) \times 128 \times 32$  bits.

---

**NOTE:** If DMA channels are not used but the MPU is used, an error check must be performed for IPIPE HST. See [ISP5\\_CTRL\[26\] HST\\_RD\\_CHK](#) for details.

---

The DMA request assertion and deassertion to the sDMA is automatic and no software intervention is needed. The ISP contains two registers ([ISP5\\_DMAENABLE\\_SET](#) and [ISP5\\_DMAENABLE\\_CLR](#)) that must be used to enable or disable generation of the DMA requests.

The DMA request deassertion is based on late deassertion; that is, the DMA request is disabled only when all the data corresponding to the transfer size have been read or written. To deassert the DMA request and generate the hw\_eoi signal, hardware counts the number of 32-bit accesses that are done in the memory range of the corresponding DMA request through the ISP slave port. When the number of accesses corresponding to the DMA request is done, the DMA request is cleared. Multiple DMA requests can be active simultaneously.

Software must not attempt to read or write in the memory range of the DMA requests that are enabled because CPU accesses, instead of sDMA accesses, will be counted. Software can freely access ISP memories for which the DMA request is disabled, and can access registers while the sDMA performs the transfers.

### 8.3.2.6 ISS ISP RSZ Integration

#### 8.3.2.6.1 ISS ISP RSZ PRCM Interface

##### 8.3.2.6.1.1 ISS ISP RSZ Reset

The resizer module has no standalone software reset. RSZ must be reset at the ISP level. See [Section 8.3.2.1.2, ISS ISP Reset](#).

##### 8.3.2.6.2 ISS ISP RSZ Interrupts

RSZ can generate several interrupts:

- RSZ\_INT\_EOF0: This event is triggered for end of frame.
- RSZ\_INT\_EOF1: This event is triggered for end of frame.
- RSZ\_FIFO\_IN\_BLK\_ERR: This event is triggered when the minimum vertical blanking period has not been respected, thus causing errors in the input data buffering submodule. This event is triggered when the RSZ\_INT\_REG event of frame N is triggered before RSZ\_INT\_DMA of frame N + 1. This event typically happens at the transition between two frames because there is not enough vertical blanking between frames. Hardware cannot recover from this error. It requires a reset. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are

completed and further requests are blocked.

- **RSZ\_FIFO\_OVF**: This event typically occurs while processing a frame, because the VP pixel clock is too high. Because hardware cannot recover from this error, a reset is required. It is a requirement that despite the error the RSZ module must finish correctly: ongoing requests are completed and further requests are blocked.

This event signifies overflow in the following scenarios:

- In Bypass or Operating (normal/downscale) modes, the **RSZ\_FIFO\_OVF** event is triggered when overflow occurs in the input circular data buffer. The **rsz\_stall\_input** signal can be asserted by programming appropriate thresholds to prevent input FIFO overflow.
- In Pass-through mode, the **RSZ\_FIFO\_OVF** event is triggered when overflow occurs in the output MTC buffer. There is no hardware mechanism to prevent overflow in Pass-through mode.
- **RSZ\_INT\_CYC\_RZA/RSZ\_INT\_CYC\_RZB**: This event is triggered as circular interrupt every time that **RSZ\_IRQ\_RZA/RSZ\_IRQ\_RZB** output lines are written out to the **RZA\_SDR\_Y/RZB\_SDR\_Y** buffer. The range can go from 1 to 8192 lines. Usually, this value must be such that the circular buffer vertical size (set by the **RZBA\_SDR\_Y\_PTR\_E/RZBB\_SDR\_Y\_PTR\_E** register) is a multiple of **RSZ\_IRQ\_RZA/RSZ\_IRQ\_RZA**.
- **RSZ\_INT\_DMA**: This event is triggered when the last EOF (of the two MTC interfaces) is sent out to the BL and the RSZ core returns to idle. This event is active high for one GCK\_MMR clock cycle.
- **RSZ\_INT\_LAST\_PIX**: This event is triggered when the last pixel of the valid area is received. This event is active high for one GCK\_MMR clock cycle.
- **RSZ\_INT\_REG**: This event is triggered when the new value of the shadowed registers, if updated, takes effect on the next **RSZ\_INT\_REG** event. Then again, shadowed registers can be updated for the next frame after the **RSZ\_INT\_REG** event is triggered. This event is active high for one GCK\_MMR clock cycle.

The interrupts are enabled from the **ISP5\_IRQENABLE\_SET\_i** register (where  $i = 0$  to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

### 8.3.2.7 ISS ISP H3A Integration

#### 8.3.2.7.1 ISS ISP H3A Interrupts

H3A can generate the following interrupts:

- **H3A\_INT**: This event is triggered at the end of the last window or last pixel, whichever completes last. This always triggers at the same time as **H3A\_INT\_EOF**.
- **H3A\_INT\_EOF**: This event is triggered and generated at the end of the last window. This event is active high for one GCK\_MMR clock cycle.
- **H3A\_OVF**: This interrupt is generated when an overflow happens in the H3A output buffer. The interrupt avoids polling the **H3A\_PCR[21]** OVF bit for errors. Overflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level. The event is active high for one GCK\_MMR clock cycle.

The interrupts are enabled from **ISP5\_IRQENABLE\_SET\_i** and **ISP5\_IRQENABLE\_SET2\_i** (where  $i = 0$  to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

### 8.3.2.8 ISS ISP ISIF Integration

#### 8.3.2.8.1 ISS ISP ISIF Interrupts

The ISIF can generate several interrupts:

- **ISIF\_INT\_0**: This event is triggered when the VD0 interrupt on line 0 is configured. The VD0 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in **VDINT0**. See [Section 8.3.3.7.19.1](#) for more information.

- ISIF\_INT\_1: This event is triggered when the VD1 interrupt on line 1 is configured. The VD1 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT1. See [Section 8.3.3.7.19.1](#) for more information.
- ISIF\_INT\_2: This event is triggered when the VD2 interrupt on line 2 is configured. The VD2 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT2. See [Section 8.3.3.7.19.1](#) for more information.
- ISIF\_INT\_3: This event is triggered LSC interrupt is an interrupt issued by the 2D-LSC block. See [Section 8.3.3.7.10.1.5](#) for more information.
- ISIF\_OVF: This Interrupt is generated when an overflow happens in the ISIF module. The interrupt avoids polling the [ISIF\\_MODESET\[11\]](#) OVF bit for errors.

The interrupts are enabled from the [ISP5\\_IRQENABLE\\_SET\\_i](#) and [ISP5\\_IRQENABLE\\_SET2\\_i](#) registers (where  $i = 0$  to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from ISP is sent to the ISS top level where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2](#), *ISP Top-Level integration*.

### 8.3.2.9 ISS ISP BL Integration

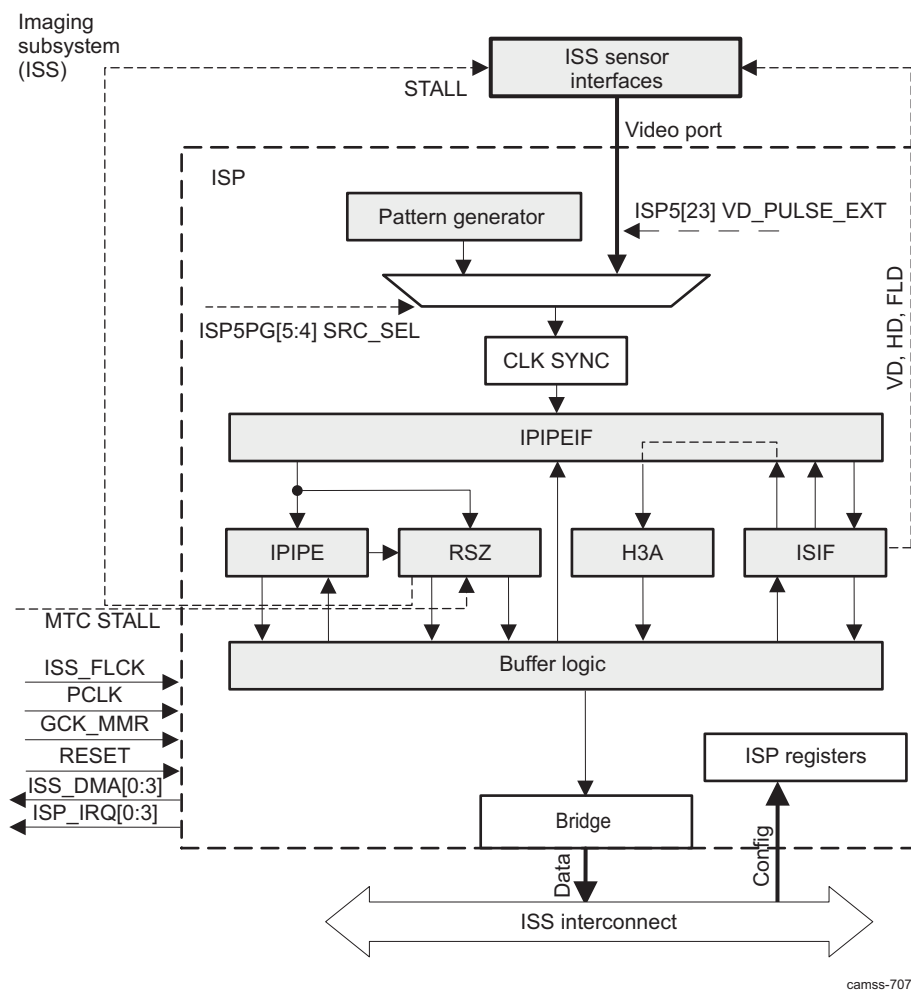

See [Section 8.3.2](#), *ISS ISP Integration*.

### 8.3.3 ISS ISP Functional Description

The functionality of the ISP is part of the overall performance of the ISS. For the top-level ISS diagram with ISP inside and for a features list, see [Section 8.1, ISS Overview](#). [Figure 8-108](#) is an overview of the ISP module. It outputs DMA and interrupt requests, has clocks coming in, and a stall signal to the CCP2 interface receiver from the resizer. It also shows the top-level configuration for input to IPIPEIF. For the scaled-in functional details of each submodule inside the ISP, see its functional description section.

**Figure 8-108. ISS ISP High-Level Diagram**

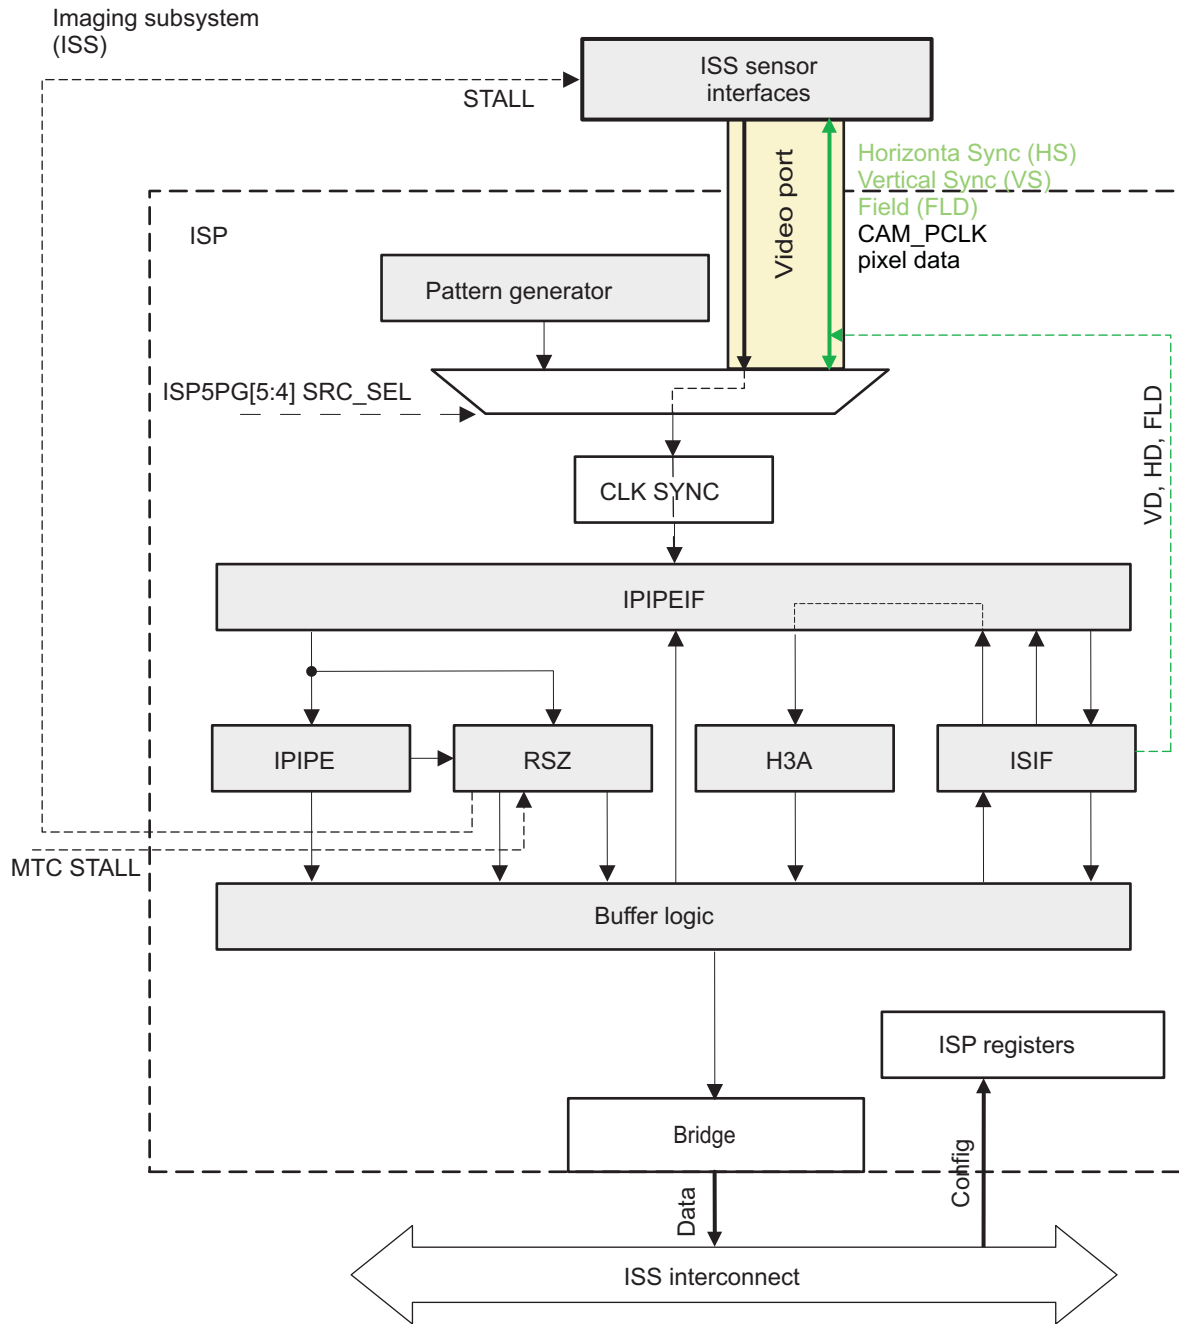

#### 8.3.3.1 ISS ISP VP Functional Description

##### 8.3.3.1.1 ISS ISP VP Overview

The VP supports a parallel interface that is used for interfacing with image sensors. The ISP VP can transport 8- to 16-bit RAW data and 8-/16-bit YCbCr data.

[Figure 8-109](#) shows the VP module connections to other submodules of the ISP.

Figure 8-109. ISS ISP VP High-Level Diagram

camss-699

### 8.3.3.1.2 ISS ISP VP Data Formats

The VP can be used to connect external camera receivers to the ISS. Data paths inside the ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG, etc.). [Table 8-312](#) shows how the CCP2/CSI2 modules are connected to the VP in function of the image format.

**Table 8-312. ISS ISP VP Format Mapping**

### 8.3.3.1.3 ISS ISP VP Top-Level Communication With CCP2 RX and CSI2 RX

At the ISS level, the VP is connected to the VP of the CCP2 RX and CSI2 RX modules. The interface that the VP uses to connect to the ISP is selected at the top-level of the ISS through the ISS\_CTRL[3:2] INPUT\_SEL bit. VP implementation differences force the introduction of a bridge between the CCP2 RX/CIS2 RX modules and the VP. The role of the bridge is to perform VD pulse extension. The CCP2 RX module assumes that the VD signal is active for at least one pixel clock cycle, and the CSI2 RX module assumes that the VD signal is asserted for four pixel clock cycles. However, the ISP assumes that the VD pulse is active on at least one line.

Figure 8-110 shows how the VD pulse extension works. Assume that VD-IN is the VD signal at the input of the pulse extension bridge, and VD-OUT is the VD signal at the output of the pulse extension bridge.

The VD-OUT signal is asserted at the same time as VD-IN. The VD-OUT signal is kept high until one full line is received. A line is delimited by two rising edges of the HD signal. The VD-OUT pulse is deasserted on the next cycle after the falling edge of the HD signal.

Figure 8-110. ISS ISP VP VD Pulse

camss-691

The ISP5\_CTRL[23] VD\_PULSE\_EXT bit controls whether the VD extension bridge is enabled or disabled. By default, the bridge is enabled. When the bridge is disabled, the VD pulse must be unmodified: VD-OUT = VD-IN. At the ISS level, it is expected that ISP5\_CTRL [23] VD\_PULSE\_EXT = 1 when the VP gets data from the CSI2 RX modules and ISP5\_CTRL[23] VD\_PULSE\_EXT = 0 when the VP gets data from the parallel interface or CCP2 RX module.

**CAUTION**

A minimum of four lines per frame is required on the VP when the VD pulse extension bridge is enabled; therefore, the VD extension bridge is not functional if a 1-/2-/3-line frame is sent to the VP.

### 8.3.3.1.4 ISS ISP VP Pixel Clock Inversion

The ISP always uses the rising edge of the pixel clock to sample the pixel data. The ISP provides the capability to invert the pixel clock so it can shift the resampling of a pixel clock period by half. This is controlled by the ISP5\_CTRL[22] PCLK\_INV bit. By default, the inversion is disabled. The 5 bits in Table 8-313 are resynchronized from the GCK\_MMR clock domain to the PCLK clock domain. There must be at least three clock cycles between the time these bits are modified and the HD/VD pulse for start of frame comes.

**Table 8-313. ISS ISP VP GCK\_MMR to PCLK Clock Resynchronization**

Module	Register	Bit Field
ISP	<a href="#">ISP5_CTRL</a>	VD_PULSE_EXT
ISIF	<a href="#">ISIF_MODESET</a>	HDVDD
ISIF	<a href="#">ISIF_MODESET</a>	FIDD
ISP	<a href="#">ISP5_CTRL</a>	ISIF_CLK_ENABLE

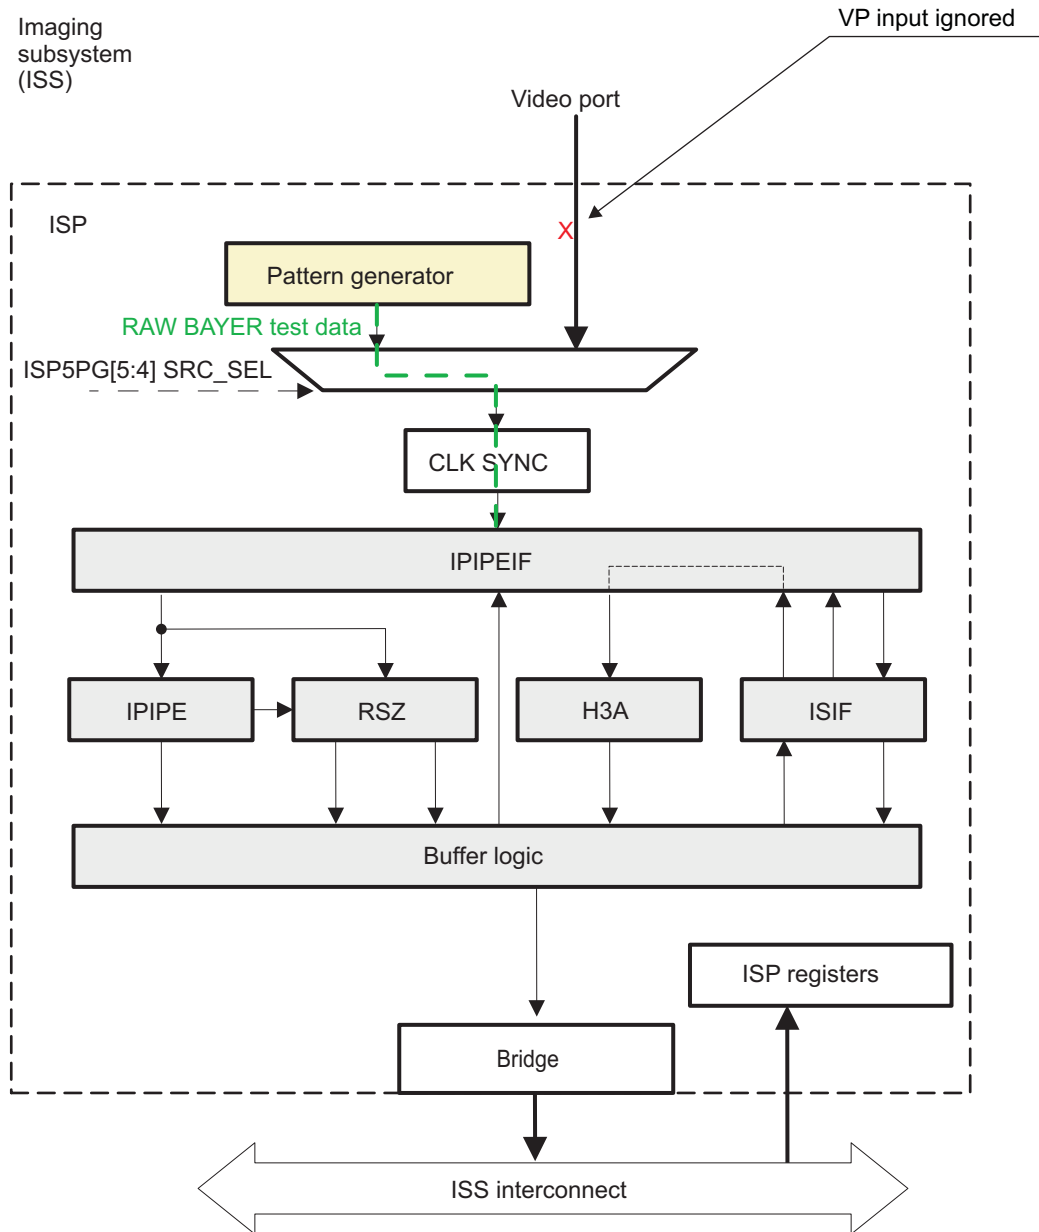

### 8.3.3.2 ISS ISP PG Functional Description

#### 8.3.3.2.1 ISS ISP PG Overview

The PG implements an internal data generation mechanism to test the external pins and can generate RAW data (to the IPIPEIF, ISIF, and other ISP modules) without the need for an external image sensor.

[Figure 8-111](#) show the PG module connections to other submodules of the ISP.

Figure 8-111. ISS ISP PG High-Level Diagram

camss-686

8.3.3.2.2 ISS ISP PG Functional Description

The data pattern is as follows:

- Data remain unchanged from frame to frame.
- Data are always generated as a BAYER pattern with RED (only on even/even pixel/line; other locations are RED = 0), GREEN (only on odd/even pixel/line and even/odd pixel/line; other locations are GREEN = 0) and BLUE (only on odd/odd pixel/line; other locations are BLUE = 0) colors.
- The frame is divided into four equal horizontal sections:
  - 1st horizontal section is further divided into eight equal vertical sections
    - 1st vertical section is RED only with maximum value (depending on number of bits programmed).
    - 2nd vertical section is RED and GREEN with maximum value.

- 3rd vertical section is RED, GREEN, and BLUE with maximum value.
- 4th vertical section RED and BLUE with maximum value.
- 5th vertical section is all zeros.
- 6th vertical section is GREEN and BLUE with maximum value.
- 7th vertical section is GREEN with maximum value.
- 8th vertical section is BLUE with maximum value.
- 2nd horizontal section is all RED with the pixel value linearly incrementing (reset to zero for each line) from zero onward.
- 3rd horizontal section is all GREEN with the pixel value linearly incrementing (reset to zero for each line) from zero onward.
- 4th horizontal section is all BLUE with the pixel value linearly incrementing (reset to zero for each line) from zero onward.

By default, the ISP source is the VP. To select PG as the source for the ISP, set the [ISP5\\_PG\[5:4\] SRC\\_SEL](#) bit field to 0x3.

The [ISP5\\_PG\[2\] WEN](#) bit controls write-enable signal generation for the PG module. There are two modes: the write enable signal is enabled all the time or it is enabled and disabled every eight clock cycles. The [ISP5\\_PG\[1\] HDPOL](#) and [ISP5\\_PG\[0\] VDPOL](#) bits control the polarity of the horizontal and vertical synchronization signals generated by the PG module. These signals can be active high or active low.

The [ISP5\\_PG\\_PULSE\\_CTRL](#) register controls the HS and VS signal widths for the PG module.

- The [ISP5\\_PG\\_PULSE\\_CTRL\[12:0\] HDW](#) bit field sets the duration of the HD signal in terms of pixel clock cycles. The actual duration of the signal is [ISP5\\_PG\\_PULSE\\_CTRL\[12:0\] HDW](#) + 1 cycle. The minimum signal duration is one cycle, and the maximum signal duration is 4096 cycles.
- The [ISP5\\_PG\\_PULSE\\_CTRL\[27:16\] VDW](#) bit field sets the duration of the VD signal in terms of lines. The actual duration of the signal is [ISP5\\_PG\\_PULSE\\_CTRL\[27:16\] VDW](#) + 1 line. The minimum signal duration is one line, and the maximum signal duration is 4096 lines.

The [ISP5\\_PG\\_FRAME\\_SIZE](#) register controls the PG module horizontal and vertical frame sizes.

- The [ISP5\\_PG\\_FRAME\\_SIZE\[31:16\] PPLN](#) bit field sets the number of pixels per line a frame generated by the PG module. The actual number of pixels in a line is set by [ISP5\\_PG\\_FRAME\\_SIZE\[31:16\] FRAME\\_PPLN](#) + 1. The minimum number of pixels is 1.
- [ISP5\\_PG\\_FRAME\\_SIZE\[15:0\] HLPFR](#) sets the number of lines per frame generated by the PG module. The actual number lines is set by [ISP5\\_PG\\_FRAME\\_SIZE\[15:0\] HLPFR](#) + 1. The minimum number of lines is one.

The [ISP5\\_PG\[3\] EN](#) bit enables or disables the PG module.

### 8.3.3.3 ISS ISP IPIPEIF Functional Description

#### 8.3.3.3.1 ISS ISP IPIPEIF Overview

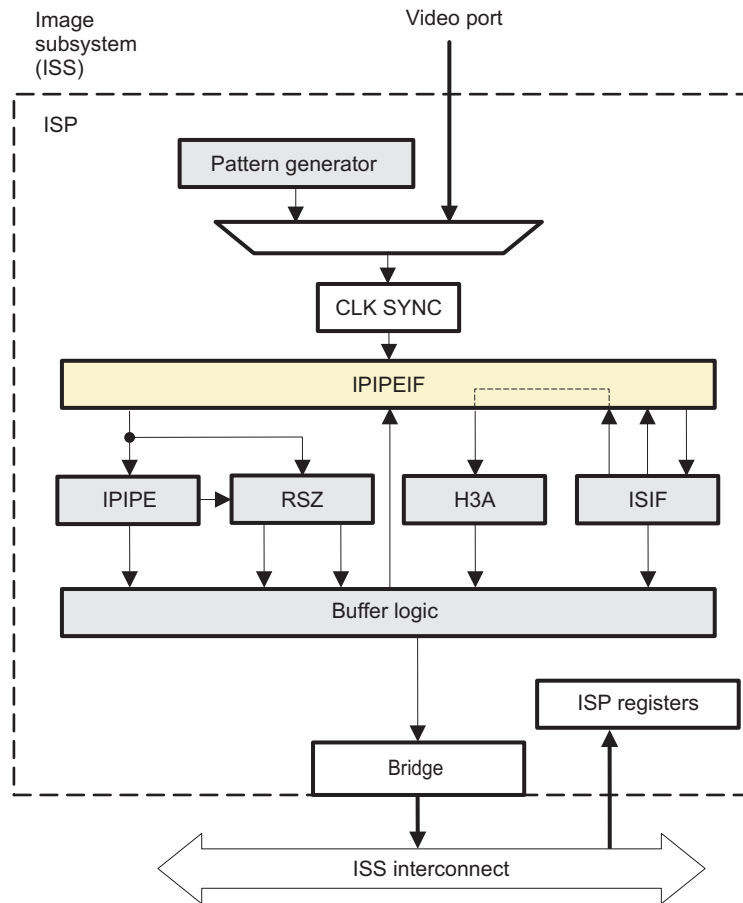

The IPIPEIF module provides data and synchronization signals (HD, VD) for the ISIF, IPIPE, RSZ, and H3A modules. The data source of this module is the VP, ISIF, or SDRAM using BL, and the selected data is output to ISIF, IPIPE, H3A, and RSZ. This module supports:

- Up to 16-bpp data on the VP
- Up to 200-MHz pixel clock on the VP, up to 8K × 8K imaging resolution
- RAW and YUV data formats on the VP and BL ports
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from VP
- Dark-frame subtract of 8-bit RAW image stored in SDRAM from image from ISIF
- Dark-frame subtract of 8-bit RAW image from VP from image read from SDRAM through the BL
- Simple defect correction to prevent the subtraction of defect pixels
- 8-10, 8-12 DPCM of 10-8, 12-8 DPCM compressed data in SDRAM

- Simple and advanced DPCM predictor
- Inverse A-Law decompression of RAW data 10-8 A-Law compressed from SDRAM
- 8-bit, 12-bit unpacking of 8-bit,12-bit packed SDRAM data
- Gain multiply for output data to IPIPE module
- Horizontal Bayer rescaler in the data paths to the IPIPE and H3A modules: Supports (1, 2, 1) averager filter and supports horizontal pixel decimation
- Data rate control when reading data from SDRAM: Fraction clock divider
- (1, 2, 1) averager filter and supports horizontal pixel decimation in the data path to the IPIPE for YUV data.

Figure 8-112 show the IPIPEIF module connections to other submodules of the ISP.

**Figure 8-112. ISS ISP IPIPEIF High-Level Diagram**

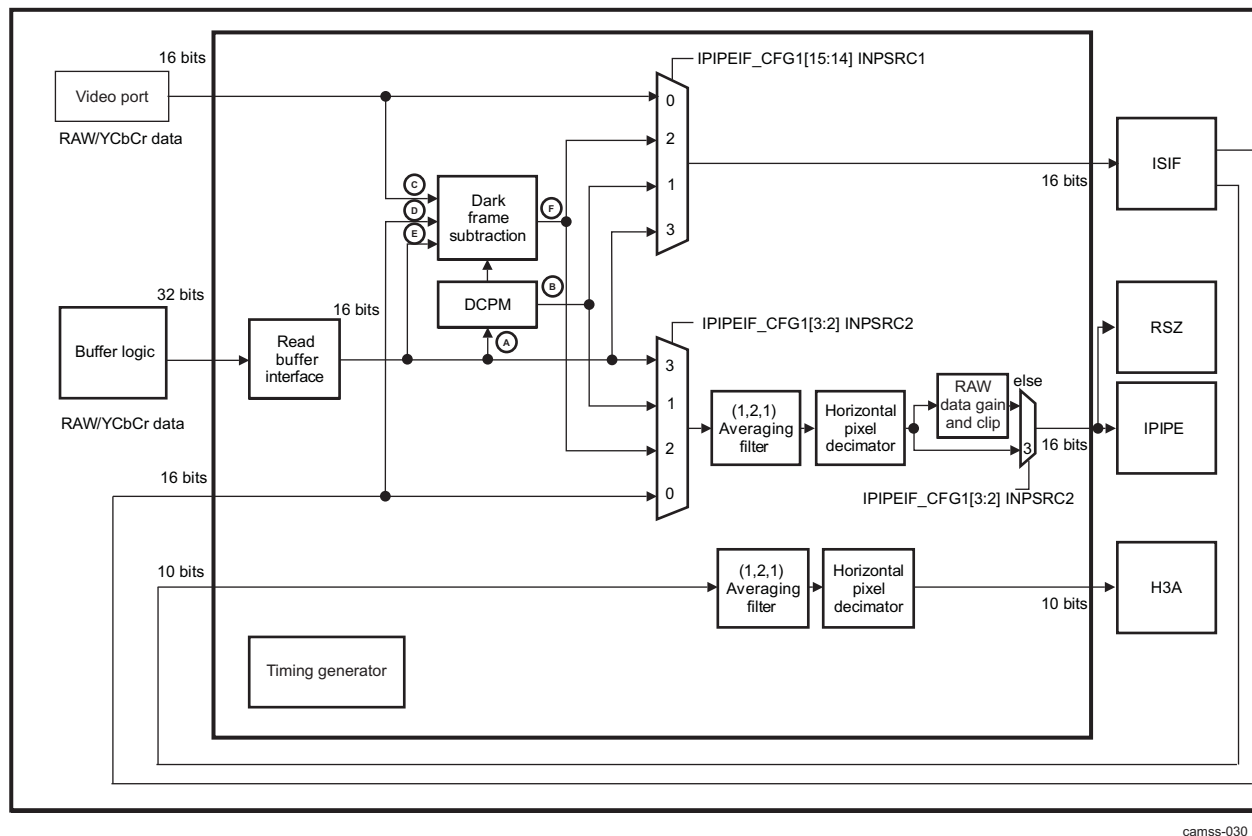

camss-003e

### 8.3.3.3.2 ISS ISP IPIPEIF Top-Level Block Diagram

The following sections describe the function of each subblock in the IPIPEIF, as shown in Figure 8-113.

Figure 8-113. ISS ISP IPIPEIF Top-Level Block Diagram

**NOTE:** When the IPIPEIF receives data from the VP, the timing generator must be configured for HD, VD, and WEN. For more information, see [Section 8.3.3.3.5, ISS ISP IPIPEIF Timing Generation](#).

### 8.3.3.3.3 ISS ISP IPIPEIF Input Interface

The IPIPEIF module comprises two major interface blocks: VP and BL. The data types can be RAW or YUV.

#### 8.3.3.3.3.1 ISS ISP IPIPEIF Input From VP

The VP typically receives data from the image sensor. At the ISS level, it is connected to the serial interface receivers.

#### 8.3.3.3.3.2 ISS ISP IPIPEIF Input From BL

The BL is the interface with the memory (SDRAM). In that case, the SDRAM address and line offset registers must be programmed in units of 32 bytes.

- SDRAM start address (byte) =  $(\text{IPPIPEIF\_ADDRU}[10:0] \text{ ADDRU}) \ll 16 + (\text{IPPIPEIF\_ADDRL}[15:0] \text{ ADDR L})$
- SDRAM address offset (byte) =  $\text{IPPIPEIF\_ADOFS}[11:0] \text{ ADOFS}$

Two types of data can be stored in memory: pixel data and dark frame data.

For pixel data, the HD and VD signals are reconstructed with:

- [IPPIPEIF\\_HNUM](#)
- [IPPIPEIF\\_VNUM](#)

- IPIPEIF\_LPFR
- IPIPEIF\_PPLN

The IPIPEIF\_HNUM and IPIPEIF\_VNUM registers define the number of pixels per line and lines per frame to read from the SDRAM, and the IPIPEIF\_LPFR and IPIPEIF\_PPLN registers define the interval of VD and HD, respectively.

Vertical blanking for the frame is defined with the following equation:  $IPIPEIF\_LPFR - IPIPEIF\_VNUM - 1$ .

Horizontal blanking for the frame should be at least eight ISS\_FCLK cycles, and is defined with the following equation:  $IPIPEIF\_PPLN - IPIPEIF\_HNUM > 7$ .

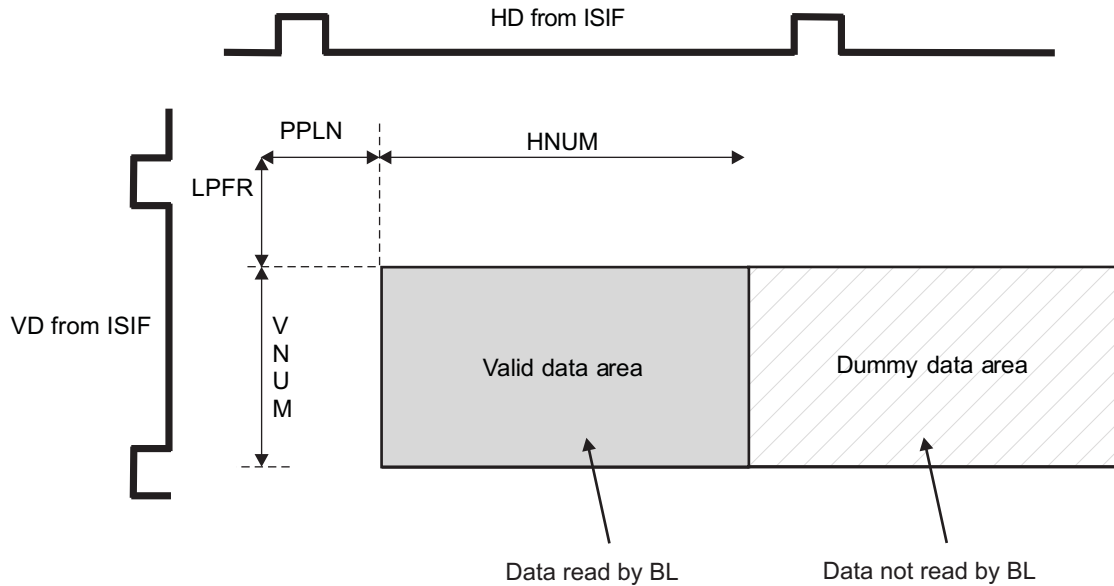

Figure 8-114 shows the global frame definition for all SDRAM input modes, except for dark frame subtract.

**Figure 8-114. ISS ISP IPIPEIF Global Frame Definition in SDRAM Input Modes (Except Dark Frame)**

camss-031

For dark frame data, the HD and VD signals come from the VP through the ISIF. The IPIPEIF\_PPLN and IPIPEIF\_LPFR registers must be used to indicate the horizontal and vertical start position of the subtraction from the ISIF data, as shown in Figure 8-115. The value of the IPIPEIF\_LPFR [12:0] LPFR bit field must be greater than 0 because the first line from the VP or ISIF cannot be subtracted from. The IPIPEIF\_HNUM and IPIPEIF\_VNUM registers must be used to set the number of valid pixels horizontally and the number of valid lines vertically.

**Figure 8-115. ISS ISP IPIPEIF Global Frame Definition in Dark Frame Subtract Mode**

camss-034

#### 8.3.3.3.2.1 ISS ISP IPIPEIF Double-Buffer Input Function When Reading From BL

The IPIPEIF module supports a double-buffer input function. This feature is most useful when SDRAM space is limited, because it enables to read continuously from two buffers and to push data to the rest of the ISP (ISIF, H3A, etc.) for further processing.

Consider the following configuration where data are read from two buffers, A and B. The intent is not only to read continuously from these buffers but also to ensure that the ISP modules consider the data as being from the same frame; that is, VD is generated the first time buffer A is read, but it must not toggle until all the frames are read.

The IPIPEIF module can mask the VD sync signal by writing the `IPIPEIF_ENABLE[1] SYNCOFF` bit but such that the IPIPEIF module drives the data to the ISP modules as if it is a continuous frame data.

In the following example, there are 16 lines per trigger and input circular addressing.  $VNUM = 16$  (see [Figure 8-114](#)), and the VD signal is generated only for the first frame (see [Figure 8-116](#)).

Figure 8-116. ISS ISP IPIPEIF Double-Buffer Functionality

camss-615

8.3.3.3.4 ISS ISP IPIPEIF Data Path Selection

The data path configuration through the IPIPEIF module is set with the IPIPEIF\_CFG1[15:14] INPSRC1 and IPIPEIF\_CFG1[3:2] INPSRC2 bit fields. Table 8-314 lists the possible combinations for these two bit fields.

Table 8-314. ISS ISP IPIPEIF IPIPEIF\_CFG1[15:14] INPSRC1 and IPIPEIF\_CFG1[3:2] INPSRC2 Possible Combinations

IPIPEIF_CFG1[15:14] INPSRC1	IPIPEIF_CFG1[3:2] INPSRC2	Description	Common Use
0	0	This data path is described in Section 8.3.3.3.4.1, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0.	Video record, view finder, on-the-fly still image capture applications
0	1	This data path is described in Section 8.3.3.3.4.2, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1.	Memory-to IPIPE-to memory
0	2	This data path is described in Section 8.3.3.3.4.3, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2.	Image capture with on-the-fly dark frame subtraction

**Table 8-314. ISS ISP IPIPEIF IPIPEIF\_CFG1[15:14] INPSRC1 and IPIPEIF\_CFG1[3:2] INPSRC2 Possible Combinations (continued)**

<b>IPIPEIF_CFG1[15:14] INPSRC1</b>	<b>IPIPEIF_CFG1[3:2] INPSRC2</b>	<b>Description</b>	<b>Common Use</b>
0	3	This data path is described in <a href="#">Section 8.3.3.3.4.4</a> , <i>ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3</i> .	On-the-fly data acquisition done in VP, forwarded to the ISIF, and then to the H3A through IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory YUV4:2:2 or RAW data processing with the IPIPE and RESIZER modules from memory to memory fetched by IPIPEIF
1	0	This data path is described in <a href="#">Section 8.3.3.3.4.5</a> , <i>ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0</i> .	Memory-to-ISIF- to memory operation

2	2	This data path is not supported.	N/A
2	3	This data path is not supported.	N/A
3	0	This data path is described in <a href="#">Section 8.3.3.3.4.7</a> , <i>ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0</i> .	Memory-to-ISIF-to memory operation
3	1	This data path is not supported.	N/A
3	2	This data path is not supported.	N/A
3	3	This data path is possible but there is no use case associated.	N/A

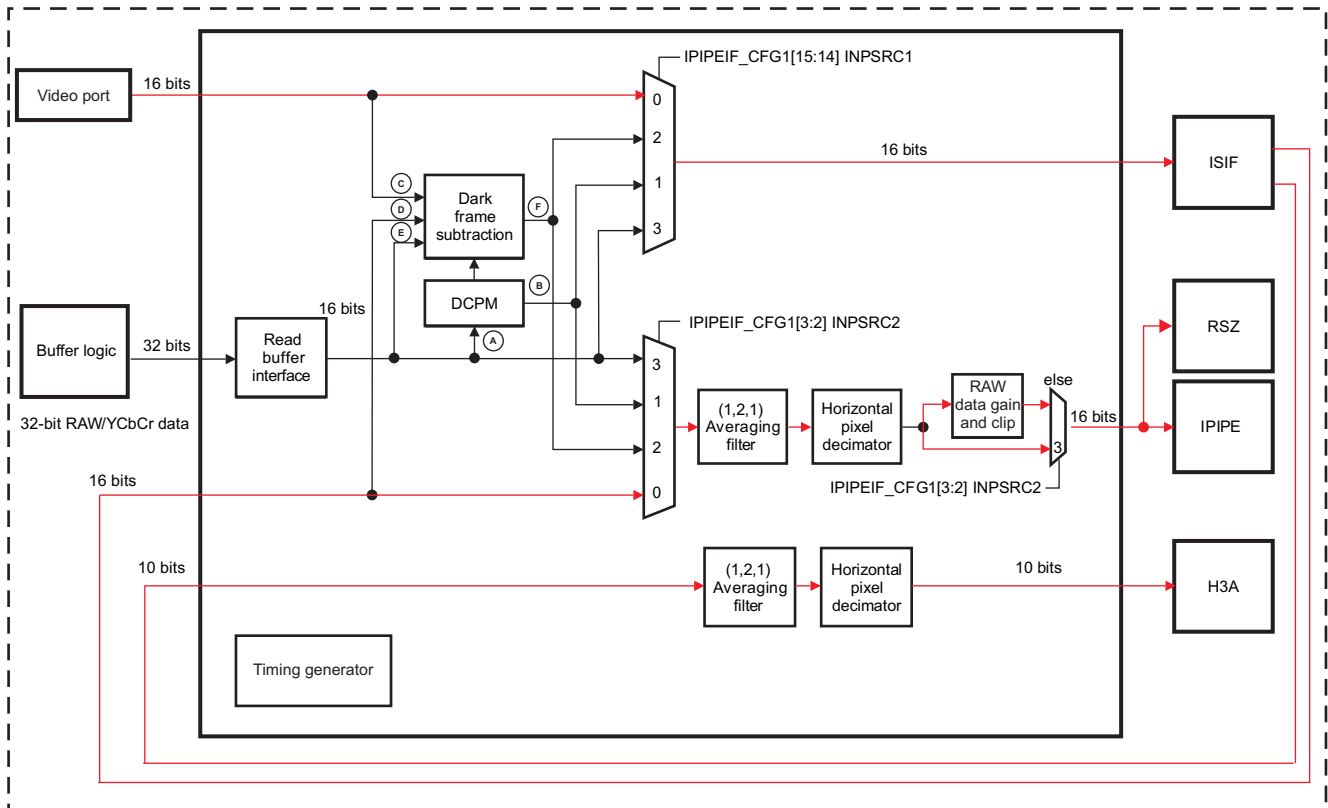

#### 8.3.3.3.4.1 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0

Set the [IPIPEIF\\_CFG1\[15:14\] INPSRC1](#) bit field to 0 and the [IPIPEIF\\_CFG1\[3:2\] INPSRC2](#) bit field to 0.

This configuration can be used for the video record, viewfinder, and on-the-fly still image capture applications. The full ISP processing capability is used in a single pass.

[Figure 8-117](#) shows the data path.

Figure 8-117. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0 Data Path

camss-603

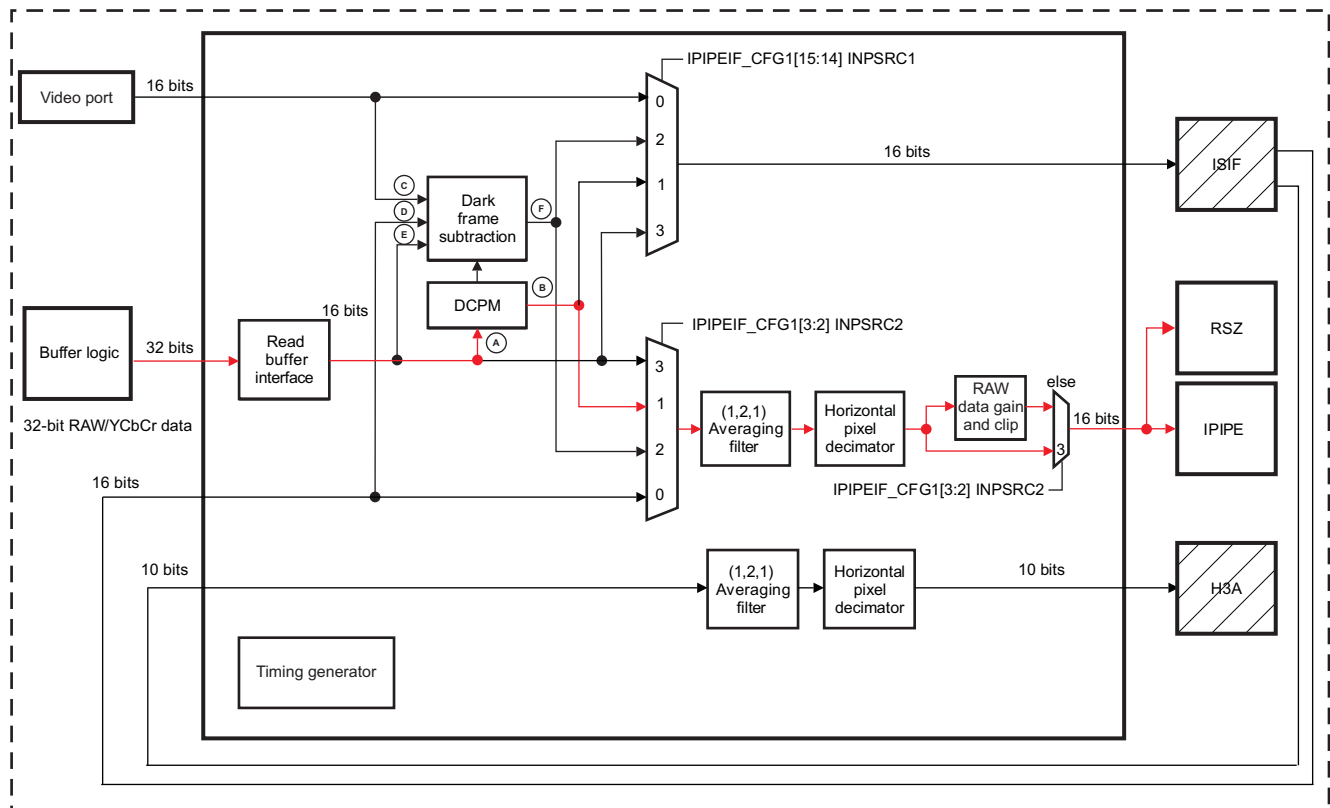

8.3.3.3.4.2 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1

Set the IPIPEIF\_CFG1[15:14] INPSRC1 bit field to 0 and the IPIPEIF\_CFG1[3:2] INPSRC2 bit field to 1.

This configuration can be used to process data with the IPIPE module from memory to memory. The data stored in SDRAM can be decompressed (A-law or DPCM) before being forwarded to the IPIPE module.

**NOTE:** In this configuration, the ISIF and H3A modules are assumed to be disabled.

Figure 8-118 shows the data path.

**Figure 8-118. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1 Data Path**

camss-604

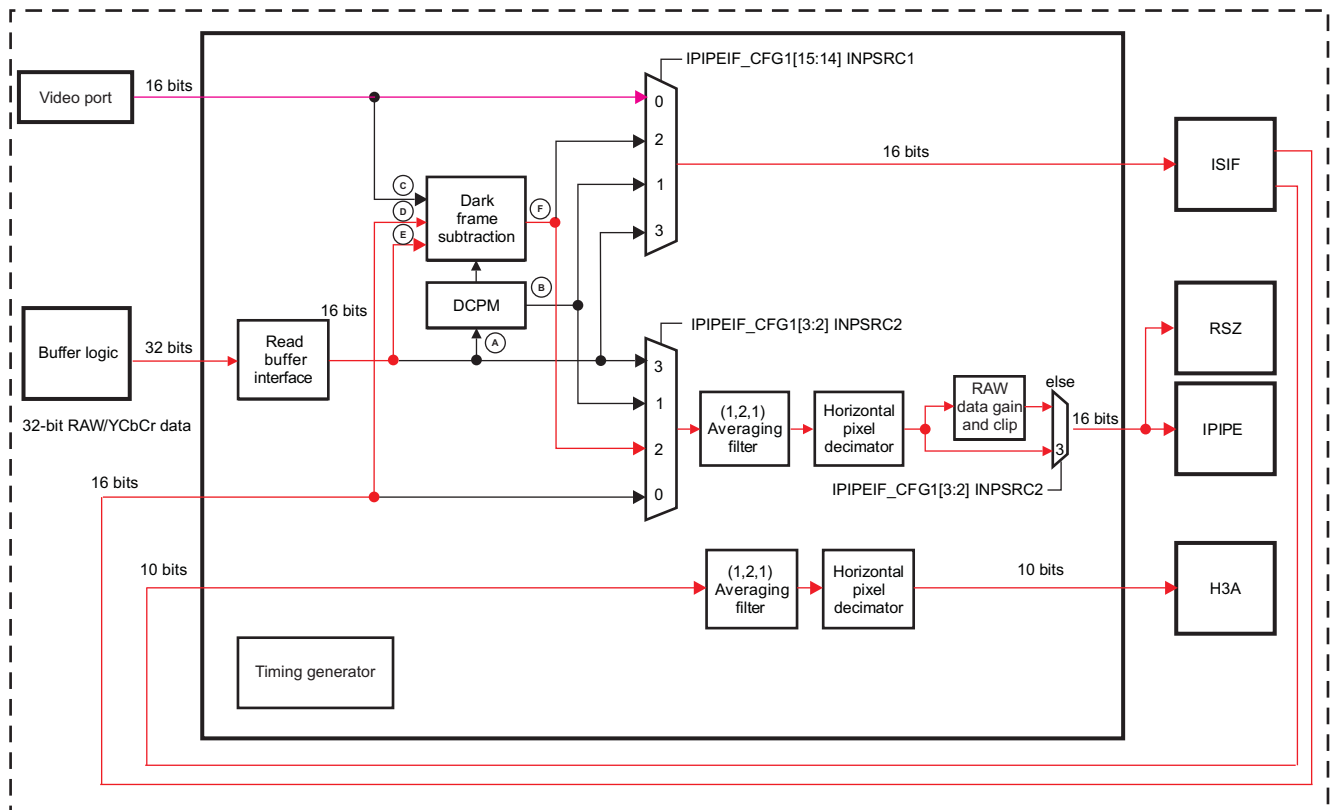

### 8.3.3.3.3 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2

Set `IPIPEIF_CFG1[15:14] INPSRC1` to 0 and `IPIPEIF_CFG1[3:2] INPSRC2` to 2.

This configuration can be used for image capture with on-the-fly dark-frame subtraction. In the first case, the dark frame can come from BL and data from the ISIF. In the second case, the dark frame can come from the VP and data from BL.

Figure 8-119 shows the data path.

Figure 8-119. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2 Data Paths

camss-610

#### 8.3.3.3.4.4 ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 0 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 3.

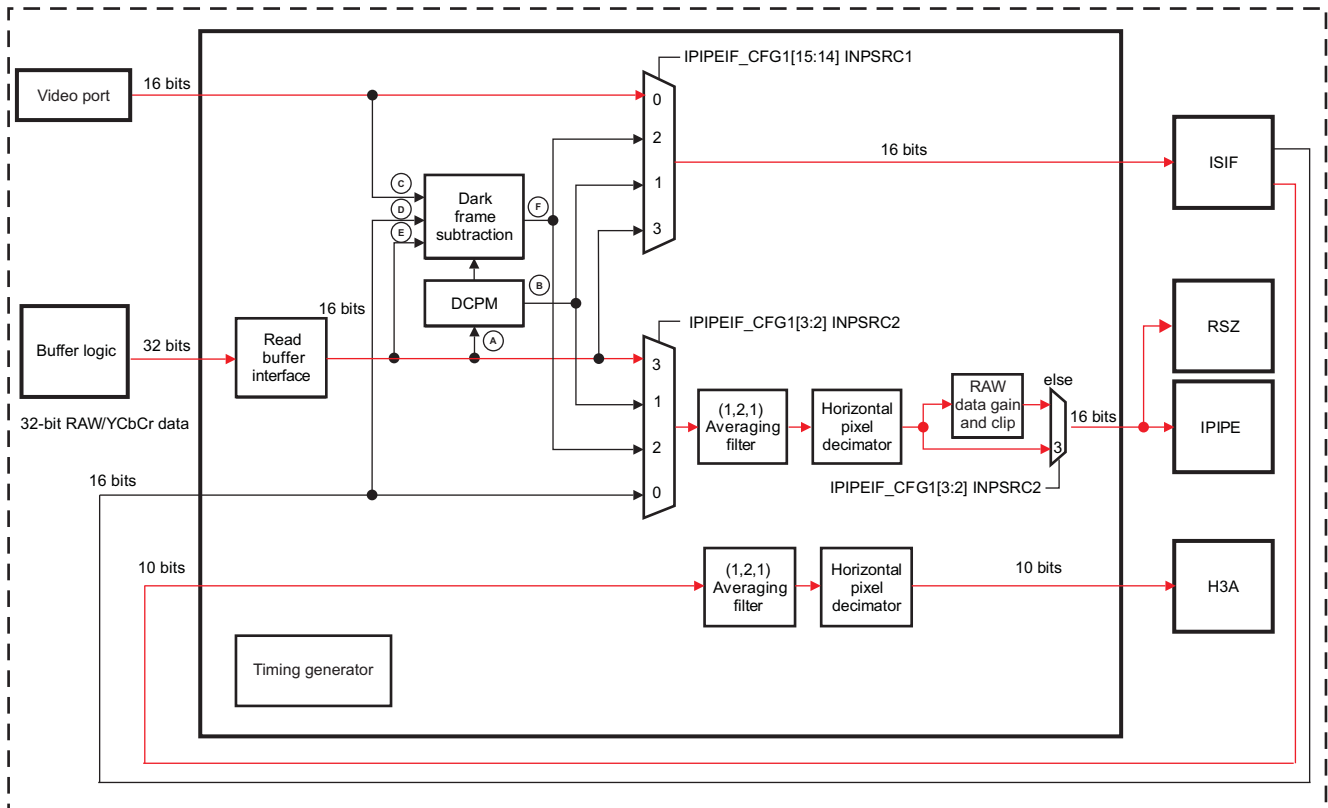

In the first case, on-the-fly data acquisition is done with the VP, forwarded to the ISIF, and then sent to the H3A through the IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory.

In the second case, the configuration can be used to process YUV4:2:2 or RAW data with the IPIPE and RESIZER modules from memory-to-memory. The YUV4:2:2 or RAW data stored in the SDRAM is fetched and forwarded to the IPIPE and RSZ modules. ISIF and H3A are assumed to be disabled in this configuration.

Figure 8-120 and Figure 8-121 show the two possible data paths.

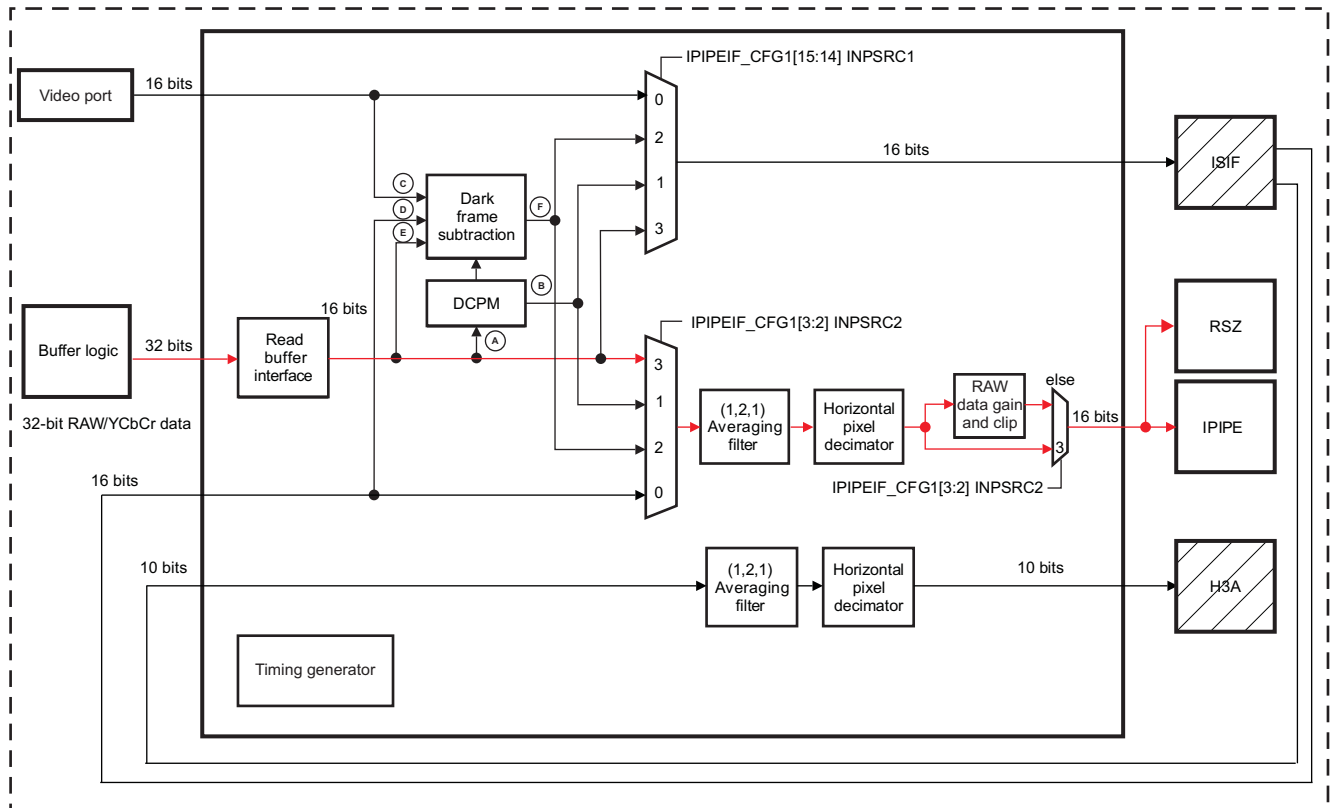

**Figure 8-120. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: First Case**

camss-606

Figure 8-121. ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3 Data Paths: Second Case

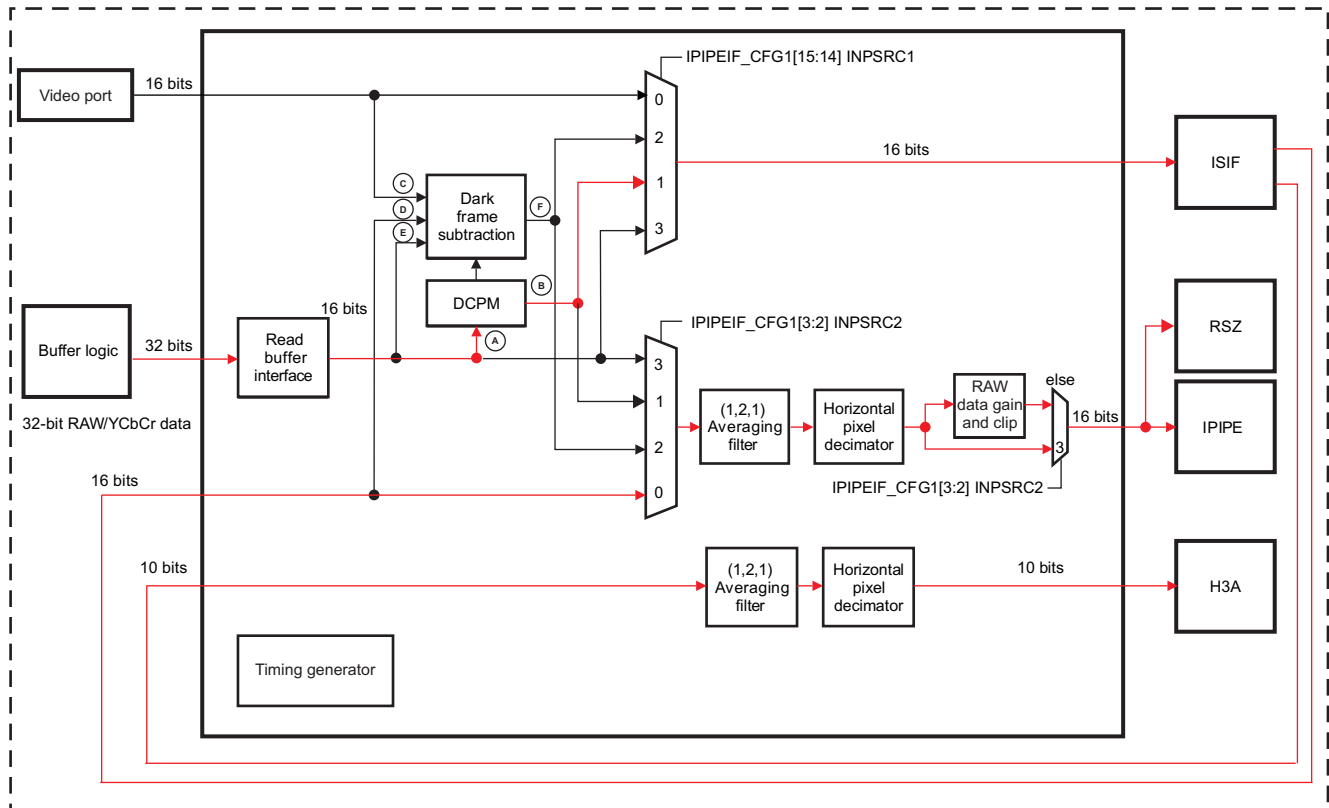

camss-605

8.3.3.3.4.5 ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 1 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 0.

This configuration is a memory-to-memory operation. RAW data is read by the BL interface, decompressed, and pushed to the ISIF. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE and H3A modules.

Figure 8-122 shows the data path.

**Figure 8-122. ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0 Data Path**

camss-607

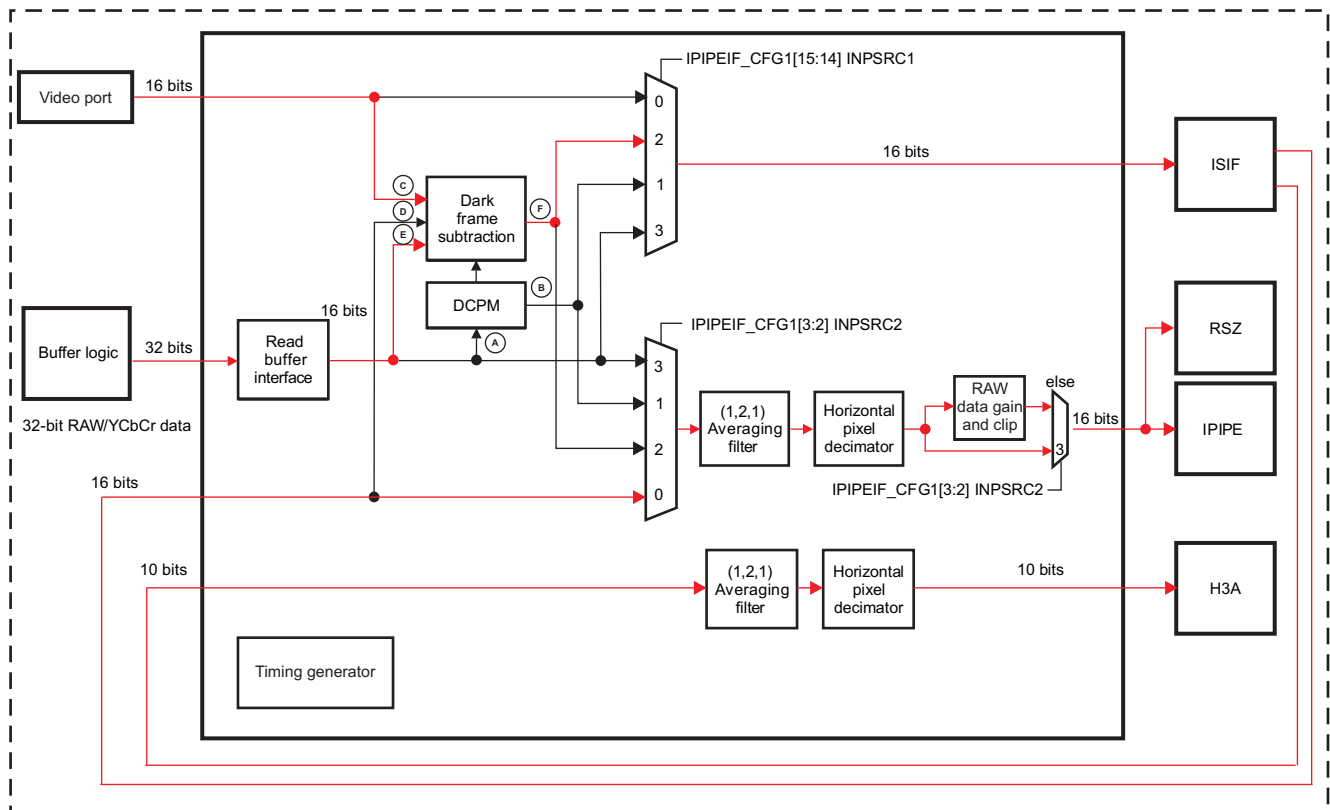

#### 8.3.3.3.4.6 ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 2 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 0.

In this configuration, dark frame subtraction is performed and data is sent to the ISIF module. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ modules. There are two possible dark frame subtractions: the first is with data coming from the VP and the dark frame coming from BL; the second is with data coming from BL and the dark frame coming from the VP.

Figure 8-123 shows the data path.

Figure 8-123. ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0 Data Path

camss-608

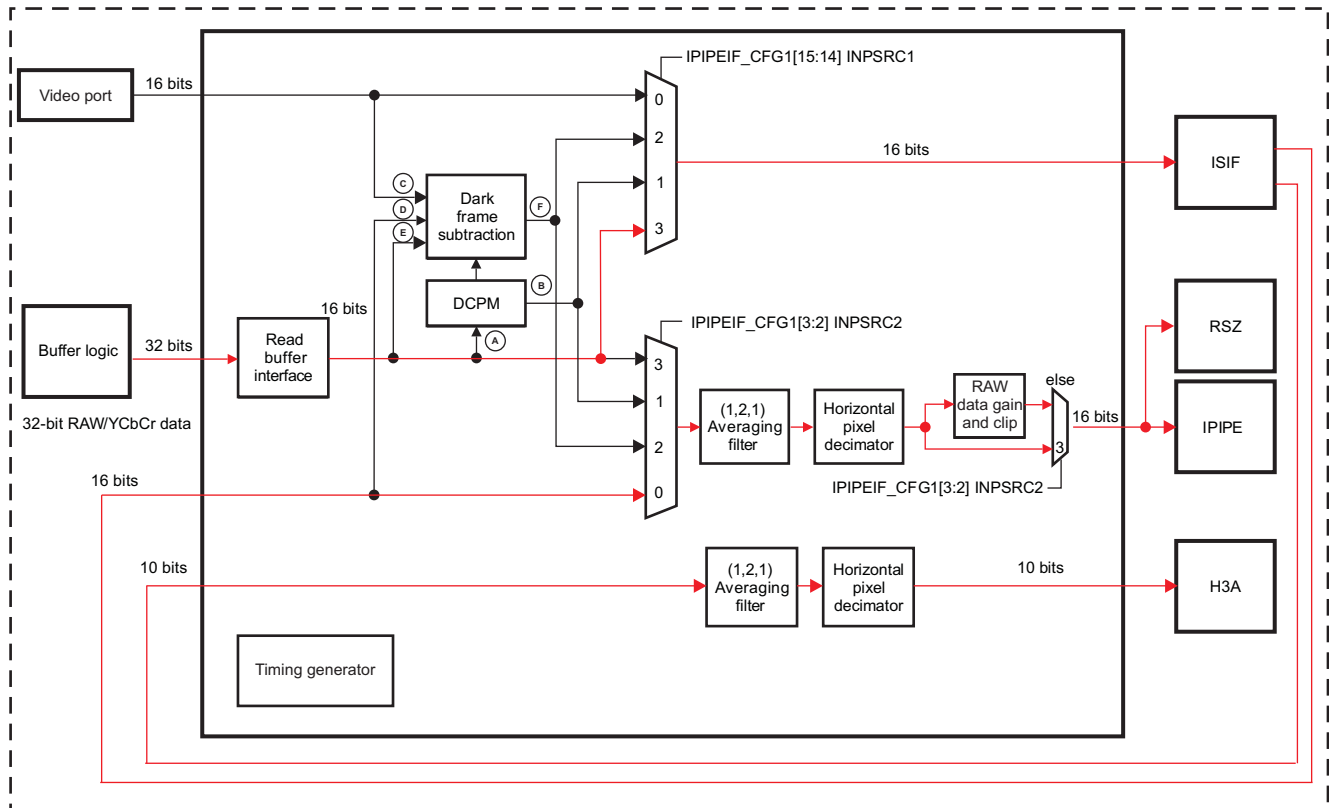

### 8.3.3.3.4.7 ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 3 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 0.

This configuration is a memory-to-memory operation. Data is loaded from the SDRAM. Input data is expected as 16 bpp. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ module.

In this configuration data is assumed to be YUV only, and H3A and RAW data gain are assumed to be disabled.

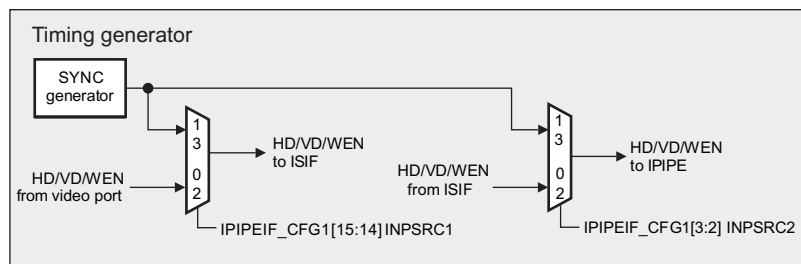

Figure 8-124 shows the data path.

**Figure 8-124. ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0 Data Path**

camss-609

### 8.3.3.3.5 ISS ISP IPIPEIF Timing Generation

Figure 8-125 shows the ISS ISP IPIPEIF timing generator submodule.

**Figure 8-125. ISS ISP IPIPEIF Timing Generator Submodule**

camss-602

When the IPIPEIF module input source is from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 0 or 2`) or the ISIF (`IPIPEIF_CFG1[3:2] INPSRC2 = 0 or 2`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 0 so that data is latched using the PCLK, HD, and VD signals from the VP.

When the IPIPEIF module input source is not from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 1 or 3`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 1 so that the IPIPEIF module generates its proper PCLK, HD, and VD signals (through the use of the SYNC generator). The `IPIPEIF_CLKDIV` register is then used to select a divide ratio of the SDRAM (DMA) clock for the pixel clock frequency, which is used to clock the data into the PCLK. See [Section 8.3.3.3.5.1, ISS ISP IPIPEIF Fractional Clock Divider](#).

When the `IPIPEIF_CFG1[15:14] INPSRC1` or `IPIPEIF_CFG1[3:2] INPSRC2` bit field is not set to 0, the IPIPEIF SDRAM data reading and timing generation can be enabled (`IPIPEIF_ENABLE[0] ENABLE`) in one-shot mode or continuous mode (`IPIPEIF_CFG1[0] ONESHOT`).

**8.3.3.3.5.1 ISS ISP IPIPEIF Fractional Clock Divider**

When the input data of the IPIPEIF module does not come from the VP but from memory, it is useful to have control of the rate at which the data is fetched from memory to avoid overflow conditions or to avoid peak bandwidth requirements. The IPIPEIF\_CFG1[10] CLKSEL bit is equal to 1 for fractional divider use.

The ISP clock ISS\_FCLK is divided to generate the pixel clock, which goes to the ISIF and IPIPE modules when data is read from memory (IPIPEIF\_CFG1[15:14] INPSRC1 = IPIPEIF\_CFG1[3:2] INPSRC2 = 1 or 3). The IPIPEIF\_CLKDIV register selects the divider ratio: M and N values in the IPIPEIF\_CLKDIV[15:0] CLKDIV bit field.

Given an input clock of clock rate ISS\_FCLK, the fractional clock divider generates an output clock with average clock rate f\_out.

Where f\_out = ISS\_FCLK x M/N, and M = 1 through 256, and N = 1 through 256.

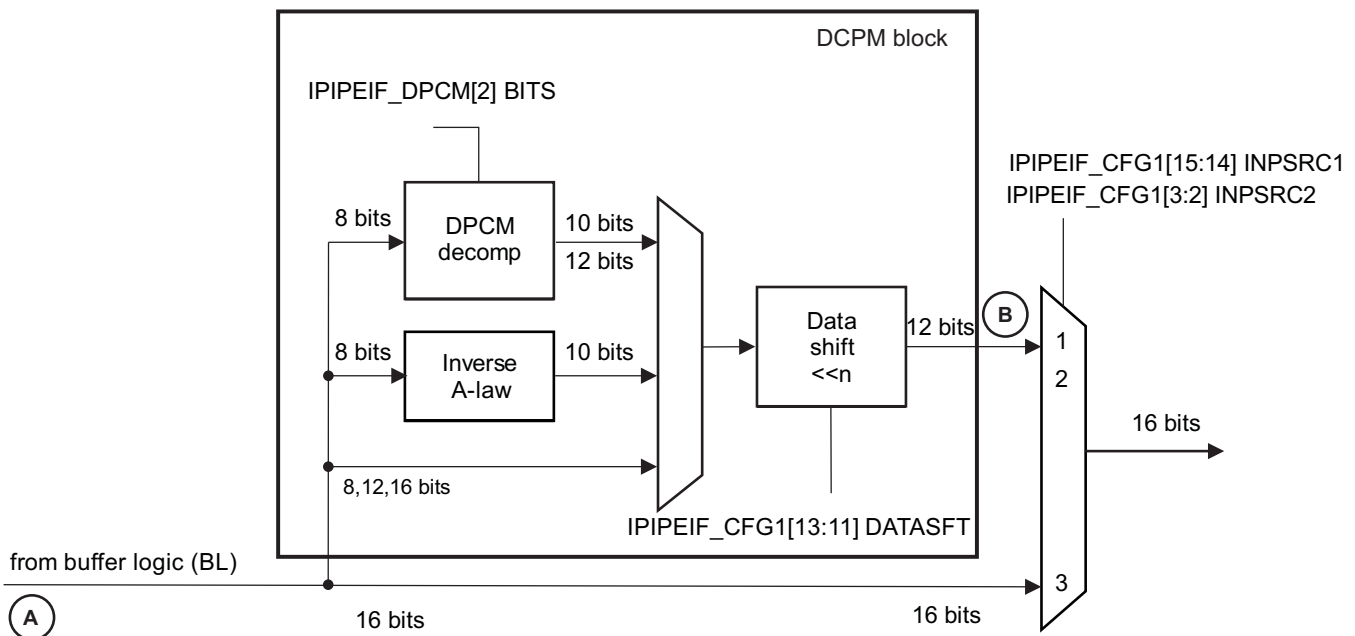

The fractional clock divider logic is synchronous and uses only the positive clock edge of the input clock.

**8.3.3.3.6 ISS ISP IPIPEIF Decompression (DCPM) Subblock: Unpack and Decompression Function**

The IPIPEIF module can read RAW data from memory. The RAW data can be previously packed/compressed into memory. Unpack, A-Law decompression, and DPCM decompression are available in the IPIPEIF module.

Figure 8-126 shows the DCPM subblock.

**Figure 8-126. ISS ISP IPIPEIF DCPM Subblock**

camss-032

Table 8-315 provides the possible configuration of the DCPM block.

**Table 8-315. ISS ISP IPIPEIF DCPM Block Possible Configuration**

Number of Bits per Pixel at DCPM Block Input	Number of Bits per Pixel at DCPM Block Output	Description	Registers
16	16	It can correspond to YUV4:2:2 or RAW16 data.	IPIPEIF_CFG1[9:8] UNPACK = 0x0 In this configuration, IPIPEIF_CFG1[3:2] INPSRC2 = 0x3. In this configuration data bypasses the DCPM block.

**Table 8-315. ISS ISP IPIPEIF DCPM Block Possible Configuration (continued)**

Number of Bits per Pixel at DCPM Block Input	Number of Bits per Pixel at DCPM Block Output	Description	Registers
8	8	PACK8: YUV	<a href="#">IPIPEIF_CFG1</a> [9:8] UNPACK = 0x1 <a href="#">IPIPEIF_DPCM</a> [0] ENA = 0x0 <a href="#">IPIPEIF_CFG1</a> [13:11] DATASFT = 0x01. In this configuration an 8-bit packed RAW data is used in DFS mode or YUV4:2:0 pass through. (See <a href="#">Section 8.3.3.3.13</a> , <i>ISS ISP IPIPEIF YUV4:2:2 8-bits Packed Data Input Coming From ISIF Module.</i> )
8	10	DPCM10: The 8-bit input data are DPCM-decompressed in 10 bits.	<a href="#">IPIPEIF_CFG1</a> [9:8] UNPACK = 0x1 <a href="#">IPIPEIF_DPCM</a> [0] ENA = 0x1 <a href="#">IPIPEIF_DPCM</a> [2] BITS= 0x0 Set the <a href="#">IPIPEIF_DPCM</a> [1] PRED <sup>(1) (2)</sup> <a href="#">IPIPEIF_CFG1</a> [13:11] DATASFT = 0x2
8	12	DPCM12: The 8-bit input data are DPCM-decompressed in 12 bits.	<a href="#">IPIPEIF_CFG1</a> [9:8] UNPACK = 0x1 <a href="#">IPIPEIF_DPCM</a> [0] ENA = 0x1 <a href="#">IPIPEIF_DPCM</a> [2] = 0x1 Set the <a href="#">IPIPEIF_DPCM</a> [1] PRED <sup>(1) (2)</sup> <a href="#">IPIPEIF_CFG1</a> [13:11] DATASFT = 0x0
8	10	ALAW10: The 8-bit input data were previously A-law compressed. The 8 bits are A-law decompressed and padded with 0.	<a href="#">IPIPEIF_CFG1</a> [9:8] UNPACK = 0x2 <a href="#">IPIPEIF_CFG1</a> [13:11] DATASFT = 0x2
12	12	PACK12: The input is coded on 12 bits and is packed in the SDRAM. This mode is compatible with the ISIF module packing capability. If inverse A-law and DPCM decompression are not enabled, the data read from the SDRAM can be shifted by the <a href="#">IPIPEIF_CFG1</a> [13:11] DATASFT bit field to select which 12 bits to use. MSB input data bit must be shifted such that it corresponds to bit 11 after the shift.	<a href="#">IPIPEIF_CFG1</a> [9:8] UNPACK = 0x3 Set the <a href="#">IPIPEIF_CFG1</a> [13:11] DATASFT

<sup>(1)</sup> The simple predictor uses only the value of the previous same color component as a prediction value. Therefore, only 2-pixel memory is required. It is typically used for 10–8–10 or 12–8–12 bit conversions.

<sup>(2)</sup> The advanced predictor uses four previous pixel values, when the prediction value is evaluated. This means that the values of the other color components are also used, when the prediction value is defined. Therefore, the advanced predictor is slightly better than the simple predictor but consumes more power and memory. It can, however, improve image quality. It is typically used for 10–7–10 and 10–6–10 bit conversions.

8.3.3.3.7 ISS ISP IPIPEIF Dark-Frame Subtraction Functionality

Figure 8-127. ISS ISP IPIPEIF Dark-Frame Subtraction Subblock

camss-033

The dark-frame subtract function is used to remove noise from the sensor. Typically, the ISIF module previously writes a dark frame (frame captured when the shutter is closed) to SDRAM using 8 bits of linear data packed into 2 pixels per 16 bits.

In this mode, RAW data from the ISIF and SDRAM is used. Data can also be read from SDRAM with the [IPIPEIF\\_CFG1\[9:8\] UNPACK](#) bit field set to 1. Each pixel read from SDRAM is subtracted from each pixel sent from the VP or ISIF.

The mux at the input of the dark-frame subtraction subblock is implicitly controlled by the selection of the [IPIPEIF\\_CFG1\[15:14\] INPSRC1](#) and [IPIPEIF\\_CFG1\[3:2\] INPSRC2](#) bit fields:

- When [IPIPEIF\\_CFG1\[15:14\] INPSRC1](#) = 0x2, the selected input ports are VP and BL. Therefore, the dark frame operation can be:
  - Dark frame = VP – BL
  - Dark frame = BL – VP
- When [IPIPEIF\\_CFG1\[3:2\] INPSRC2](#) = 0x2, the selected input ports are ISIF and BL. Therefore, the dark frame operation can be:
  - Dark frame = ISIF – BL
  - Dark frame = BL – ISIF

The output of the dark frame subtract operation is 12-bits wide (U12Q0). There must be adequate SDRAM bandwidth if this feature is enabled. If the data fetched from memory arrives late, an underflow bit ([IPIPEIF\\_DTUF](#)) must be triggered to know it .

8.3.3.3.7.1 ISS ISP IPIPEIF Defect Pixel Correction

**NOTE:** For DPC memory access locations, see [Section 8.3.3.9](#).

A simple DPC can be applied to the ISIF or VP input data path and SDRAM input data path, respectively. This DPC algorithm is intended to correct hot pixels during RAW dark frame acquisition or dark frame readout from SDRAM before dark frame subtraction.

The following code describes DPC algorithm:

```

If (image(n) < TH) || ((image(-2) > TH)&& (image(n+2) > TH))
    image(n) = image(n)
Else if image(-2) > TH
    image(n) = image(n+2)
Else if image(n+2) > TH
    image(n) = image(-2)
Else
    image(n) = (image(-2) + image(n+2)) / 2

// Where TH is equal to IPIPEIF_DPC1[11:0] TH for DPC1
// Where TH is equal to IPIPEIF_DPC2[11:0] TH for DPC2

```

The [IPIPEIF\\_DPC1\[12\]](#) ENA bit enables DPC for the VP/ISIF input path, and the [IPIPEIF\\_DPC2\[12\]](#) ENA bit enables DPC for the SDRAM input path. The algorithm requires a threshold value that is set by the [IPIPEIF\\_DPC1\[11:0\] TH](#) or [IPIPEIF\\_DPC2\[11:0\] TH](#) bit field that is a 12-bit unsigned value.

### 8.3.3.3.7.2 ISS ISP IPIPEIF DFS Subtraction Direction

The [IPIPEIF\\_CFG2\[5\]](#) DFSDIR bit selects how the DFS subtraction is performed.

- Set the [IPIPEIF\\_CFG2\[5\]](#) DFSDIR bit to 0 when the RAW data is coming from the VP/ISIF and the dark frame is stored in SDRAM.
- Set the [IPIPEIF\\_CFG2\[5\]](#) DFSDIR bit to 1 when the RAW data is coming from SDRAM and the dark frame is coming from the VP/ISIF.

After subtraction, a clip ensures that the value is not negative.

[Table 8-316](#) lists the different modes supported in DFS.

**Table 8-316. ISS ISP IPIPEIF DFS Modes Supported**

Description	DFDIR Value
Dark frame subtract of 8-bit RAW image stored in SDRAM from image from VP	<a href="#">IPIPEIF_CFG2[5]</a> DFSDIR = 0x0
Dark frame subtract of 8-bit RAW image stored in SDRAM from image from ISIF	<a href="#">IPIPEIF_CFG2[5]</a> DFSDIR = 0x0
Dark frame subtract of 8-bit RAW image from VP from image read from SDRAM through the BL	<a href="#">IPIPEIF_CFG2[5]</a> DFSDIR = 0x1

---

**NOTE:** DFS input depends on the INPSRC1 and INPSRC2 settings.

---

### 8.3.3.3.8 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for IPIPE Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled ([IPIPEIF\\_CFG1\[1\]](#) DECIM), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can be enabled by setting the [IPIPEIF\\_CFG1\[7\]](#) AVGFILT bit. It operates on every other pixel (same color) in RAW Bayer input or every Y component in YCbCr data in the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 * \text{input}[i] + \text{input}[i + 1]) \gg 2$$

The averaging filter operates on every other pixel (same color) in RAW Bayer input or YUV data.

If the data is YUV4:2:2, the option to average and decimate is given under the conditions listed in [Table 8-317](#).

**Table 8-317. ISS ISP IPIPEIF Averaging Filter Conditions for YUV4:2:2 Data**

<b>IPIPEIF_CFG1[3:2] INPSRC2</b>	<b>IPIPEIF_CFG2[3] YUV16</b>	<b>Comments</b>
0	1	YUV4:2:2 data is coming from the ISIF module. Averager and decimation is possible on the data path to the IPIPE module.
1	1	YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
3		YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module.
Other value	Other value	For YUV4:2:2 data, averager and decimation is not possible on the data path to the IPIPE module.

The averager implements a (1, 2, 1) FIR filter on Luma and Chroma. The following registers have a part in the behavior of the YUV data averaging and decimation:

- [IPIPEIF\\_INIRSZ\[12:0\]](#) INIRSZ
- [IPIPEIF\\_CFG1\[7\]](#) AVGFILT
- [IPIPEIF\\_CFG1\[1\]](#) DECIM

#### **8.3.3.3.9 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for IPIPE Data Path**

The IPIPE input is limited to 5376 pixels per horizontal line due to restrictions in the line memory width in the IPIPE.

To process image sensor resolutions with more than 5376 pixels per line with no resolution loss, vertical frame division mode (FDM) must be used; that is, the image must be divided into vertical chunks of less than 5376 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

Alternatively, if a loss in resolution is acceptable, the line width decimator (the [IPIPEIF\\_CFG1\[1\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 5376 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF\\_RSZ\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF\\_INIRSZ\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF\\_INIRSZ\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator, as shown in [Figure 8-128](#).

**Figure 8-128. ISS ISP IPIPEIF Resizer Offset Definition**

### 8.3.3.3.10 ISS ISP IPIPEIF RAW Data Gain for IPIPE Data Path

A gain factor ranging from 0.00195(1/512) to 1.99805(1023/512) is multiplied to the RAW output of the IPIPEIF. The gain is not applied if the input data is YCbCr. The gain constant is set in the [IPIPEIF\\_GAIN\[9:0\]](#) GAIN bit field using U10Q9 format.

The output value is clipped after gain control through the value of the [IPIPEIF\\_OCLIP\[11:0\]](#) OCLIP bit field.

### 8.3.3.3.11 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for H3A Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (the [IPIPEIF\\_RSZ3A\[9\]](#) DECIM bit), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can also be used to reduce noise before H3A statistics generation. It operates on every other pixel (the same color) in a RAW Bayer input or every Y component in YCbCr data. The averaging filter can be enabled by setting the [IPIPEIF\\_RSZ3A\[8\]](#) AVGFILT bit, and it operates with the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 * \text{input}[i] + \text{input}[i + 1]) \gg 2$$

### 8.3.3.3.12 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for H3A Data Path

The H3A input is limited to 3008 pixels per horizontal line due to restrictions in the line memory width in the H3A.

To process image-sensor resolutions with more than 3008 pixels per line with no resolution loss, vertical frame division mode (FDM must be used); that is, the image must be divided into vertical chunks of less than 3008 pixels, and each chunk must be processed sequentially by the ISP. FDM is memory-to-memory processing and is not supported on the fly.

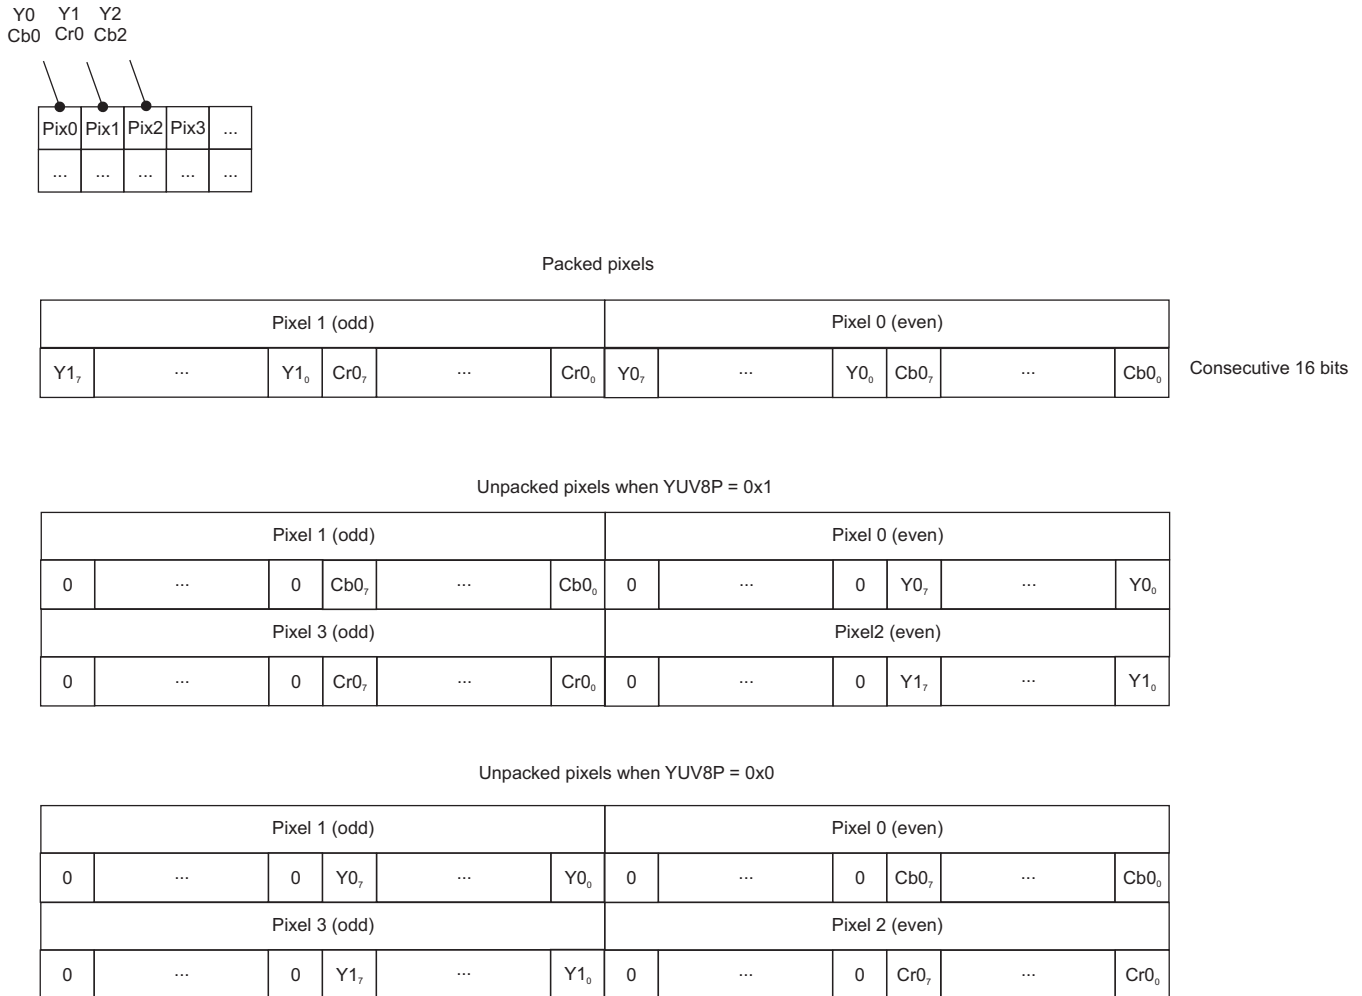

Alternatively, if loss of resolution is acceptable, the line width decimator (the [IPIPEIF\\_RSZ3A\[9\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 3008 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF\\_RSZ3A\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF\\_INIRSZ3A\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF\\_INIRSZ3A\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator (see [Figure 8-128](#)).

**8.3.3.3.13 ISS ISP IPIPEIF YUV4:2:2 8-bits Packed Data Input Coming From ISIF Module**

This section applies when data coming from the ISIF is 8 bits (IPIPEIF\_CFG2[6] YUV8 = 0x1). When IPIPEIF\_CFG1[3:2] INPSRC2 = 0 and IPIPEIF\_CFG2[3] YUV16 = 1, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the IPIPEIF\_CFG2[7] YUV8P bit. See Figure 8-129.

**Figure 8-129. ISS ISP IPIPEIF YUV8P Settings**

camss-616

**8.3.3.3.14 ISS ISP IPIPEIF YUV4:2:0 Data Input for Memory-to-Memory Resize Operations**

The ISP RSZ module can resize YUV4:2:0 data. The YUV4:2:0 data can come from the memory (through BL) or from the VP through the CCP2 RX module, which reads data from SDRAM and pushes it to the IPIPEIF module VP. The possible data paths are:

- SDRAM -> IPIPEIF (BL) -> RESIZER -> SDRAM
- SDRAM -> CCP2 RX -> IPIPEIF (VP) -> RESIZER -> SDRAM
- SDRAM -> IPIPEIF (BL) -> IPIPE -> RESIZER -> SDRAM
- SDRAM -> CCP2 RX -> IPIPEIF (BL) -> IPIPE -> RESIZER -> SDRAM

When the data comes from BL, the IPIPEIF module must be set up to process the luminance data first, and then the chrominance data.

- For 420Y (first pass):
  - IPIPEIF\_CFG1[15:14] INPSRC1 = 0x1 (SDRAM data input)

- IPIPEIF\_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
- IPIPEIF\_CFG1[13:11] DATASFT = 0x0 (no data shift)
- IPIPEIF\_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
- IPIPEIF\_CFG2[3] YUV16 = 0x1 (data\_input [7:0] = 0 and data\_input [15:8] = valid)
- For 420C (second pass):
  - IPIPEIF\_CFG1[15:14] INPSRC1 = 0x1 (SDRAM data input)
  - IPIPEIF\_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
  - IPIPEIF\_CFG1[13:11] DATASFT = 0x0 (no data shift)
  - IPIPEIF\_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
  - IPIPEIF\_CFG2[3] YUV16 = 0x0 (data\_input[7:0] = valid and data\_input [15:8] = 0)

### 8.3.3.3.15 ISS ISP IPIPEIF Module Events and Status Checking

The IPIPEIF module generates an IPIPEIF event through the IPIPEIF\_IRQ interrupt at the end of each frame. This interrupt is set through the [ISP5\\_IRQENABLE\\_SET\\_i\[9\]](#) IPIPEIF\_IRQ bit. The input interrupt source generation is selected through the [IPIPEIF\\_CFG2\[0\]](#) INTSW bit in a certain configuration. The following pseudo code describes INTSW.

```
if (IPIPEIF_CFG2[0] INTSW==0) // Interrupt source from VP
  if (IPIPEIF_CFG1[15:14] INPSRC1==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else // In continuous mode
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
  else // IPIPEIF_CFG1[15:14] INPSRC1==0, data is from VP
    Interrupt is the start position of VD from VP

else // Interrupt source from ISIF: IPIPEIF_CFG2[0] INTSW==1
  if (IPIPEIF_CFG1[3:2] INPSRC2==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
  else // IPIPEIF_CFG1[3:2] INPSRC2==0, data is from ISIF
    Interrupt is the start position of VD from ISIF
```

In addition to this interrupt, the host must check the IPIPEIF\_DTUF status flag of the [ISP5\\_IRQSTATUS\\_RAW2\\_i\[1\]](#) IPIPEIF\_UDF bit (if this is enabled and mapped to the ISP IRQ lines) to see if an underflow occurred. For more information, see [Section 8.3.4.3.4](#).

### 8.3.3.4 ISS ISP IPIPE Functional Description

#### 8.3.3.4.1 ISS ISP IPIPE Overview

- The input interface extracts the valid region from the Bayer RAW data:
  - Up to 12-bit input pixel resolution
  - Requires at least 8 pixels for horizontal blanking and four lines for vertical blanking. In one-shot mode; 16 blanking lines after processing area are required.
  - The maximum horizontal and vertical offset of IPIPE processing area from synchronous signal is 65534.
  - Supports RGB Bayer pattern for input
- The DPC module fixes defect pixels using two methods: LUT-based and on-the-fly adaptive.
- The 2D noise-filter module reduces noise in RAW data.
- The green-imbalance-correction (GIC) module reduces Gb/Gr difference to remove line crawl noise.
- The white balance module applies offset and gain adjustments to each color.
- The Color filter array (CFA) interpolation module implements CFA interpolation. The output from the CFA interpolation module is RGB-4:4:4 formatted data. CFA also reduces aliasing caused by

undersampling by digital anti-aliasing (DAA).

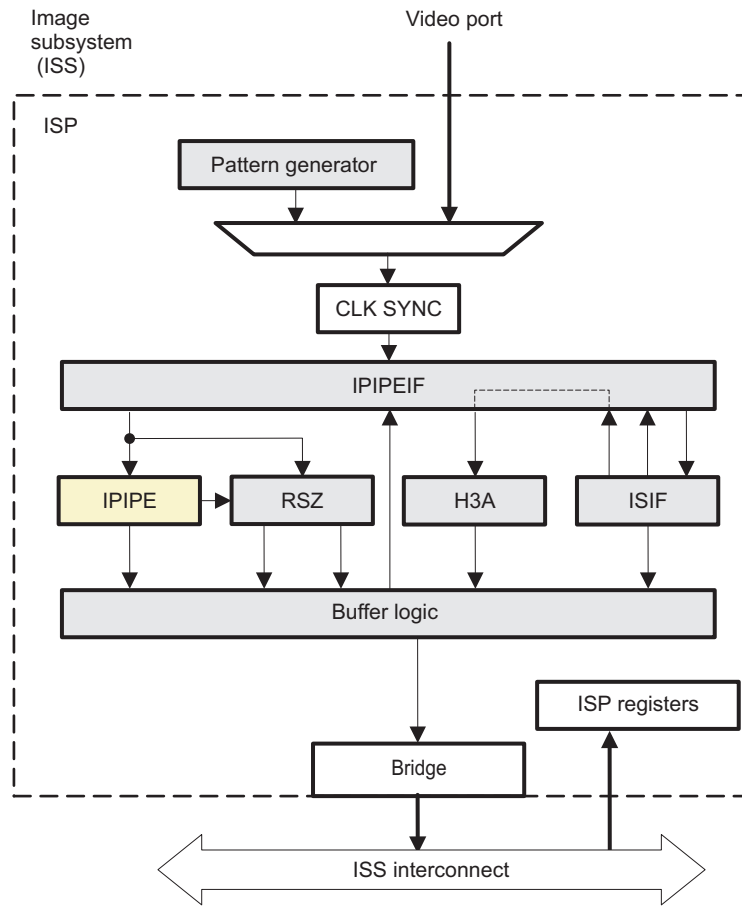

- The RGB2RGB blending module applies a  $3 \times 3$  matrix transform to the RGB data generated by the CFA interpolation module.
- The gamma correction module independently applies gamma correction to each RGB component. Gamma is implemented using a piece-wise linear interpolation approach with a 512-entry LUT for each color.
- The 2nd RGB2RGB blending module applies a  $3 \times 3$  matrix transform to the RGB data after gamma correction.
- 3D-LUT converts RGB data to RGB data using  $9 \times 9 \times 9$  table and tetrahedral interpolation.
- The RGB2YCbCr conversion module applies  $3 \times 3$  matrix transformation to the RGB data to convert it to YCbCr data. This module also implements offset. The global brightness and contrast enhancement module fixes brightness and contrast tone.
- The 4:2:2 conversion module applies the chroma low pass filter and downsampling to Cb and Cr to convert 4:4:4 data to 4:2:2 data.
- The 2D edge-enhancer module improves image clarity with a luminance nonlinear filter.
- The chroma artifact reduction module reduces color artifacts using gain control and a 2D median filter.
- The output interface module transfers data from IPIPE to SDRAM in the form of one YCbCr (4:2:2 or 4:2:0), RGB (32/16 bits), or Bayer data.
- The histogram function can record histograms of up to four distinct areas into up to 256 bins.
- The boxcar function makes 1/8 or 1/16 size (1/64 or 1/256 in area) images.
- The boundary signal calculator (BSC) makes vectors of row and column summations.

IPIPE has four different processing paths:

- Case 1: IPIPE reads CCD RAW data and applies all IPIPE functions and stores the YCbCr (or RGB) data to SDRAM.
- Case 2: IPIPE reads CCD RAW data and stores the Bayer data after white balance to SDRAM.
- Case 3: IPIPE reads YCbCr-4:2:2 data and applies edge enhance, chroma suppression, and resize to output YCbCr data to SDRAM.
- Case 4: IPIPE reads YCbCr-4:2:0 data and applies resize to output YCbCr data to SDRAM.

[Figure 8-130](#) shows the connections from the IPIPE module to other submodules of the ISP.

**Figure 8-130. ISS ISP IPIPE High-Level Diagram**

camss-003d

**8.3.3.4.2 ISS ISP IPIPE Top-Level Block Diagram**

The IPIPE is a programmable hardware image-processing module that generates image data in YCbCr-4:2:2 or YCbCr-4:2:0 format from RAW CCD/CMOS data. The IPIPE module supports output of Bayer data.

The IPIPE module supports RAW data in Bayer format, as shown in [Figure 8-131](#). Other RGB formats or complimentary color formats are not supported.

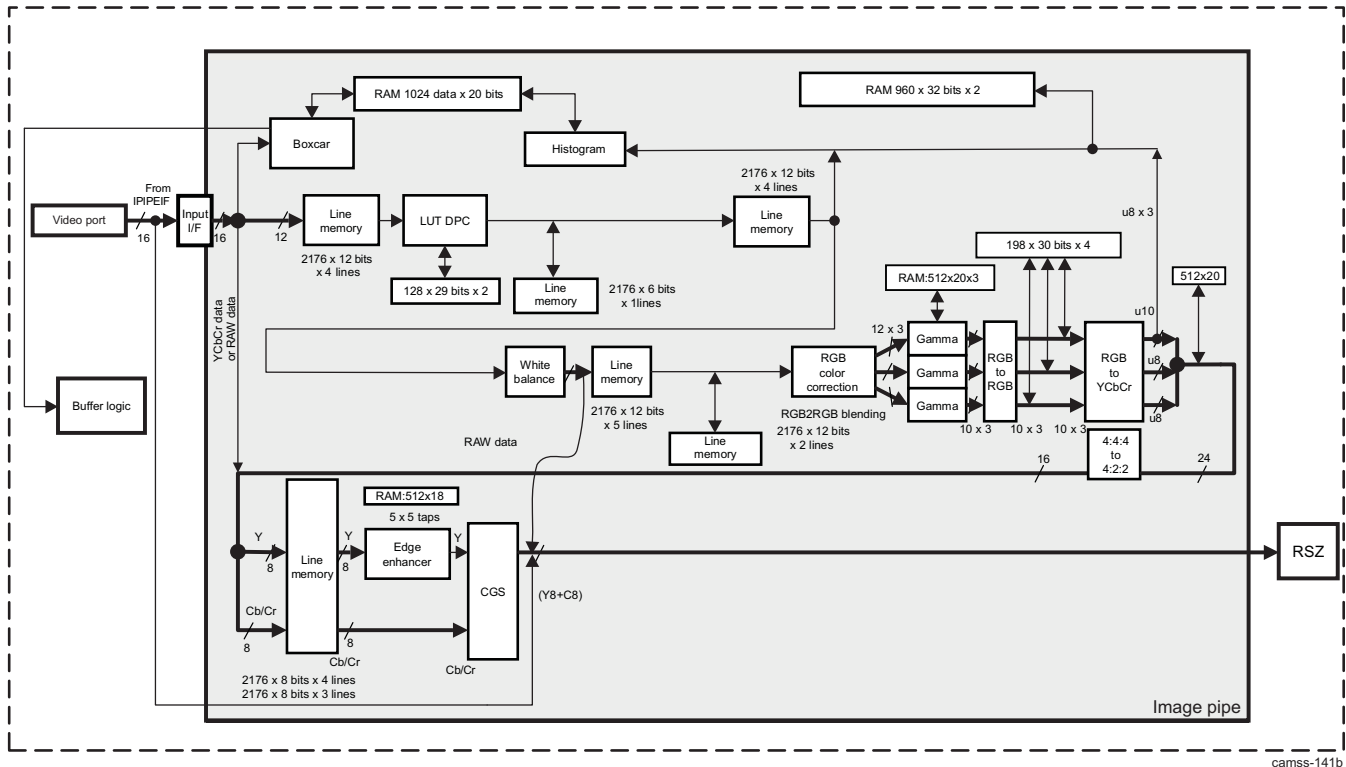

**Figure 8-131. ISS ISP IPIPE Supported CFA Format**

camss-142

As shown in [Figure 8-132](#), many internal modules are used to process Bayer data into YCbCr data

Figure 8-132. ISS ISP IPIPE Module Block Diagram

### 8.3.3.4.3 ISS ISP IPIPE Input Interface

The IPIPE module receives 12-bit RAW image data or 16-bit YCbCr data through the IPIPEIF module. The IPIPE module can work with up to 5376 pixels in each horizontal line, except in RAW pass-through mode. If the image width is larger than 5376, the image must be scaled down at the IPIPEIF module level. Otherwise, the input image must be split into several blocks.

If the input data is YCbCr, all RGB processing modules are skipped, and only edge enhancer and chroma suppression are applied to the input data.

If the input data is YCbCr-4:2:0, only Y or C can be processed at a time, and only the resizer process can be applied. Because the resizer is outside the ISIF module, the data is passed to it directly by skipping the RGB and YCbCr processing modules.

In RAW pass-through mode, images up to 8190 pixels per line can be processed. In RAW pass-through mode, the input data is written out directly to SDRAM.

The IPIPE module is enabled through the [IPIPE\\_SRC\\_EN\[0\]](#) EN bit.

The IPIPEIF module must be selected as the IPIPE module source with the [IPIPE\\_SRC\\_MODE\[1\]](#) WRT bit set to 1 from the input port of the IPIPEIF. This is required to enable and transfer data properly from the interface to the IPIPE.

The IPIPE module has two processing modes, which can be selected through the [IPIPE\\_SRC\\_MODE\[0\]](#) OST bit:

- One-shot mode: [IPIPE\\_SRC\\_MODE\[0\]](#) OST = 0x1
- Free-run mode: [IPIPE\\_SRC\\_MODE\[0\]](#) OST = 0x0

The input and output formats are selected in the [IPIPE\\_SRC\\_FMT\[1:0\]](#) FMT bit field (see [Table 8-318](#)).

**Table 8-318. ISS ISP IPIPE Input and Output Selections**

<b>IPIPE_SRC_FMT[1:0] FMT</b>	<b>IPIPE Module Input</b>	<b>IPIPE Module Output</b>
0x0	RAW Bayer	YCbCr or RGB
0x1	RAW Bayer	RAW Bayer
0x2	RAW Bayer	Disabled
0x3	YCbCr 16 bits	YCbCr

The input to the IPIPE module is in the formats (YCbCr-8bit is not allowed) shown in [Figure 8-133](#).

**Figure 8-133. ISS ISP IPIPE Module Input Format**

IPIPE input	RAW YCbCr 16bit	LOW	LOW	LOW	LOW	RAW11	RAW10	RAW9	RAW8	RAW7	RAW6	RAW5	RAW4	RAW3	RAW2	RAW1	RAW0
		Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Cb/Cr7	Cb/Cr6	Cb/Cr5	Cb/Cr4	Cb/Cr3	Cb/Cr2	Cb/Cr1	Cb/Cr0
	Y 8bit	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	LOW	LOW	LOW	LOW	LOW	LOW	LOW	LOW
	CbCr 8bit	LOW	LOW	LOW	LOW	LOW	LOW	LOW	LOW	Cb/Cr7	Cb/Cr6	Cb/Cr5	Cb/Cr4	Cb/Cr3	Cb/Cr2	Cb/Cr1	Cb/Cr0

camss-143

The window to process can be defined by its vertical and horizontal start position ([IPIPE\\_SRC\\_VPS](#) and [IPIPE\\_SRC\\_HPS](#)) and vertical and horizontal size ([IPIPE\\_SRC\\_VSZ](#) and [IPIPE\\_SRC\\_HSZ](#)). [Figure 8-134](#) shows the window settings for processing.

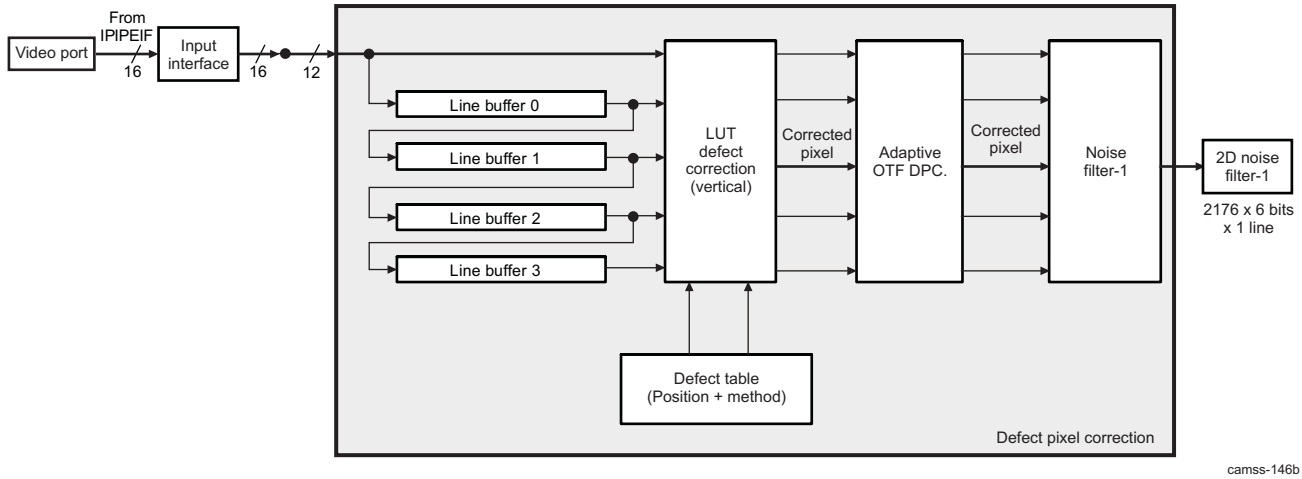

**Figure 8-134. ISS ISP IPIPE Module Processing Window Settings**

camss-639

#### 8.3.3.4.4 ISS ISP IPIPE Defect Pixel Correction

The DPC module corrects defect pixels using two methods: look-up-table-based method (LUT DPC) and on-the-fly adaptive method (OTF DPC). [Figure 8-135](#) shows defect pixel correction.

Figure 8-135. ISS ISP IPIPE Defect Pixel Correction

camss-146b

8.3.3.4.1 ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

LUT DPC is the first stage of the IPIPE image-processing pipeline. The LUT DPC module corrects defects in input data. It supports up to a 256-defect point table. However, the table can be renewed as required during image processing. Therefore, the maximum amount of defect information is limited only by system-level performance.

The module uses two sets of 128 x 29 memories to hold defect information. The table contains the information of horizontal position (13 bits), vertical position (13 bits), and correction method (3 bits), as shown in Table 8-319. The LUT DPC is enabled through the IPIPE\_DPC\_LUT\_EN[0] EN bit.

Table 8-319. ISS ISP IPIPE Defect Information Packing

Correction Method	Vertical Position	Horizontal Position
28...26	25...13	12...0

The information must be listed in the order of "from left to right" and "from the top to bottom." The first position in the defect information table and the number of defects that are used can be specified. The address of the table must be programmed in the IPIPE\_DPC\_LUT\_ADR[9:0] ADR bit field. Thus, the address of the first valid data is stated.

The LUT type can be:

- With a finite number of entries:
  - IPIPE\_DPC\_LUT\_SEL[1] TBL = 0x0
  - The size of the LUT is set in the IPIPE\_DPC\_LUT\_SIZ[9:0] SIZ bit field.
- With an infinite number of entries:
  - IPIPE\_DPC\_LUT\_SEL[1] TBL = 0x1

The correction methods, set in Table 8-319, are described in Table 8-320.

Table 8-320. ISS ISP IPIPE Correction Method Description

Correction Method	d0 =	Comment
0	Black or white dot	Replace with a black (or white) dot to force OTF-DPC to work on the pixel. White or black dot replacement can be selected through the IPIPE_DPC_LUT_SEL[0] DOT field.
1	d4	Copy from left
2	d5	Copy from right

**Table 8-320. ISS ISP IPIPE Correction Method Description (continued)**

Correction Method	d0 =	Comment
3	$(d4 + d5)/2$	Horizontal interpolation
4	$(d2 + d7)/2$	Vertical interpolation
5	d2	Copy from top
6	d7	Copy from bottom
7	$(d2 + d4 + d5 + d7)/2$	2D interpolation

The pixels in the defect correction algorithm are numbered as shown in [Figure 8-136](#).

**Figure 8-136. ISS ISP IPIPE Pixel Numbering in Defect Correction Algorithm**

camss-145

The pixels at the edges are mirrored in the way described in [Figure 8-137](#). The figure shows the typical correction by overwriting far-edge pixels and mirroring them with other edge pixels. The example shows how by using a noise filter the correct-by-definition pixels are copied over bad pixels.

**Figure 8-137. ISS ISP IPIPE Mirroring in Defect Correction and Noise Filter**

(Right, top, and bottom edges have the same process.)

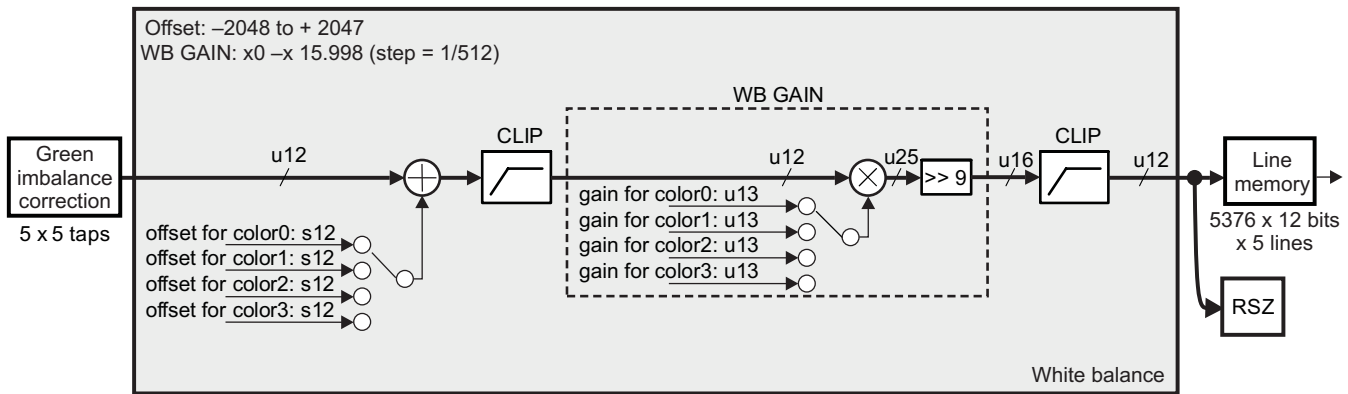

camss-147

#### 8.3.3.4.5 ISS ISP IPIPE White Balance

The white balance module executes white balance to each color component. White balance gain adjusts the ratio of each color existing in a CFA pattern. An offset can be applied before white balance correction (IPIPE\_WB2\_OFT\_R, GR, Gb, or B registers).

[Figure 8-138](#) is a block diagram of the white balance module. In the white balance gain adjuster, the RAW data is multiplied by a selected gain (IPIPE\_WB2\_WGN\_R, Gr, Gb, or B registers) corresponding to the color. The white balance gain can be selected from four 13-bit values. Firmware can assign any combination of 4 pixels in horizontal and vertical directions. The precision of each gain is shown in the figure.

Figure 8-138. ISS ISP IPIPE White Balance

camss-155

### 8.3.3.4.6 ISS ISP IPIPE RGB2RGB Blending Module

The RGB2RGB blending module transforms the RGB data generated by the CFA interpolation module using a 3 x 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 8-139. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, and is set in the `IPIPE_RGB1_MUL_RR` to `IPIPE_RGB1_MUL_BB` registers. The offset range for each component is from -4096 to 4095, and is set in the `IPIPE_RGB1_OFT_OR` to `IPIPE_RGB1_OFT_OB` registers.

Figure 8-139. ISS ISP IPIPE RGB2RGB Conversion Formula

$$\begin{pmatrix} R\_out \\ G\_out \\ B\_out \end{pmatrix} = \begin{pmatrix} gain\_RR & gain\_GR & gain\_BR \\ gain\_RG & gain\_GG & gain\_BG \\ gain\_RB & gain\_GB & gain\_BB \end{pmatrix} \begin{pmatrix} R\_in \\ G\_in \\ B\_in \end{pmatrix} + \begin{pmatrix} offset\_r \\ offset\_G \\ offset\_B \end{pmatrix}$$

camss-650

### 8.3.3.4.7 ISS ISP IPIPE Gamma Correction Module

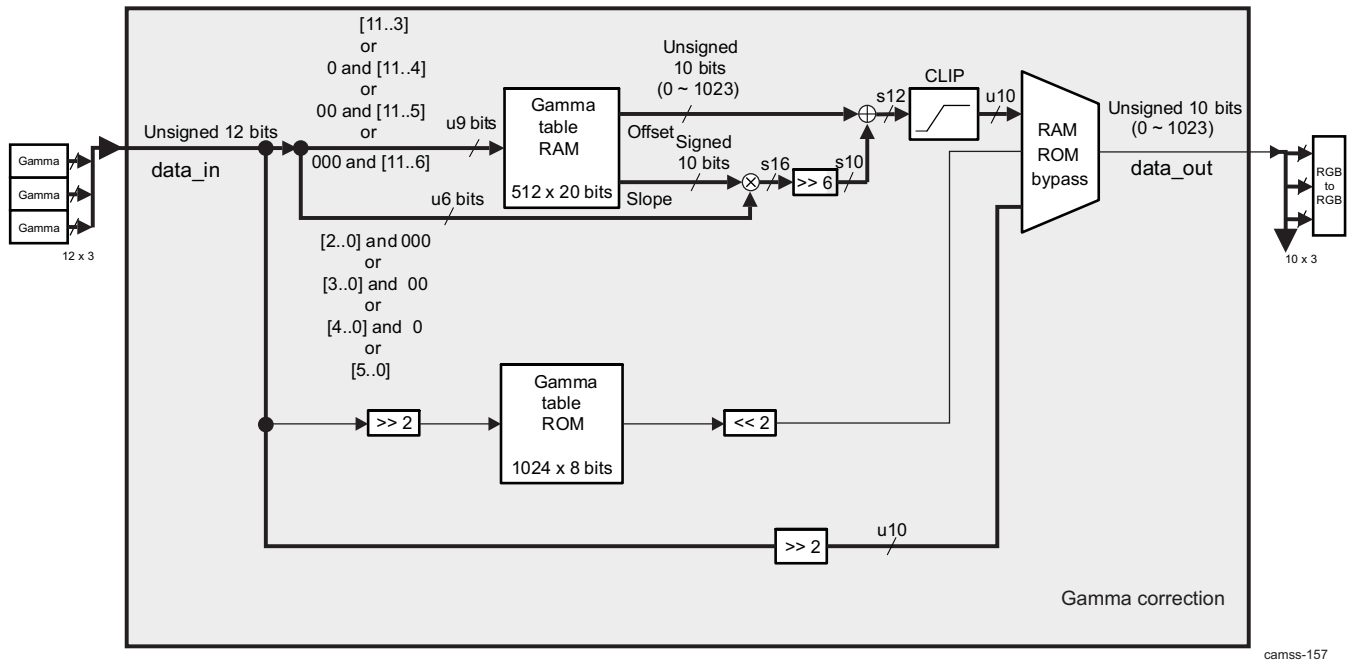

**NOTE:** For the memory access locations of the gamma correction module, see Section 8.3.3.9.

The gamma correction module performs gamma correction independently for each color in the RGB color space by using a piece-wise linear interpolation. ROM tables and RAM tables are selectable through the `IPIPE_GMM_CFG[4]` TBL bit. Each ROM table and RAM table has 512-entries, and each entry accommodates a 10-bit offset and 10-bit slope. The range of slope value is from -512 to +511. The ROM table has 1024 entries and an output 8-bit value.

Figure 8-140 is a block diagram of the gamma correction module. It is composed of two tables and one selector. When the BYPASS bit is asserted, the input data is divided by 16 (the `IPIPE_GMM_CFG[0]` BYPR, `IPIPE_GMM_CFG[1]` BYPG, and `IPIPE_GMM_CFG[2]` BYPB bits).

Figure 8-141 shows an example of the gamma curve. Figure 8-142 shows offset and slope packing.

Figure 8-140. ISS ISP IPIPE Gamma Correction Module Block Diagram

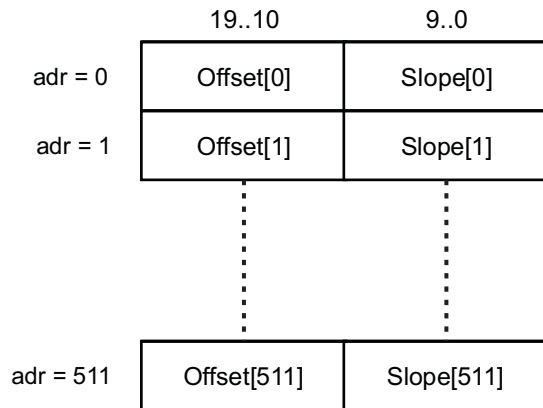

camss-157

Figure 8-141. ISS ISP IPIPE Gamma Curve Example

camss-158

Figure 8-142. ISS ISP IPIPE Gamma Table Offset/Slope Packing

camss-159

8.3.3.4.8 ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix

The second RGB2RGB blending module transforms the RGB data after gamma correction using the 3 × 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 8-143. Each gain range is from -4 to +3.996 with step 1/256 = 0.004 (s3.8), and is set in the IPIPE\_RGB2\_MUL\_RR to IPIPE\_RGB2\_MUL\_BB registers. The offset is -1024 to 1023 (s11), and is set in the IPIPE\_RGB2\_OFT\_OR to IPIPE\_RGB2\_OFT\_OB registers.

Figure 8-143. ISS ISP IPIPE RGB2RGB 2nd Conversion Formula

$$\begin{pmatrix} R\_out \\ G\_out \\ B\_out \end{pmatrix} = \begin{pmatrix} gain\_RR & gain\_GR & gain\_BR \\ gain\_RG & gain\_GG & gain\_BG \\ gain\_RB & gain\_GB & gain\_BB \end{pmatrix} \begin{pmatrix} R\_in \\ G\_in \\ B\_in \end{pmatrix} + \begin{pmatrix} offset\_r \\ offset\_G \\ offset\_B \end{pmatrix}$$

camss-650

8.3.3.4.9 ISS ISP IPIPE RGB2YCbCr Conversion Matrix

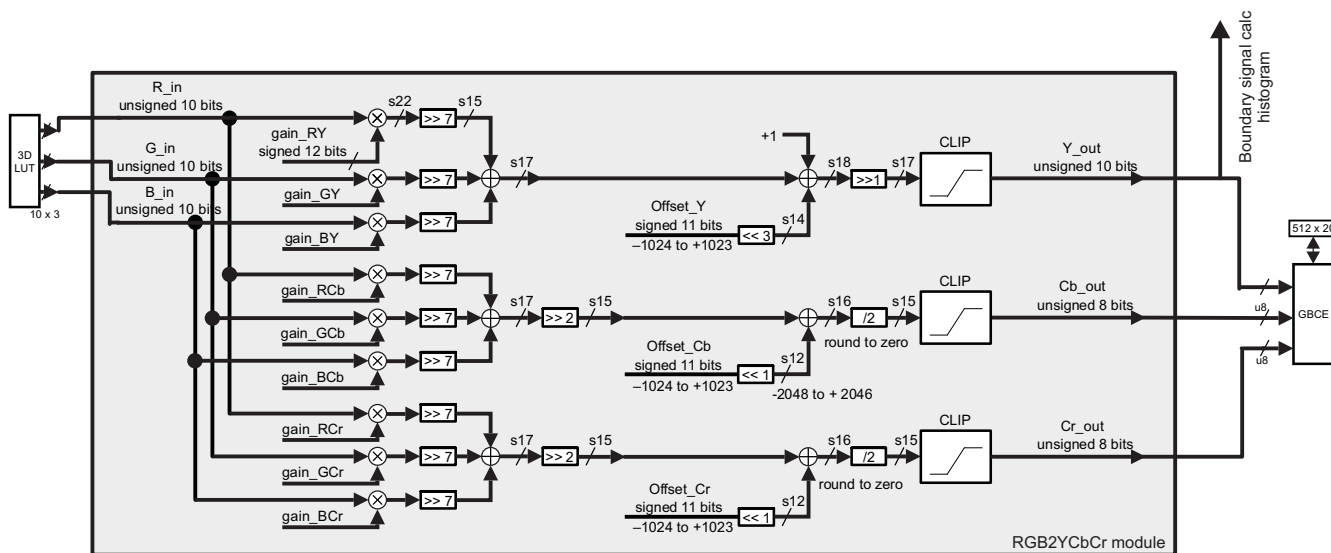

This module transforms the RGB data to YCbCr data format using a 3 × 3 matrix transformation in combination with an added offset. While transferring, the brightness control and contrast control can be adjusted using the IPIPE\_YUV\_ADJ[8:15] BRT and IPIPE\_YUV\_ADJ[8:15] CRT bit fields, respectively. Then, the transform is calculated using the formula shown in Figure 8-144. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, configured in the IPIPE\_YUV\_MUL\_RY to IPIPE\_YUV\_MUL\_BCr registers. The offset is -1024 to 1023 for Y, Cb, and Cr, configured in the IPIPE\_YUV\_OFT\_Y to IPIPE\_YUV\_OFT\_Cr registers. Figure 8-145 is the block diagram of the RGB to RGB blending module. The output is calculated by the equation.

Figure 8-144. ISS ISP IPIPE RGB2RGB 2nd Conversion Formula

$$\begin{pmatrix} Y\_out \\ Cb\_out \\ Cr\_out \end{pmatrix} = \begin{pmatrix} gain\_RY & gain\_GY & gain\_BY \\ gain\_RCb & gain\_GCb & gain\_BCb \\ gain\_RCr & gain\_GCr & gain\_BCr \end{pmatrix} \begin{pmatrix} R\_in \\ G\_in \\ B\_in \end{pmatrix} + \begin{pmatrix} offset\_Y \\ offset\_Cb \\ offset\_Cr \end{pmatrix}$$

camss-654

Figure 8-145. ISS ISP IPIPE RGB2YCbCr Module Block Diagram

camss-161

### 8.3.3.4.10 ISS ISP IPIPE 4:2:2 Conversion Module

The 4:2:2 conversion module converts the image data to YCbCr-4:2:2 format by taking the average of every two Cb and Cr components. Y and Cb/Cr sampling point of spatial cosited or spatial centering are selectable using the `IPIPE_YUV_PHS[0]` POS register. Horizontal 3 taps and 4- or 2-tap filters are used for spatial cosited and spatial centering, respectively. The module is enabled from the `IPIPE_YUV_PHS[1]` PLF bit.

**Figure 8-146. ISS ISP IPIPE Chroma Subsampling Position**

camss164

Figure 8-147 is a block diagram of the 4:2:2 conversion module.

**Figure 8-147. ISS ISP IPIPE 4:2:2 Conversion Module Block Diagram**

camss-165

### 8.3.3.4.11 ISS ISP IPIPE 2D Edge Enhancer

**NOTE:** For the location of 2D edge-enhancer memory accesses, see [Section 8.3.3.9](#).

The edge-enhancer module operates on the luminance (Y data) component of images to improve the image quality and can be enabled from the `IPIPE_YEE_EN[0]` EN bit. Edges in input images are detected by a 2D high-pass filter, and its sharpness is increased by the value from a non-linear table. [Figure 8-148](#) shows a block diagram of the luminance non-linear edge-enhancer. Entry for the non-linear table is 10-bit and the output is in signed 9-bit.

In edge-enhancer mode when `IPIPE_YEE_TYP[0]` SEL is set to 0, linear filter with programmable coefficient is applied to the Y input. Here, M is a 5 × 5 matrix with programmable coefficients (`IPIPE_YEE_MUL_xx`, where x = 00, 01, 02, 10, 11, 12, 20, 21, 22). A down shift of high pass filter is applied to the edge enhancer from the `IPIPE_YEE_SHF[3:0]` SHF bit field (shgHPF in the formula).

Then, the HPF value is shrunk by a threshold value (u6) specified by the `IPIPE_YEE_THR` register (thresholdHPF in the formula), and clipped to signed 10 bits to get the index for the LUT.

**Figure 8-148. ISS ISP IPIPE 2D Edge-Enhancer Indexing**

$$index = clip(\text{shrink}(HPF, threshold_{HPF}), -512, 511)$$

$$\text{shrink}(x, threshold) = \begin{cases} x + threshold & x < -threshold \\ 0 & -threshold \leq x \leq threshold \\ x - threshold & threshold < x \end{cases}$$

$$\text{clip}(x, limit_{LOW}, limit_{HIGH}) = \begin{cases} -limit_{LOW} & x < -limit_{LOW} \\ x & -limit_{LOW} \leq x \leq limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH} < x \end{cases}$$

camss-661

Moreover, the edge-enhancement intensity is looked up from the LUT through the formula shown in [Figure 8-149](#) and in [Table 8-321](#).

**Figure 8-149. ISS ISP IPIPE 2D Edge Intensity LUT Formula**

$$E_{int} = LUT[index]$$

camss-662

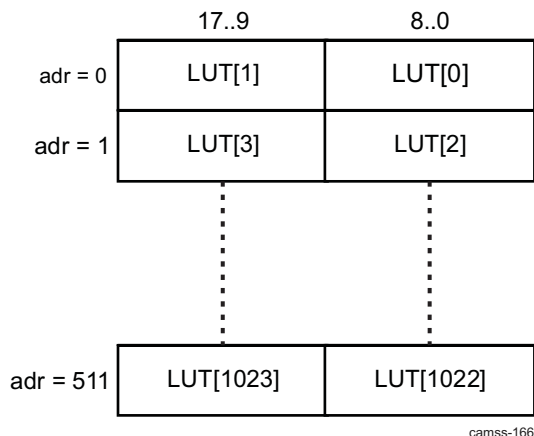

**Table 8-321. ISS ISP IPIPE Edge-Enhancer LUT Mapping**

Address (32-bit Word Address)	Bit Position	LUT Index
0x00000h	8 .. 0	1

	17 .. 9	-1

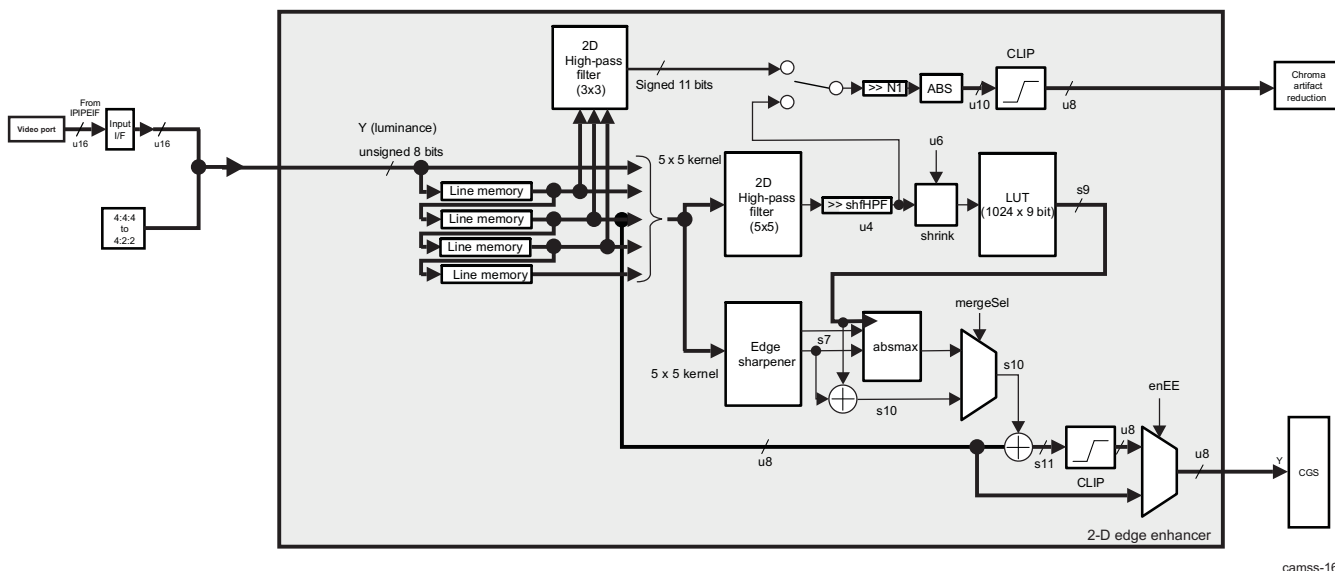

Figure 8-150 shows the LUT packing, and Figure 8-151 shows the 2D edge-enhancer block diagram.

**Figure 8-150. ISS ISP IPIPE 2D Edge-Enhancer LUT Packing**

**Figure 8-151. ISS ISP IPIPE 2D Edge-Enhancer Block Diagram**

In edge sharpener mode, enabled when `IPIPE_YEE_TYP[0] SEL = 1`, edge clarity is enhanced without producing a Halo artifact. In this module, edge intensity is derived by the 2D linear filter with fixed coefficients shown in Figure 8-152.

**Figure 8-152. ISS ISP IPIPE Edge Sharpener Details**

$$S_{i,j} = \begin{pmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{pmatrix}$$

$$sharpness(h,v) = clip \left( shrink \left( g \times \left( \sum_{j=-2}^2 \sum_{i=-2}^2 S_{i,j} Y(h+i,v+j) \right) \gg 3, threshold_{LOW} \right) \gg 6, -threshold_{HIGH}, threshold_{HIGH} \right)$$

camss-663

The gain (g) and threshold values for the shrink/clip function (threshold<sub>LOW</sub>, threshold<sub>HIGH</sub>) are determined by the [IPIPE\\_YEE\\_E\\_GAN](#), [IPIPE\\_YEE\\_E\\_THR\\_1](#) and [IPIPE\\_E\\_YEE\\_THR\\_2](#) registers. The bit width of g and threshold<sub>HIGH</sub> is in U6, and threshold<sub>LOW</sub> is in U12Q6.

This edge intensity is then clipped by a threshold value in the formula shown in [Figure 8-153](#).

**Figure 8-153. ISS ISP IPIPE 2D Edge-Intensity Clipping Formula**

$$S_{int} = \begin{cases} clip(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

camss-664

The threshold value (grad) is a function of the activity around the target pixel, which is derived from gradient values. Gain and offset are specified by [IPIPE\\_YEE\\_G\\_GAN](#) and [IPIPE\\_YEE\\_G\\_OFT](#)

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

The output from edge enhancer and edge sharpener are merged with the function shown in [Figure 8-154](#).

**Figure 8-154. ISS ISP IPIPE 2D Edge Enhancer and Sharpener Merger Formula**

$$E_{merge} = \begin{cases} E_{int} + S_{int} & IPIPE\_YEE\_TYP[0]SEL = 0 \\ absmax(E_{int}, S_{int}) & IPIPE\_YEE\_TYP[0]SEL = 1 \end{cases}$$

$$absmax(x, y) = \begin{cases} x & abs(y) \leq abs(x) \\ y & otherwise \end{cases}$$

camss-666

The E<sub>merge</sub> value is added to the Y input value to make the final output.

For chroma suppression, another 2D high pass filter (HPF) is implemented. One of the four coefficient sets shown in [Figure 8-155](#) is selectable.

**Figure 8-155. ISS ISP IPIPE 2D Edge Chroma-Suppression Coefficient Sets**

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 0 \\ 1 & -2 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 0 \\ 0 & -2 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \text{ or } \begin{pmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

camss-667

At the end of the edge enhancer process, brightness and contrast adjustment are applied to the Y signal. The formula shown in [Figure 8-156](#) describes the process.

**Figure 8-156. ISS ISP IPIPE 2D Edge-Brightness and Contrast Adjustments Formula**

$$Y_{ctr\_brt} = clip8(clip8((Y_{EE} \times CTR) \gg 4) + BRT)$$

$$clip8(x) = \begin{cases} x & x \leq 255 \\ 255 & 255 < x \end{cases}$$

camss-668

In the formula from [Figure 8-156](#), Y<sub>EE</sub> is the output (Y) of the Edge-Enhancer, as shown in [Figure 8-151](#), CTR is a U8Q4 contrast enhancement factor (configured through [IPIPE\\_YUV\\_ADJ\[7:0\]](#) CTR bit field), BRT is a U8 brightness enhancement factor (configured through the [IPIPE\\_YUV\\_ADJ\[15:8\]](#) BRT bit-field), and YCTR\_BRT is the output with brightness and contrast adjustment applied.

### 8.3.3.4.12 ISS ISP IPIPE Histogram

---

**NOTE:** The boxcar function can be used simultaneously with the histogram function if needed.

---

---

**NOTE:** For the locations of histogram memory access, see [Section 8.3.3.9](#).

---

The histogram module counts the number of pixels that have a value in a region and can be enabled from the `IPIPE_HST_EN[0]` EN bit. Moreover, if enabled, the `IPIPE_HST_MODE` register can be set to work constantly or one time. If the `IPIPE_HST_MODE[0]` OST bit is set to 1, the histogram is disabled by clearing the `IPIPE_HST_EN[0]` EN bit to 0 after one run (one-shot mode).

After enabling the module, the following features are available:

- The data to be summed is taken from the DPC memory or RGB2YCbCr module. The choice is made in the `IPIPE_HST_SEL[2]` SEL bit.
- When data are collected from the DPC memory, the sampled colors are R/G/B/Y. Y is derived in the following method:

$$Y = (\text{HST\_MUL\_R} * R + \text{HST\_MUL\_GR} * Gr + \text{HST\_MUL\_GB} * Gb + \text{HST\_MUL\_B} * B) \quad (4)$$

For the G histogram, Gb, Gr, or the average is used, through the `IPIPE_HST_SEL[1:0]` TYP bit field.

- Two sets of 512 × 20-bit memory are used.
- The number of bins can be set from 32 to 256 in the `IPIPE_HST_PARA[13:12]` BIN bit field.
- The number of regions (areas) from 1 to 4; each region can be enabled through `IPIPE_HST_PARA[x]` RGNx (where x = 0 to 3). The positions of the regions are defined in `IPIPE_HST_x_VPS` and `IPIPE_HST_x_HPS`, and the vertical and horizontal size are defined by `IPIPE_HST_x_VSZ` and `IPIPE_HST_x_HSZ`, respectively (where x = 0 to 3).
- The number of regions × the number of bins ≤ 256.
- Each region can be turned on/off counting.
- The regions have priority orders.
- Each region has its own start coordinate X/Y (12 bits) and horizontal/vertical sizes (12 bits)
- When regions are overlapped, the value in the overlapped region is accumulated only in the region with the highest priority.
- The number of colors to be counted is from 1 to 4. Each color in all regions can be turned off counting (the `IPIPE_HST_PARA[7:4]` bit field).
- The value of each pixel is down-shifted (0 ~ 11) before counting using the `IPIPE_HST_PARA[11:8]` SHF bit field.
- When the value of a bin reaches ( $2^{20} - 1$ ), the value is saturated until the memory is cleared.
- Number of bins: 32, 64, 128, or 256

The histogram memory can be cleared at the VD signal. When the memory is cleared, the first line of each frame cannot be sampled by the histogram if the width of the frame is larger than 512. If the width of the frame is smaller than 512, the first ceil (512/width) lines cannot be collected, where ceil(x) is the smallest integer value above x. If the clearing function is not enabled, the histogram bins are accumulated over the previous values.

The histogram has two banks of memories, which can be switched alternatively. The two memory banks are slipped into four histogram memory tables. Only two tables can be used at a time: output memory tables 0 and 1, or tables 2 and 3. To initialize tables, the `IPIPE_HST_TBL[1]` CLR bit is set to 1, and to select which set of tables is to be used the `IPIPE_HST_TBL[0]` SEL bit can be switched between 0 and 1.

A gain for each color can be applied using the `IPIPE_HST_MUL_x` registers, where x = R, GR, GB, or B.

### 8.3.3.4.13 ISS ISP IPIPE Boxcar

The boxcar module generates a boxcar by taking mosaic image data and averaging the red, green, and blue pixels in an (8 × 8) or (16 × 16) block to produce one red, green, and blue output, as shown in [Figure 8-157](#) and in [Figure 8-158](#). Here, similar to the histogram module, the boxcar is enabled from the `IPIPE_BOX_EN[0]` EN bit, and if the mode is set to run once (one shot) (`IPIPE_BOX_MODE[0]` OST = 1), the enable bit is cleared after the run. The size of the blocks is determined from the `IPIPE_BOX_SHF[0]` SEL bit, where if set to 0 = 8 × 8, and 1 = 16 × 16.

The result of this operation is a full-color image with (1/64) or (1/256) area of the original image. The maximum input horizontal width is 8190 pixels when a 16 × 16 block is used; the width is 4096 when an 8 × 8 block is used. Also, the image size (width and height) must be multiple of 16 for a 16 × 16 block, and multiple of 8 for an 8 × 8 block. Boxcar operation works on 12-bit Bayer data and outputs 16-bit data. The output data is 48-bit RGB data for each 8 × 8 or 16 × 16 block. The 48-bit data is aligned in 64-bit format in SDRAM as shown in Section 8.3.3.4.13. The first address of SDRAM access is specified by the `IPIPE_BOX_SDR_SAD_H` and `IPIPE_BOX_SDR_SAD_L` registers. The output data are written to SDRAM continuously line by line; there is no address offset between lines. After the image transfer of each frame completes, the `ipipe_eof` signal is sent to buffer logic. This signal is issued at the same timing as `ipipe_int_dma`.

Figure 8-157. ISS ISP IPIPE Boxcar Operation (8 × 8 Block)

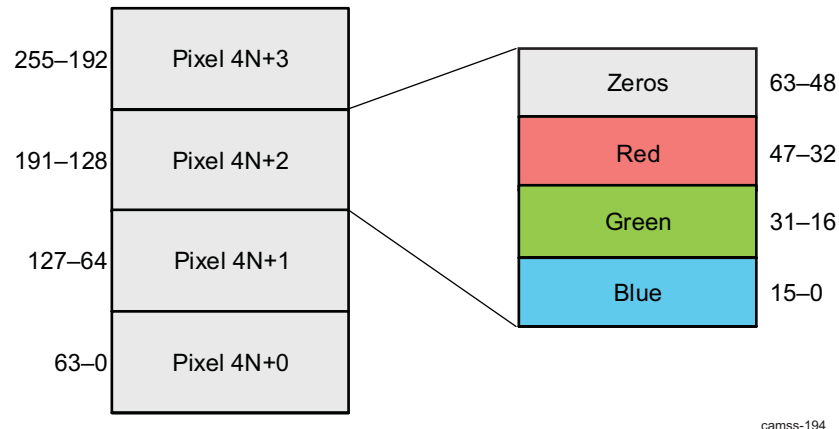

Figure 8-158. ISS ISP IPIPE Boxcar Operation (16 × 16 Block)

**Figure 8-159. ISS ISP IPIPE Boxcar Data Packing in SDRAM**

The right shift value is specified by the `IPIPE_BOX_SHF` register, which has a range of 0 to 4. (The shift down is performed to fit the 20-bit accumulated value into 16-bit output.) For green signal processing, a divide-by-two operation rounds off the least-significant bit (LSB).

### 8.3.3.5 ISS ISP RSZ Functional Description

#### 8.3.3.5.1 ISS ISP RSZ Overview

The RSZ module rescales images into various sizes ranging from x1/4096 scale-down to x16 scale-up. It also works in conjunction with the rotational engine (ROT) in SIMCOP for rotating images. The RSZ data slave interfaces support a parallel video port (VP). The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same.

The RSZ module has the following capabilities:

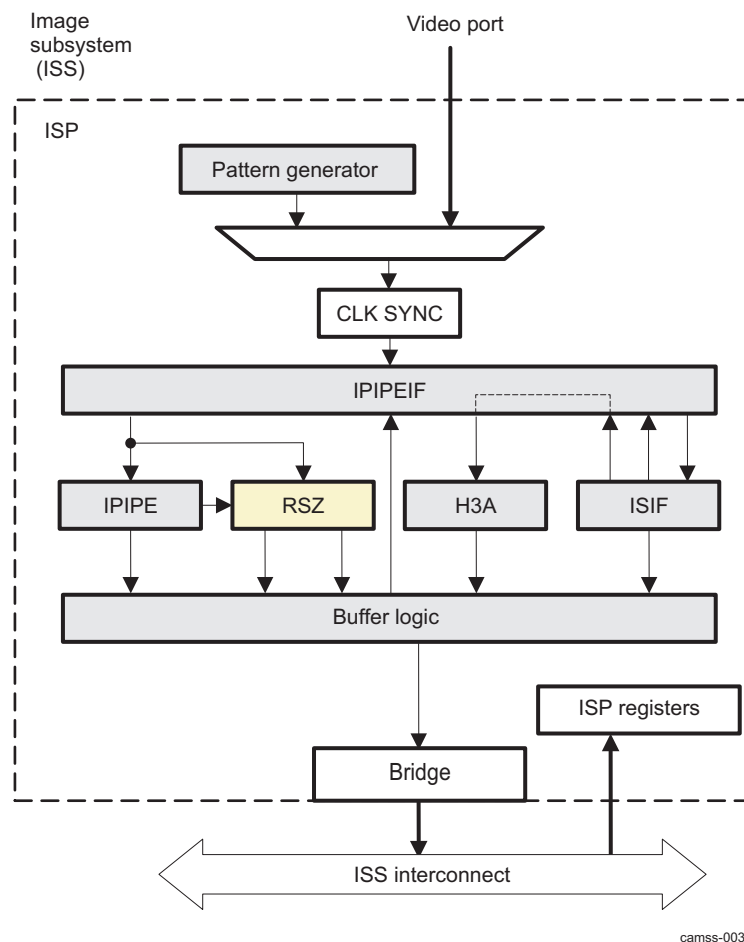

- Input/output data formats:
  - Common input data for the two resizers
  - Independent output data formats for the two resizers
  - Supports YUV4:2:2 input and then supports YUV4:2:2/YUV4:2:0 or RGB5:6:5/ARGB32 output.
    - Output rates up to 200 MPix/s for YUV4:2:2/YUV4:2:0 or RGB5:6:5 output
    - Output rates up to 160 MPix/s for ARGB32 output
  - Supports YUV4:2:0 input data and then supports only YUV4:2:0
    - YUV4:2:0 input format not supported natively
      - Two passes required: luma followed by chroma or vice versa
        - Input and output rates up to 100 MPix/s in this configuration (YUV4:2:0)
      - Only supported from memory to memory
  - Supports RAW Bayer input and RAW Bayer output
    - RAW format invariant. Takes whichever RAW format at the input and writes it out unmodified: 16 bits are read, 16 bits are written out.
    - No resizing can take place on RAW data.
- Resizer capabilities:
  - Input image cropping
    - Common for the two resizer engines: Same input data before and after cropping
    - Supported on YUV4:2:2 and RAW data formats
    - Supported on pass-through mode data path
    - Supported on bypass mode data path

- Dual resizer engines: RSZ-A and RSZ-B
  - Up to x20 upsampling and x1/4096 downsampling on both engines
  - Up to 200-MHz pixel throughput on both resizer engines
  - Programmable data rate control to smooth the peak memory bandwidth
- RSZ-A
  - Horizontal resolution of up to 8K pixels on RSZ-A.
- RSZ-B
  - Horizontal resolution of up to 8K pixels on resizer RSZ-B
- Independent Y and Cb/Cr phases on horizontal and vertical axis
  - Enables to take care of different YUV4:2:0 phases used in different video formats
  - Enables frame division mode: Images can be stitched together with the right phase.
- Rescaling: two modes supported
  - Normal mode for upscale and downscale: Higher flexibility but lower downscale quality
  - Downscale mode for downscale only: Lower flexibility but higher downscale quality
- Filtering: two modes supported
  - Independent settings for the horizontal and vertical directions
  - 3-tap low pass filter with 2-tap linear interpolation
  - 4-tap cubic interpolation
- Flip support of the output image
  - Horizontal flip
  - Vertical flip
- Pixel duplication on the top/bottom, left/right sides
  - Avoids losing pixels at the image boundaries because of the filtering
- Support pass-through and bypass modes: Resizer engines bypassed
  - Pass-through mode
    - RAW and YUV4:2:2 data support
    - Lower power consumption mode to transfer data to memory
    - Can transfer images larger than 8K pixels to memory
  - Bypass mode
    - RAW and YUV4:2:2 data support
    - Input buffer used. Can benefit from additional buffering in case the BL module memory is not big enough and back pressure occurs.
- Slave data interface: VP interface
  - Two VP interfaces: The programming model selects which VP is used to input data to the RSZ module. Both VPs cannot be active simultaneously.
    - VP 1: Typically connected to the IPIPE module.
    - VP 2: Typically connected to the IPIPEIF module.
  - Up to 200-MHz pixel clock
- Master data interface:
  - Two interfaces to the BL module
    - Up to 200 MHz
    - 32-bit wide, 32-byte long requests
    - Accesses are aligned on 32-byte boundaries
    - Used to transfer data to memory
    - Each interface is dedicated to a single output image.
  - Addressing modes

- Linear
- Circular
- Configuration interface:
  - Up to 100 MHz
  - 32-bit wide
  - Used to configure the resizer registers
- Power management:
  - Independent clock domains for the two resizers
    - Each resizer engine can be gated off separately
- Error management:
  - FIFO overflow detection on the input buffers

Figure 8-160 show the RSZ module connections to other submodules of the ISP.

**Figure 8-160. ISS ISP RSZ High-Level Diagram**

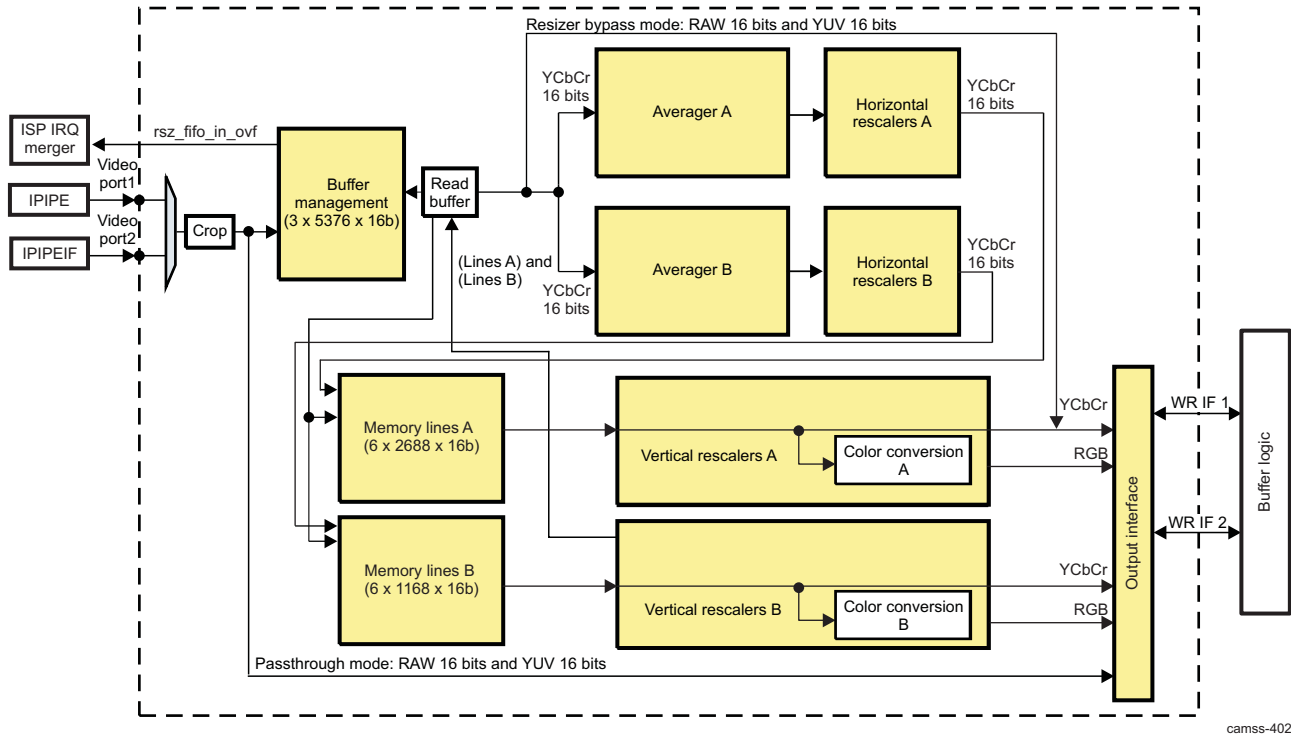

### 8.3.3.5.2 ISS ISP RSZ Top-Level Block Diagram

Figure 8-161 is the top-level block diagram of the RSZ module. The RSZ module comprises the following submodules: cropping, input data buffering, data requestor, averager, data saturation, and resizer Interpolation (comprised of horizontal rescaler, vertical rescaler, color conversion, and output interface) (see the following sections for more information).

The RSZ module comprises two independent resizer engines with the same capabilities (except for the memory line size). The input data can come from VP 1 or VP 2. Software must determine and control which interface is selected.

The RSZ module includes one VBUSP slave port, which is used to control the RSZ registers. It also includes two MTC master ports, which are used to pass the pixels to the BL. The BL in turn creates the burst requests to the memory subsystem (see [Section 8.3.3.5.3, ISS ISP RSZ Interfaces](#)).

**Figure 8-161. ISS ISP RSZ Top-Level Block Diagram**

camss-402

### 8.3.3.5.3 ISS ISP RSZ Interfaces

The RSZ module has the following data interfaces:

- One 32-bit read/write point-to-point pending VBUSP interface
- Two slave VP interfaces for transport YUV and RAW data
- TWO MTC interfaces to BL for RZA A and RZA B, with only write capabilities

#### 8.3.3.5.3.1 ISS ISP RSZ VBUSP interface

The VBUSP interface is a 32-bit read/write capable interface. The VBUSP interface must be programmed in a way that back-to-back requests are possible for read and write. The [RSZ\\_GCK\\_MMR\[0\]](#) MMR bit enables the memory register access from the VBUSP interface to enable transfer and signal such as MMR request, direction, enable write/read data can be enabled.

#### 8.3.3.5.3.2 ISS ISP RSZ Video Port Interfaces

The VP interfaces are slave interfaces; one is connected to IPIPE, and the other to IPIPEIF. These interfaces are for data transfer. [Table 8-322](#) lists the format supported across IPIPE/IPIPEIF and RSZ. Signals coming from IPIPE and IPIPEIF can be write-enable signals. The [RSZ\\_SRC\\_MODE\[1\]](#) WRT bit is set whether or not the write enable signals are considered. This is a line-valid qualifier. This signal is sampled on the rising edge of HD, and the value is used for the full line.

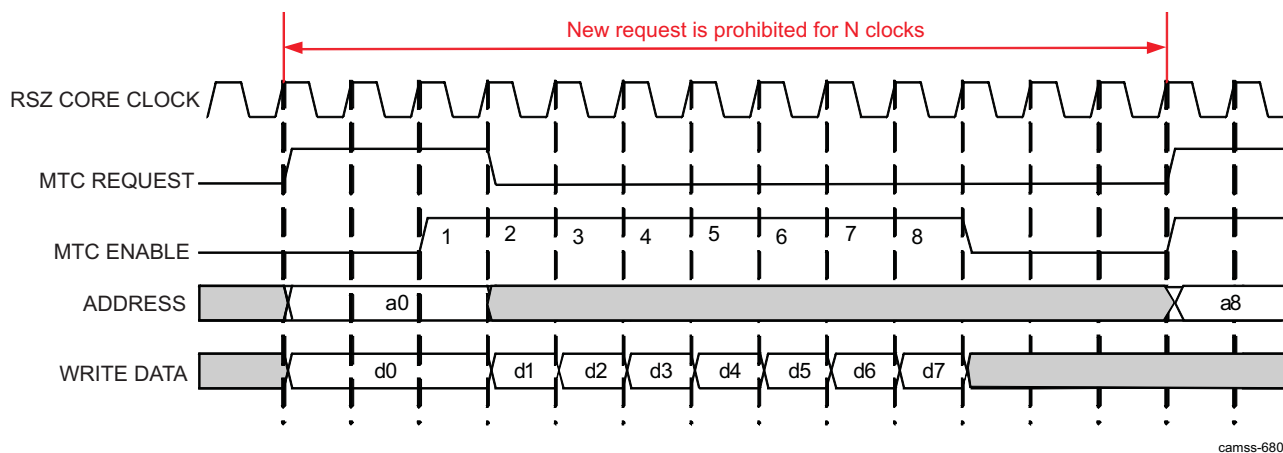

**Table 8-322. ISS ISP RSZ VP Supported Formats**

	VP Signals: From IPIPE and IPIPEIF Modules (dat[15:0] Register)															
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RAW16	R15	R14	R13	R12	R11	R10	R9	R8	R7	R6	R5	R4	R3	R2	R1	R0
YUV4:2: 2 16 bits	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Cb7 Cr7	Cb6 Cr6	Cb5 Cr5	Cb4 Cr4	Cb3 Cr3	Cb2 Cr2	Cb1 Cr1	Cb0 Cr0
YUV4:2: 0 Y data	Y7	Y6	Y5	Y4	Y3	Y2	Y1	Y0	Low	Low	Low	Low	Low	Low	Low	Low
YUV4:2: 0 Cb/Cr data	Low	Low	Low	Low	Low	Low	Low	Low	Cb7 Cr7	Cb6 Cr6	Cb5 Cr5	Cb4 Cr4	Cb3 Cr3	Cb2 Cr2	Cb1 Cr1	Cb0 Cr0

**NOTE:** The formats are set from the IPIPE and IPIPEIF registers. For more information, see [Section 8.3.3.4](#) and [Section 8.3.3.3](#).

### 8.3.3.5.3.3 ISS ISP RSZ MTC interfaces

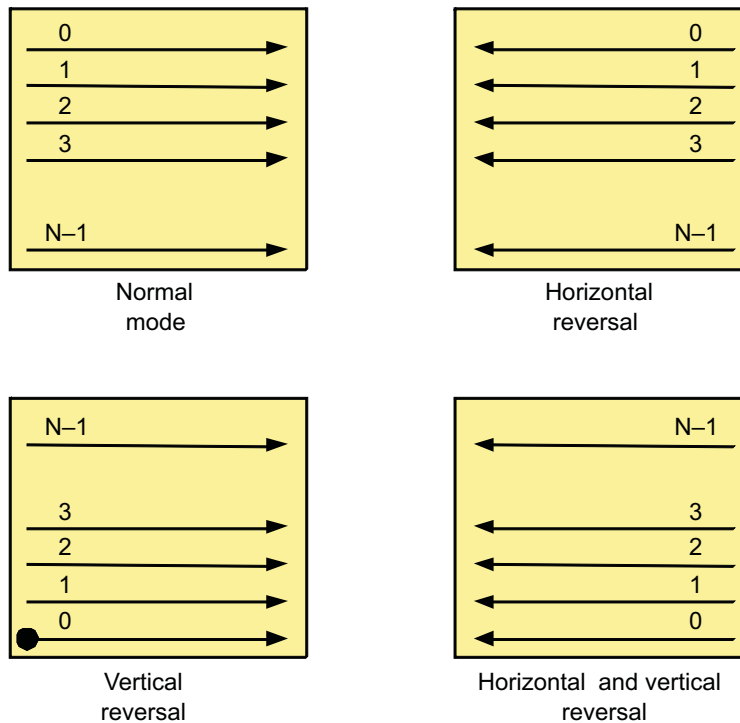

The RSZ module includes two write-only MTC interfaces. Their implementation enables passing a maximum of eight 32-byte requests in ten clock cycles. The RSZ must be programmed to obtain smooth and average bandwidth to buffer logic module by setting a minimum interval between two successive requests (set the `RSZ_DMA_RZA[15:0]` RZA and `RSZ_DMA_RZB[15:0]` RZB bit fields for the A and B resizers as appropriate). This setting is not expected to be dynamic. It can be fixed setting from request to request and frame to frame. When the bandwidth is set appropriately, between the first valid translated pixel and the EOF signal sent to buffer logic, the `RSZ_DMA_STA[0]` STATUS bit can be seen, and it is high if the transfer over the MTC interfaces is active. [Figure 8-162](#) shows how `RSZ_DMA_RZx` for resizers A and B affects the MTC data request generator.

**Figure 8-162. ISS ISP RSZ MTC DMA Bandwidth Control**

[Figure 8-163](#) shows the pixel order in memory written by the MTC. The arrows do not represent the order in which data is written. Data are always written from left to right, whether horizontal reversal is enabled or not.

camss-680

**Figure 8-163. ISS ISP RSZ MTC Image Data Storage Pixel Order**

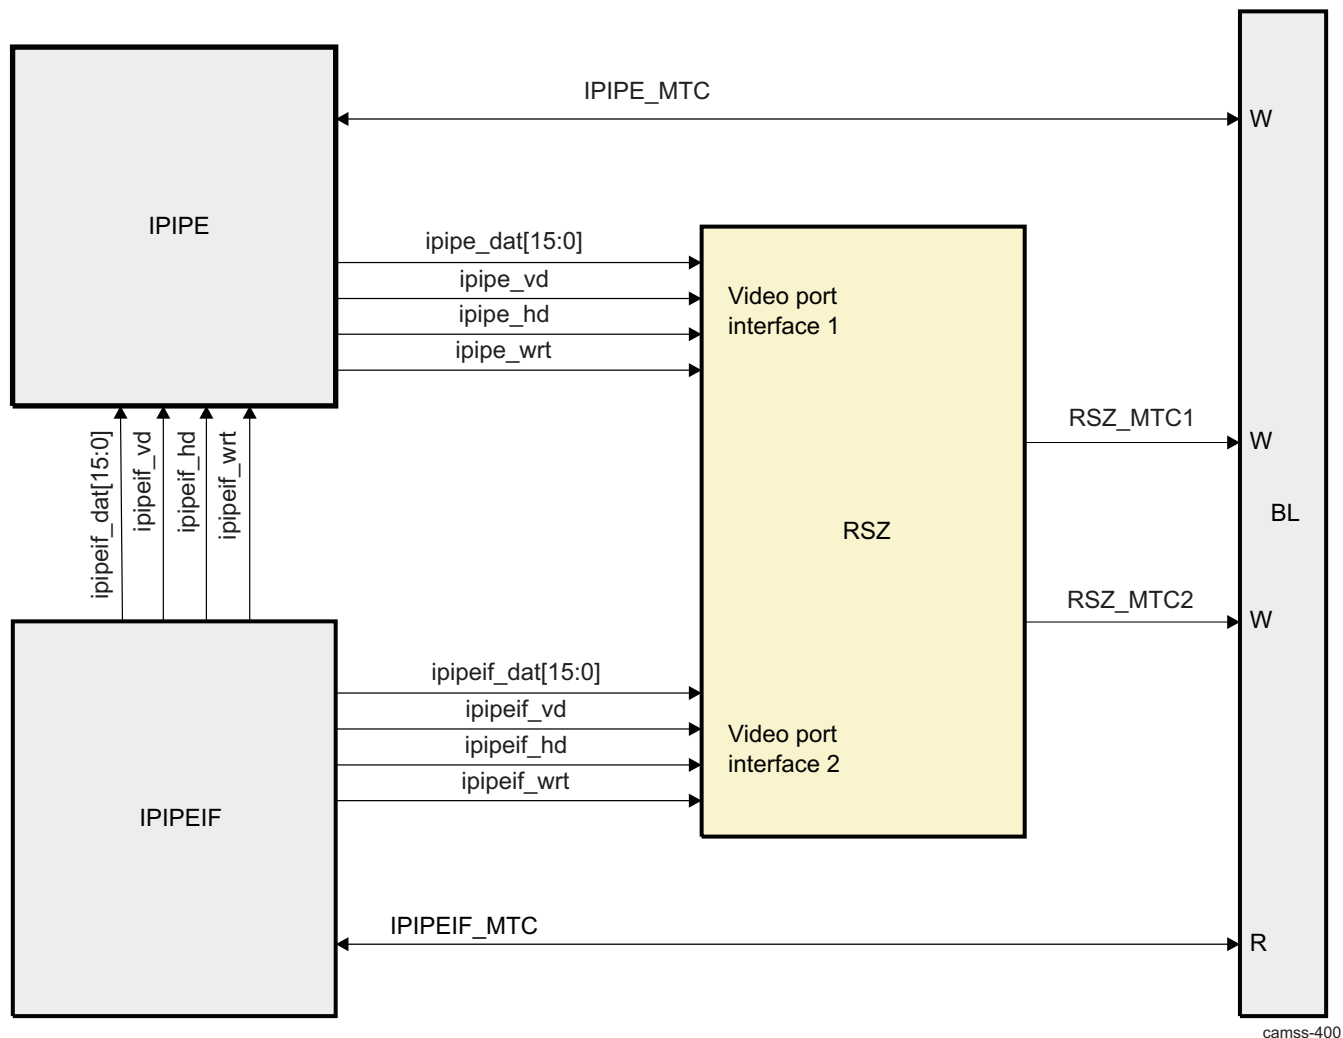

camss-684

The RSZ MTC interfaces can be stalled by the input MTC STALL signal. The assertion of the MTC STALL signal is a result of a hardware mechanism that is monitoring the CBUFF module to prevent its overflow. When this signal is asserted, the current 32-byte MTC request is finished and then the RSZ MTC output ports are stalled. For details on the output ports, see [Section 8.3.3.5.7, ISS ISP RSZ Output Interface](#).

#### 8.3.3.5.4 ISS ISP RSZ Integration

[Figure 8-164](#) shows how the VP and interfaces of the RSZ module are connected to surrounding modules at the ISP level. The RSZ module gets data from the IPIPEIF module or IPIPE module.

**Figure 8-164. ISS ISP RSZ Typical Module Integration: High-Level Summary**

The following constraints apply to the RSZ module:

- The data coming from the IPIPEIF module can be RAW or YUV4:2:2 data. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 2. It is possible to bypass the RSZ engine if YUV4:2:2 data is sent but rescaling is not needed (bypass mode).
- The data coming from the IPIPE module can be RAW or YUV4:2:2 data. Eventually, YUV4:2:0 data can be sent through this path, but the data must be sent in two passes. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 1. It is possible to bypass the RSZ engine if YUV4:2:2 data is sent but rescaling is not needed (bypass mode).

VP 2 provides a way to bypass the IPIPE module when YUV4:2:2 data is received from the images sensor or when YUV4:2:2 is read back from memory with the CCP2 RX or ISIF module.

[Table 8-323](#) summarizes the different RSZ configuration possibilities as a function of the input data format.

**Table 8-323. ISS ISP RSZ Data Flow vs. Input Data Format Constraints**

VP 1 Data Format	VP 2 Data Format	RSZ-A Configuration	RSZ-B Configuration	Comments
RAW	N/A	Disabled	Disabled	RSZ module in pass-through mode or bypass mode

**Table 8-323. ISS ISP RSZ Data Flow vs. Input Data Format Constraints (continued)**

VP 1 Data Format	VP 2 Data Format	RSZ-A Configuration	RSZ-B Configuration	Comments
N/A	RAW	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
YUV4:2:2	N/A	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
YUV4:2:2	N/A	Enabled	Disabled	One output image
YUV4:2:2	N/A	Disabled	Enabled	One output image
YUV4:2:2	N/A	Enabled	Enabled	Two output images
N/A	YUV4:2:2	Disabled	Disabled	RSZ module in pass-through mode or bypass mode
N/A	YUV4:2:2	Enabled	Disabled	One output image
N/A	YUV4:2:2	Disabled	Enabled	One output image
N/A	YUV4:2:2	Enabled	Enabled	Two output images

### 8.3.3.5.5 ISS ISP RSZ Functional Description

To start up, the RSZ configuration can be set from the [RSZ\\_SYSCONFIG](#) register, which provides enabling the RSZ-A and RSZ-B clocks. The RSZ module does not have standalone reset and status check. Software reset must be done at the ISP level. Moreover, when enabled, the RSZ module can control the input data buffer, and when the `rsz_stall_input` signals are set from the [RSZ\\_IN\\_FIFO\\_CTRL](#) register, the RSZ module generates a stall signal that can be used by the master module sending data to the RSZ module when the data threshold is too high.

The [RSZ\\_SRC\\_EN\[0\]](#) EN bit starts the resizer processing. If the processing mode is set to one shot (one run and then turn off) from the [RSZ\\_SRC\\_MODE\[0\]](#) OST bit, the EN bit is cleared to 0.

The resizer can be configured to be bypassed in certain cases (see [Figure 8-164](#) for the module constraints) from the [RSZ\\_SRC\\_FMT0\[1\]](#) BYPASS bit. The data can be sent directly from here to the output interface (bypass mode) or imported to the module buffer, but not manipulated and sent to the output interface (pass-through mode). The master device sending data to the resizer can be switched between IPIPEIF and IPIPE using the [RSZ\\_SRC\\_FMT0\[0\]](#) SEL bit. The resizer understanding of the data input is set from the [RSZ\\_SRC\\_FMT1](#) register (for more information, see [Table 8-325](#)). The [RSZ\\_SEQ.VRVX](#) and [RSZ\\_SEQ.HRVX](#) registers can be set to flip the image horizontally or vertically, respectively (see [Figure 8-163](#)).

Depending on the mode to which the resizer is set, the core clock can be enabled from the [RSZ\\_GCK\\_SDR](#) register. [Table 8-324](#) summarizes the behavior of the module for the different settings.

**Table 8-324. ISS ISP RSZ Module Modes: Register Settings**

Configuration Number	RSZ_SRC_EN	RZA_EN	RZA_CLK_EN	RZB_EN	RZB_CLK_EN	RSZ_GCK_SDR_CORE	RSZ_SRC_FMT0.BYPASS	Comments
0	0	X	X	X	X	X	X	Data cannot go through the RSZ module. Interrupts are not issued.
1	1	0	X	0	X	1	0	Resizer A is disabled. Resizer B is disabled.
								It is best to have <code>RZA_EN = RZB_EN = 0</code> to save power, but <code>RZA_EN = RZB_EN = 1</code> is also supported.
								This configuration is supported but does not make sense because data cannot go through the module.
2	1	1	1	0	X	1	0	Resizer A is enabled. Resizer B is disabled.

**Table 8-324. ISS ISP RSZ Module Modes: Register Settings (continued)**

								It is best to have <a href="#">RZB_EN</a> = 0 to save power, but <a href="#">RZB_EN</a> =1 is supported as well.
3	1	0	X	1	1	1	0	Resizer A is disabled. Resizer B is enabled.
								It is best to have <a href="#">RZA_EN</a> = 0 to save power, but <a href="#">RZA_EN</a> = 1 is also supported.
4	1	1	1	1	1	1	0	Resizer A is enabled. Resizer B is enabled.
5	1	X	X	X	X	0	0	Bypass mode is enabled. Resizer core functional clock is disabled.
6	1	X	X	X	X	0	1	Pass-through mode enabled. Resizer core functional clock is disabled.
7	1	X	X	X	X	1	1	Pass-through mode is enabled. Resizer core functional clock is enabled.
								Not a preferred configuration. Configuration (6) saves power.

**Table 8-325. ISS ISP RSZ Module Input Control: Register Settings**

<a href="#">RSZ_SRC_FMT1.IN420</a>	<a href="#">RSZ_SRC_FMT1.COL</a>	Comments
0	X	YUV4:2:2 input. Chrominance is cosited.
1	0	YUV4:2:0 input. Valid data is Y, C is dummy. On the VP, YUV4:2:2 data is always assumed.
1	1	YUV4:2:0 input. Valid data is C, Y is dummy. On the VP, YUV4:2:2 data is always assumed.

The [RSZ\\_YUV\\_PHS\[0\]](#) POS bit sets the chrominance output. The RSZ module does not change the relative position of the chroma samples versus the luma samples between the input and output, and the chroma position at the output of the IPIPE module and at the output of the RSZ module must be identical. In other words, [RSZ\\_YUV\\_PHS.POS](#) = [IPIPE\\_YUV\\_PHS.POS](#).

Settings are common for both resizer engines inside the RSZ module. Each engine (RZA or RZB) can be enabled from the [RZx\\_EN](#) register: select the mode from [RZx\\_MODE](#), and select the input and output in the YUV color scheme from the [RZx\\_420](#) register (valid only if YUV 4:2:2 is the input set from [RSZ\\_SRC\\_FMT1.IN420](#)). [Table 8-326](#) summarizes the combination of settings available in the [RZx\\_420](#) register.

**Table 8-326. ISS ISP RSZ-A/RSZ-B Output Format Selection**

<a href="#">RZx_420.YEN</a>	<a href="#">RZx_420.CEN</a>	Comments
0	0	Input is YUV4:2:2. Output is YUV4:2:2 if <a href="#">RZX_RGB_EN</a> = 0 and RGB if <a href="#">RZB_RGB_EN</a> = 1.
0	1	Input is YUV4:2:2. Output is the chroma of YUV4:2:0. <a href="#">RZX_RGB_EN</a> is ignored. Must be used to rescale YUV4:2:0 data: 1st/2nd pass
1	0	Input is YUV4:2:2. Output is the luma of YUV4:2:0. <a href="#">RZX_RGB_EN</a> is ignored. Must be used to rescale YUV4:2:0 data: 2nd/1st pass
1	1	Input is YUV4:2:2. Output is YUV4:2:0. <a href="#">RZX_RGB_EN</a> is ignored.

### 8.3.3.5.1 ISS ISP RSZ Operating Modes

The RSZ module offers two basic rescaling modes. These modes are not built-in but are particular configurations, which means that other hybrid modes can be programmed. The normal mode provides more flexibility (the rescale ratio granularity is smaller) than downscale mode, but downscale mode produces better image quality (averager performs anti-aliasing):

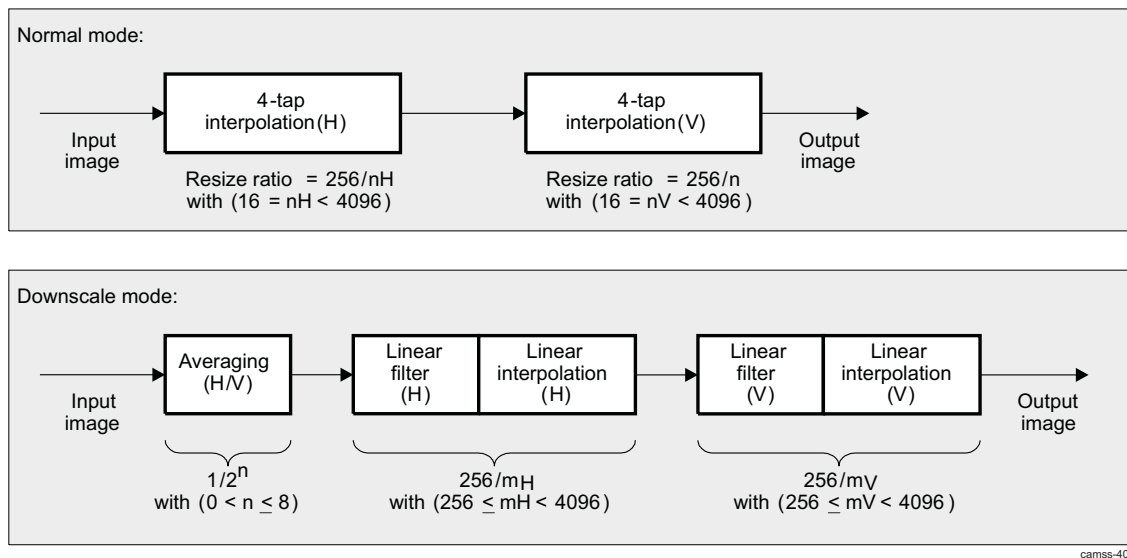

- Normal mode: The scaling process is carried out using interpolation with a 4-tap filter. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The user controls the type of interpolation that is used. The possible rescale ratios range from 1/16x to 20x.
- Downscale mode: The scaling process is the same as for normal mode, but an averaging function is placed before. It enables reaching much higher reduction factors while avoiding anti-aliasing artifacts. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The possible rescale ratios range from 1/4096x to 1x.

**NOTE:** The selection of the mode is independent for each resizer engine. One resizer engine can be configured in normal mode, while another is configured in downscale mode.

The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same. The RSZ output image sizes are limited to `RSZ_GNC[0:12]` `RSZA_MEM_LINE_SIZE` pixels/line for RSZ-A (5376 pixels/line) and `RSZB_MEM_LINE_SIZE[16:28]` for RSZ-B (2336 pixels/line).

Figure 8-165 shows the RSZ operating modes. Nothing prevents the use of linear interpolation in normal mode or bicubic interpolation in downscale mode; similarly, it is possible to mix the interpolation modes for horizontal and vertical filtering. This is fully programmable.

**Figure 8-165. ISS ISP RSZ Operating Modes**

camss-401

**8.3.3.5.5.1 ISS ISP RSZ Operating Modes and Maximum Input Clock**

The maximum output pixel clock on both resizers is 200 MHz (100 percent optimal power performance [OPP]); that is, a pixel throughput of 200 MPix/s. Moreover, hardware takes care of the following constraints:

- When both resizer engines are configured to perform downscaling, there is no particular constraint on the VP pixel clock. The VP pixel clock can be as high as 200 MHz.
- When one resizer engine is configured to perform upscaling and the second resizer engine is configured to perform downscaling, the VP pixel clock must be limited. The VP must be lower than:

$$\text{clk\_pix} \leq (200 \text{ MHz} / (\text{Vertical Upscale Ratio} * \text{Horizontal Upscale Ratio})) \tag{5}$$

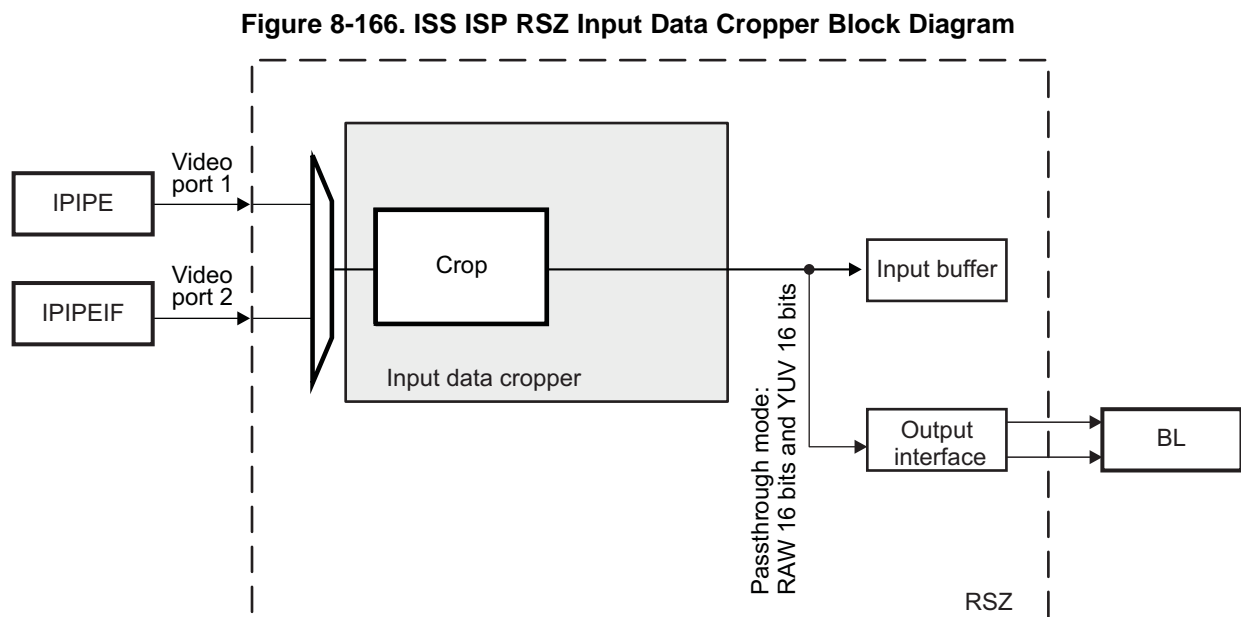

For example, if a 4x upscale ratio happens horizontally and vertically, then the input pixel clock must be lower than  $200 / (4 * 4) = 12.5$  MHz.

It is the reason why it is not possible to perform digital zoom upscaling on the fly. It is necessary to acquire the pixels to memory first and to read them back at a pace that does not exceed the previously discussed constraints. At the ISS level, data can be read back from memory from the CCP2 RX or ISIF module.

- When the two resizer engines are configured to perform upscaling, the VP pixel clock must be limited. In that case, the VP frequency is limited by the resizer engine having the larger rescale ratios.

### 8.3.3.5.5.2 ISS ISP RSZ Input Data Cropper

The data coming from the VPs into the RSZ module can be cropped: this applies to RAW and YUV4:2:2 data. It is mandatory to crop the data as early as possible in the RSZ processing pipeline to reduce power consumption. It is mandatory to crop the data before storing it in the input data buffer. Figure 8-166 is the block diagram of the RSZ input data cropper.

camss-708

The input data are in YUV4:2:2 interleaved format or RAW format.

For YUV4:2:2 format, the data come as Cb0, Y0, Cr0, Y1, Cb2, Y2, Cr2, Y3, etc. Y denotes the luma component value and Cb/Cr denotes the chroma component values. There are as many Y components as Cb/Cr components per line.

Figure 8-167 shows input data cropping. Only the cropped data is stored in the input data buffer. The names used in the figure correspond to the register names. If no cropping is desired, the [RSZ\\_SRC\\_HPS](#) and [RSZ\\_SRC\\_VPS](#) registers, which set the horizontal and vertical positions, must be set to 0; the start size from the [RSZ\\_SRC\\_HSZ](#) register must be set to the input image width minus 1, and the [RSZ\\_SRC\\_VSZ](#) register must be set to the input image height minus 1. These are common settings for both resize engines inside the RESIZER. After setting, more flexibility is present through the [RZx\\_i\\_VPS](#) and [RZx\\_i\\_HPS](#) registers for vertical and horizontal positioning, respectively, of the input/output (where x = A or B, i = I or O).

---

**NOTE:** After the RSZ second-level cropping (defined by the [RZA\\_I\\_VPS](#) and the [RZB\\_I\\_VPS](#) register settings), the height of the image frame must be two lines or larger. A one-line image is not allowed.

---

Depending on the input data format, different constraints apply to the registers that set the cropping parameters:

- For YUV4:2:2 format, the vertical start positions of the cropped frame can be even or odd. However, the horizontal start position must be even: the reason is to always start with the same pattern: Cb<sub>2n</sub>, Y<sub>2n</sub>, Cr<sub>2n</sub>, Y<sub>2n+1</sub>,... For the same reason, the horizontal size of the cropped frame ([RSZ\\_SRC\\_HSZ](#) + 1) must be an even number. Finally, the vertical size of the cropped frame can be odd or even.
- For RAW format, the vertical start position of the cropped frame can be even or odd. The vertical size can be even or odd. The horizontal resolution must be even.

These features and constraints are common for both resizer engines inside the resizer module. Figure 8-167 shows the input data cropping.

**Figure 8-167. ISS ISP RSZ Input Data Cropping**

camss-403

### 8.3.3.5.5.3 ISS ISP RSZ Averager

#### 8.3.3.5.5.3.1 ISS ISP RSZ Use Cases

The two RSZ engines can have independent averager settings:

- Both resizers can use it.
- One resizer can bypass it and the other can use it.
- Both resizers can bypass it.

#### 8.3.3.5.5.3.2 ISS ISP RSZ Memory Utilization

Vertical averaging requires memory to perform pixel data accumulation. It shares the vertical memory lines that are used for vertical filtering: this is the reason why the vertical memory lines are organized as two banks of half lines.

- The averagers output lines that are at most half the size of the input image in one memory bank.
- The horizontal resizers write their output data in the second memory banks.

Figure 8-168 shows the use of memory when the averager is enabled or disabled.

Figure 8-168. ISS ISP RSZ Averager Memory Utilization

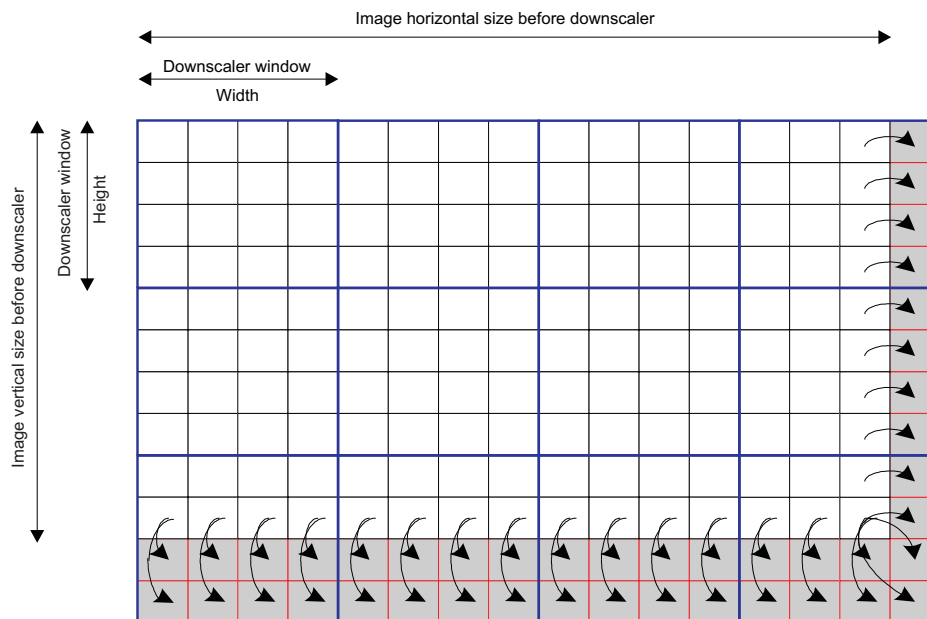

camss-407

### 8.3.3.5.5.3.3 ISS ISP RSZ Border Conditions

Figure 8-169 shows the averager behavior for border conditions. If the input image is not big enough, border duplication must occur.

Figure 8-169. ISS ISP RSZ Averager Border Conditions

camss-408

Downscaling is enabled from the RZi\_DWN\_EN register. Moreover, the vertical averaging size is set by the RZA\_DWN\_AV[3:5] V bit field. The actual downscale ratio is given by  $1/2^{(RZA\_DWN\_AV[3:5] V + 1)}$ . The range is from 1/2 to 1/256 in power of two. The horizontal averaging size is set by the RZA\_DWN\_AV[0:2] H bit field. The actual downscale ratio is given by  $1/2^{(RZA\_DWN\_AV[0:2] H + 1)}$ . The equations are the same for RSZ-B. The range goes from 1/2 to 1/256 in power of 2.

8.3.3.5.5.4 ISS ISP RSZ Interpolation

Figure 8-170 shows the basic interpolation method used in the RESIZER module. The following assumptions are made:

- The distance between each input pixel is 1.
- The magnification ration is given by  $256/N$  and  $p/256$  is the initial phase of the output data.

The output pixels are also evenly spaced. The distance between each output pixel is given by  $N/256$ . In the example in Figure 8-170,  $N$  is greater than 256. The position of the  $n^{th}$  output pixel is given by  $(n \times N + p) / 256$ .

Figure 8-170. ISS ISP RSZ Basic Interpolation Method

camss-682

Assuming the intensity of input pixels is  $i_0, i_1, i_2,$  etc. and the resized (output) pixels are  $o_0, o_1, o_2,$  etc., the  $n^{th}$  output pixel ( $o_n$ ) is determined using the nearest 4 input pixels as follows:

$$o_n = h(1+d) \times i_1 + h(d) \times i_m + h(d-1) \times i_{m+1} + h(d-2) \times i_{m+2}$$

In the previous equation  $h(x)$  is the interpolation main function. The RESIZER module supports linear and bicubic convolution interpolation functions.

Figure 8-171 shows the interpolation principle at the  $n^{th}$  output pixel ( $o_n$ ) at position  $x_n$ . Furthermore, the  $m$  and  $d$  parameters are as follows:

$$m = \text{floor}((n \times N + p) / 256) \text{ and } d = ((n \times N + p) / 256) - m$$

**Figure 8-171. ISS ISP RSZ Interpolation Filtering**

camss-683

For each resizer (RSZ-A or RSZ-B), and for chrominance and luminance, the interpolation method for vertical interpolation can be a 2-tap linear interpolation or a 4-tap cubic convolution (default) method. The choice is made in RZi\_V\_TYP[0] Y for luminance and RZi\_V\_TYP[1] C for chrominance, where  $i = A$  or  $B$  and is the resizer number. It is similar for horizontal interpolation from RZi\_H\_TYP[0] Y for luminance and RZi\_H\_TYP[1] C for chrominance, where  $i = A$  or  $B$  and is the resizer number.

#### 8.3.3.5.5.4.1 ISS ISP RSZ Liner Interpolation Input Data

Before data interpolation, a low pass filtering (LPF) operation is required on the input data. The following equation gives the LPF function. The equation is evaluated at pixel position  $d_i$ , but neighbor pixels  $d_{i-1}$  and  $d_{i+1}$  are required. The gain value  $g$  is set up by the register RZi\_V\_LPF and RZi\_H\_LPF. Different gains are possible horizontally and vertically as well as for Luma and Chroma.

$$LPF_g(d_{i-1}, d_i, d_{i+1}) = d_i + g \times (d_{i-1} - 2d_{i+1} + d_{i+2}) / 128$$

#### 8.3.3.5.5.4.1.1 ISS ISP RSZ Cubic Convolution Mode

The input data is not modified in bicubic mode. Basically, the input is equal to the output.

#### 8.3.3.5.5.4.1.2 ISS ISP RSZ Phase Settings

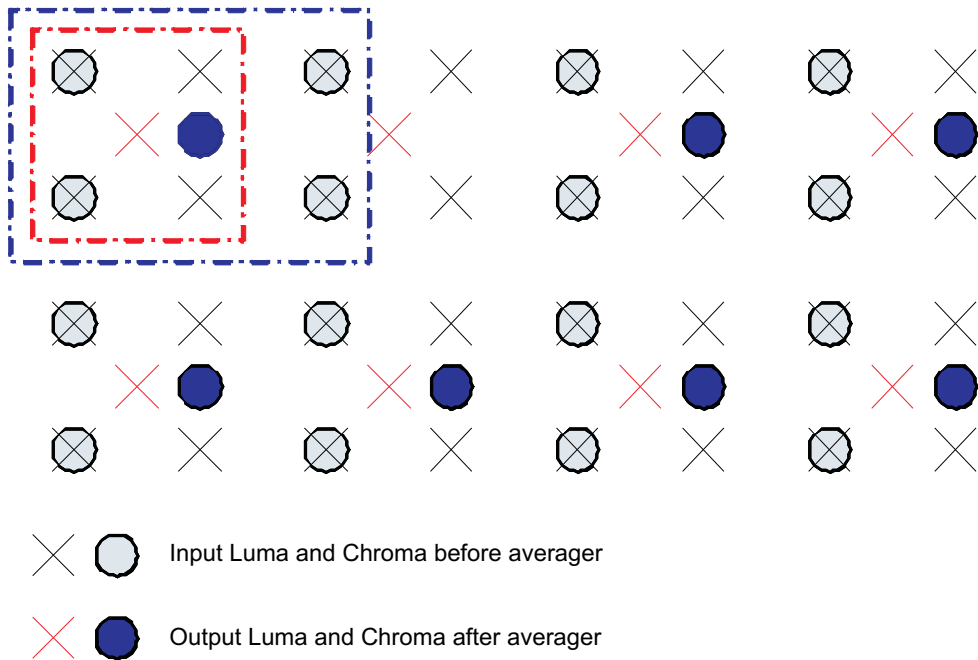

The initial value for the phase value for vertical resizing is set by the RZi\_V\_PHS\_Y for luminance and RZi\_V\_PHS\_C for chrominance. These values are in the U14Q8 fractional format (values in the range [0 – 63.996]). When YUV4:2:2 data are output, the phase value for Luma and Chroma must be aligned; that is, RZi\_V\_PHS\_Y = RZi\_V\_PHS\_C.

The following constraint equation applies:  $|RZi_V_PHS_Y - RZx_V_PHS_C| \leq RZi_V_DIF$ . This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two Luma pixels. The absolute value is used; therefore, the initial Luma phase can be greater than the initial Chroma phase or vice versa. As a reminder, the distance between two output pixels for Luma is given by RZi\_V\_DIF.

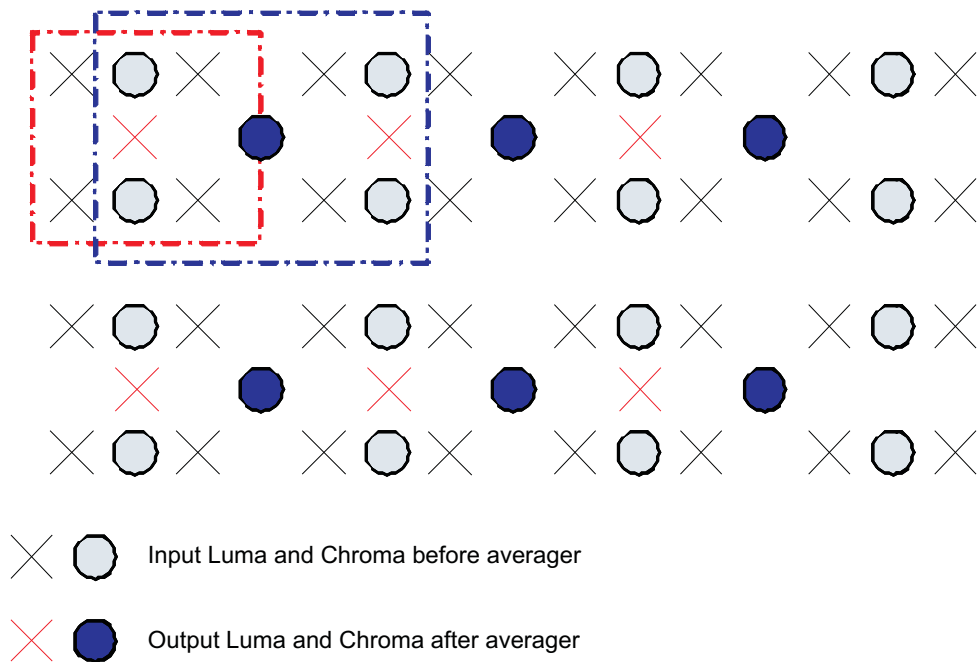

The initial value for the phase value for horizontal resizing is set by the RZi\_H\_PHS bit field. The RZi\_H\_PHS\_ADJ register enables adjusting the horizontal phase for the Luma component when averaging is enabled (the averager disrupts the relative sampling point between luminance and chrominance when YUV4:2:2 cosited data is input). The relative phase between Luma and Chroma is different before and after the horizontal averager. The vertical phase is not affected by the averager. [Figure 8-172](#) shows the effect of the averager on the phases. RZi\_H\_PHS\_ADJ is expected to be equal to zero if the averager is disabled.

**Figure 8-172. ISS ISP RSZ-A/RSZ-B Phase Averager Effect**

Input Chroma is co-sited: relative input I/O phases btw Y and UV are different, correction is needed.

Input Chroma is centered: relative input I/O phases btw Y and UV are identical, no correction is needed.

camss-685

**8.3.3.5.5 ISS ISP RSZ Data Saturator**

After vertical rescaling and before color conversion, the output data is saturated (clipped) to programmable values that are given by the following registers:

- [RSZ\\_YUV\\_Y\\_MIN](#)
- [RSZ\\_YUV\\_Y\\_MAX](#)
- [RSZ\\_YUV\\_C\\_MIN](#)
- [RSZ\\_YUV\\_C\\_MAX](#)

The maximum Y value is set up with the [RSZ\\_YUV\\_Y\\_MAX](#) register. If the Input Y value is greater than the MAX value, it is clipped to MAX.

The minimum Y value is set up with the [RSZ\\_YUV\\_Y\\_MIN](#) register. If the Input Y value is smaller than the MIN value, it is clipped to MIN.

The maximum Cb/Cr value is set up with the [RSZ\\_YUV\\_C\\_MAX](#) register. If the Input Cb/Cr value is greater than the MAX value, it is clipped to MAX.

The minimum Cb/Cr value is set up with the [RSZ\\_YUV\\_C\\_MIN](#) register. If the Input Cb/Cr value is smaller than the MIN value, it is clipped to MIN.

### 8.3.3.5.5.6 ISS ISP RSZ Color Convertor

As mentioned previously, the resizer can support RAW, YUV4:2:0, and YUV4:2:2 formats. The resizer engines can also support RGB output: RGB5:6:5 and ARGB32.

The RGB5:6:5 data is 16 bits wide and consists of 5 bits for red, 6 bits for green, and 5 bits for blue.

The following table shows the way RGB5:6:5 is stored to memory. This data format is compatible with the display controller. Only the little-endian memory representation is supported.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R1					G1						B1					R0				G0			B0								

The ARGB32 data is 32 bits wide and consists of 8 bits for alpha, 8 bits for red, 8 bits for green, and 8 bits for blue. The alpha value is global and is set for the entire frame; registers control the alpha value: the RZx\_RGB\_BLD register controls the alpha values of resizer A and resizer B.

The following table shows the way ARGB32 is stored to memory. This data format is compatible with the display controller. This representation is endianness invariant: it is the same for little endian and big endian.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
A								R								G								B							

The RGB output is enabled by setting the RZx\_RGB\_EN[0] RGB\_EN bit to 1.

The RGB format is set by the RZx\_RGB\_TYP[0] TYP bit (0 for ARGB32 format and 1 for RGB5:6:5).

To handle the horizontal border conditions, the leftmost Chroma sample or the right-most Chroma sample is duplicated on the left or the right.

Software must make it possible to remove 2 pixels on the left and/or right to take care of the issues that Chroma duplication introduces on the borders. The RZx\_RGB\_TYP[1] MSK0 and RZx\_RGB\_TYP[2] MSK1 bits control this feature.

**Figure 8-173. ISS ISP RSZ Chroma Position and Upsampling**

### 8.3.3.5.5.7 ISS ISP RSZ Output Interface

The output interface receives the data generated by the two resizer engines and generates the addresses and the port requests to the BL module.

- The port 1 interface is dedicated to the RSZ-A module. If the RSZ module is set up in pass-through mode, then the data is output on the port 1 interface. This interface can transfer RAW, YUV4:2:2, YUV4:2:0 and RGB data
- The port 2 interface is dedicated to the RSZ-B module. This interface can transfer RAW, YUV4:2:2, YUV4:2:0 and RGB data.

The YUV4:2:0 data format is handled differently from the other formats because the output data are written at two different memory locations: luminance in one buffer and chrominance in a second buffer. For all other formats the data are written in the same buffer.

Each data format must be stored in memory in a dedicated manner, which is summarized in [Table 8-327](#).

**Table 8-327. ISS ISP RSZ Output Interface: Data Formats**

Output Format	Bytes per Pixel	Output Buffers per Image	Interface Supporting the Data Format
RAW	2	1	MTC port 1
YUV4:2:2	2 average	1	MTC port 1 port 2
YUV4:2:0	1.5 average	2	MTC port 1 port 2
RGB16	2	1	MTC port 1 port 2
ARGB32	4	1	MTC port 1 port 2

### 8.3.3.5.5.7.1 ISS ISP RSZ Circular Buffer

Figure 8-174 shows the parameters that are required to set up the circular buffers. As mentioned previously, there can be up to four circular buffers in case the two resizer engines are outputting YUV4:2:0 data.

The circular buffer management requires the following parameters (REZ-A or RSZ-B A or B, chrominance or luminance Y or C, low or high part of the address, L or H. Sets the base address of the circular buffer):

- Baseline address (BAD, in registers, where x is the resizer A or B, and i is Y or C)
- Start address (SAD, in RZx\_SDR\_i\_SAD\_j registers)
- Start pointer (PTR\_S, in RZx\_SDR\_i\_PTR\_S registers)
- End pointer (PTR\_E, in RZx\_SDR\_i\_PTR\_E registers)
- Line offset (OFT, in RZx\_SDR\_i\_OFT registers)

Circular Buffer Parameter	Register (for RSZ-A and RSZ-B)	Description
Baseline address	<a href="#">RZA_SDR_Y_BAD_H</a> <a href="#">RZA_SDR_Y_BAD_L</a> <a href="#">RZA_SDR_C_BAD_H</a> <a href="#">RZA_SDR_C_BAD_L</a> <a href="#">RZB_SDR_Y_BAD_H</a> <a href="#">RZB_SDR_Y_BAD_L</a> <a href="#">RZB_SDR_C_BAD_H</a> <a href="#">RZB_SDR_C_BAD_L</a>	Sets the base address of the circular buffer
Start address	<a href="#">RZA_SDR_Y_SAD_H</a> <a href="#">RZA_SDR_Y_SAD_L</a> <a href="#">RZA_SDR_C_SAD_H</a> <a href="#">RZA_SDR_C_SAD_L</a> <a href="#">RZB_SDR_Y_SAD_H</a> <a href="#">RZB_SDR_Y_SAD_L</a> <a href="#">RZB_SDR_C_SAD_H</a> <a href="#">RZB_SDR_C_SAD_L</a>	Sets the start address of the circular buffer. The first data output is written to this address. If the first line of a frame must be written at the beginning of the circular buffer memory, then SAD = BAD and PTR_S = 0.
Start pointer	<a href="#">RZA_SDR_Y_PTR_S</a> <a href="#">RZA_SDR_C_PTR_S</a> <a href="#">RZB_SDR_Y_PTR_S</a> <a href="#">RZB_SDR_C_PTR_S</a>	Sets the initial value of the circular buffer internal counter. It must be set up as PTR_S = (SAD - BAD)/OFT. PTR_S is expressed in the number of lines.
End pointer	<a href="#">RZA_SDR_Y_PTR_E</a> <a href="#">RZA_SDR_C_PTR_E</a> <a href="#">RZB_SDR_Y_PTR_E</a> <a href="#">RZB_SDR_C_PTR_E</a>	Sets the size of the circular buffer. PTR_E is expressed in the number of lines. The circular buffer can contain up to PTR_E lines.
Line offset	<a href="#">RZA_SDR_Y_OFT</a> <a href="#">RZA_SDR_C_OFT</a> <a href="#">RZB_SDR_Y_OFT</a> <a href="#">RZB_SDR_C_OFT</a>	This is the offset expressed in bytes between two lines in the circular buffer. Here: Line 0 = SAD, Line 1 = SAD + 1 x OFT, Line 2 = SAD + 2 x OFT, etc. OFT does not necessarily correspond to the size of a line in a frame; it can be bigger.

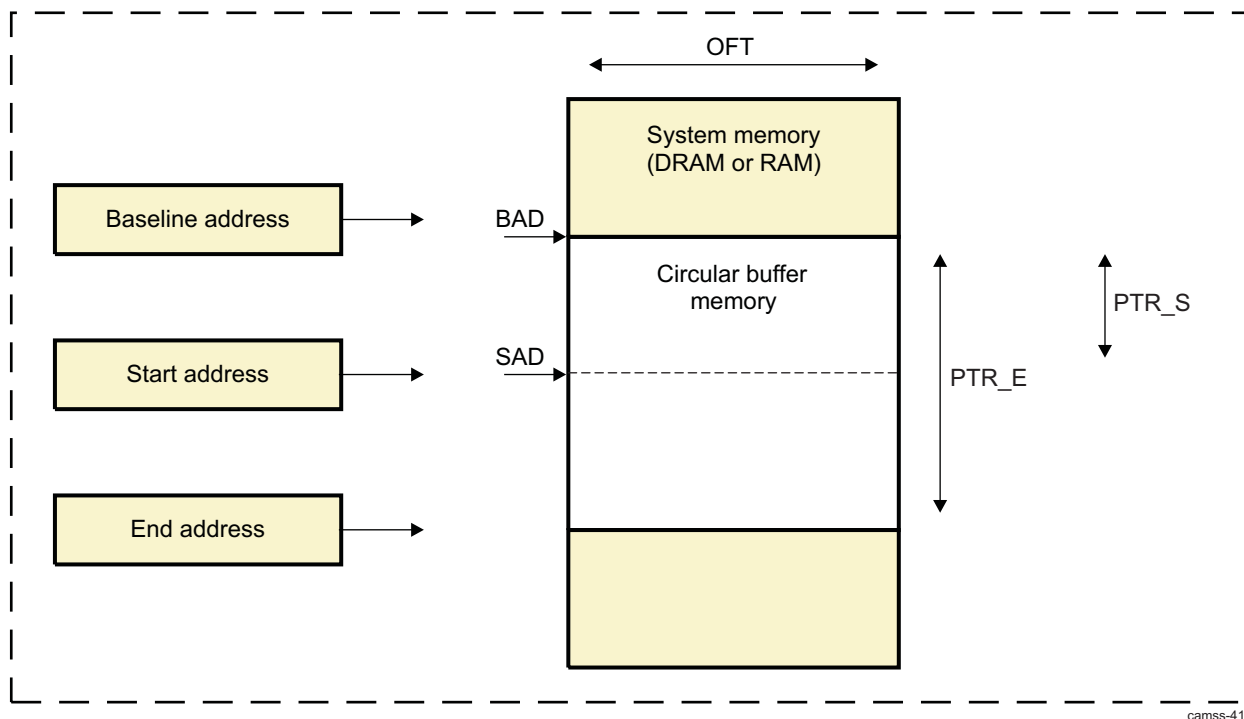

More generally, the following equations hold:

- $SAD = BAD + (PTR\_S \times OFT)$  and  $PTR\_S < PTR\_E$

Interrupts can be triggered every time a certain number of lines are written to the circular buffer. There are independent settings for each resizer and for each possible output of each resizer.

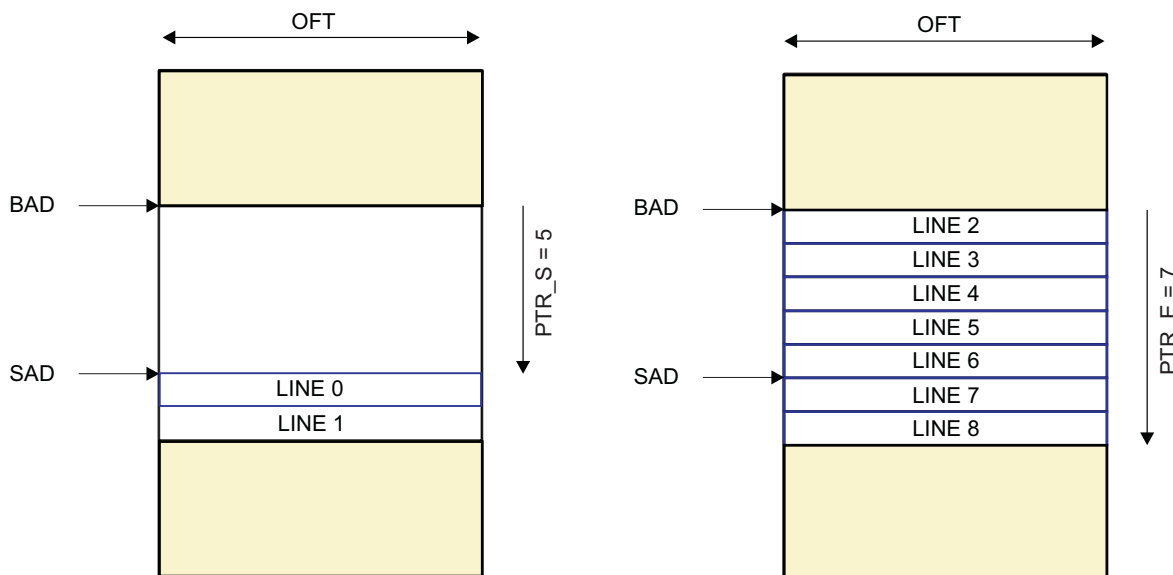

Figure 8-174. ISS ISP RSZ and Circular Buffer Settings

camss-410

Figure 8-175 shows how the data are stored in the circular buffer over time when vertical flip is disabled. In this example, PTR\_S = 5 and PTR\_E = 7. There can be up to PTR\_E = 7 lines in the circular buffer.

Figure 8-175. ISS ISP RSZ and Circular Buffer Settings – Example 1

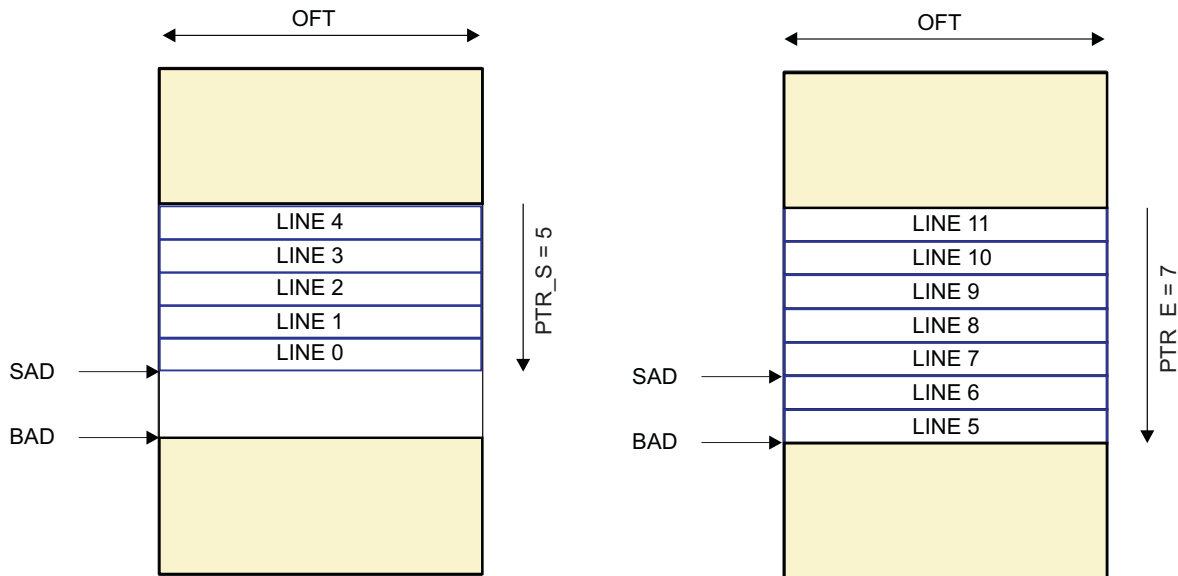

Vertical flip enabled:

1. Start from SAD.
2. Output PTR\_E – PTR\_S lines.
3. Wrap to BAD.
4. Output PTR\_E lines and continue wrapping to BAD.

camss-412

Figure 8-176 shows how the data are stored in the circular buffer over time when vertical flip is enabled. In this example, PTR\_S = 5 and PTR\_E = 7. There can be up to PTR\_E = 7 lines in the circular buffer.

**Figure 8-176. ISS ISP RSZ and Circular Buffer Settings – Example 2**

Vertical flip enabled:

1. Start from SAD.
2. Output PTR\_E – PTR\_S lines.
3. Wrap to BAD.
4. Output PTR\_E lines and continue wrapping to BAD.

camss-413

### 8.3.3.6 ISS ISP H3A Functional Description

#### 8.3.3.6.1 ISS ISP H3A Overview

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:
  - The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:
    - Peak mode in a paxel
      - Accumulation of the maximum focus value (FV) of each line in a paxel
    - Accumulation mode in a paxel
    - Accumulation of horizontal and vertical focus value in a paxel
    - Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
    - Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
    - Programmable width and height for the paxel/window
    - Programmable red, green, and blue position within a 2 x 2 matrix
    - Separate horizontal start for paxel and filtering

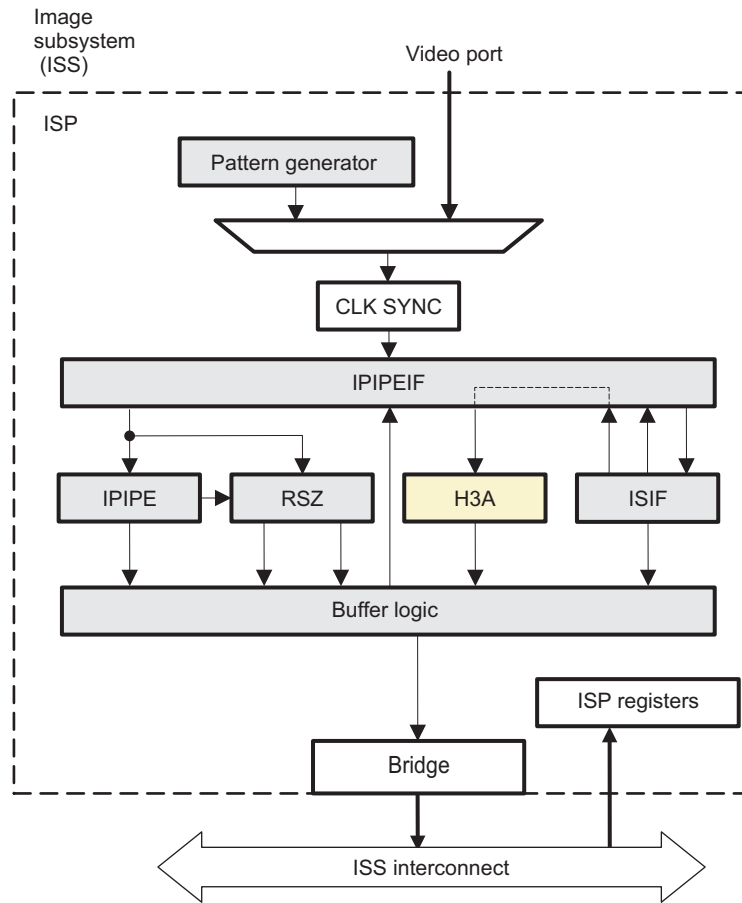

- Programmable vertical and horizontal line increments within a paxel
- Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame to focus on.
- Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.
- Auto exposure and auto white balance (AE/AWB) engine:
 

The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

  - Accumulate clipped pixels along with all nonsaturated pixels in each window per color
  - Accumulate the sum of squared pixels in each window per color
  - Minimum and maximum pixel values in each window per color
  - Supports for up to 36 horizontal windows with sum + { sum\_sq or min+max} output
  - Support for up to 56 horizontal windows with sum output
  - Support for up to 128 vertical windows
  - Programmable width and height for the windows. All windows in the frame are the same size.
  - Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
  - Programmable horizontal sampling points in a window
  - Programmable vertical sampling points in a window
- Maximum pixel throughput of 200 MPix/s
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 3008 pixels.

[Figure 8-177](#) shows the H3A module connections to other submodules of the ISP.

**Figure 8-177. ISS ISP H3A High-Level Diagram**

camss-003b

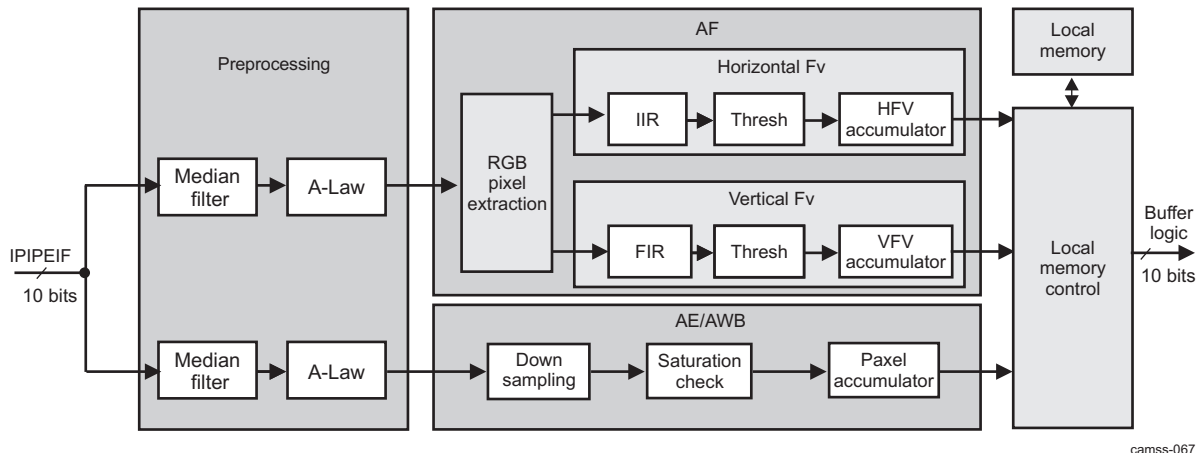

**8.3.3.6.2 ISS ISP H3A Top-Level Block Diagram**

The block diagram in [Figure 8-178](#) shows the process of the AF and AE/AWB data paths through the H3A module.

The data flow before H3A is:

1. Data comes from the VP (VP) or BL.
2. The data is processed by the ISIF.
3. The data is processed by the IPIPEIF.
4. The data is 10 bits from the IPIPEIF at H3A input.

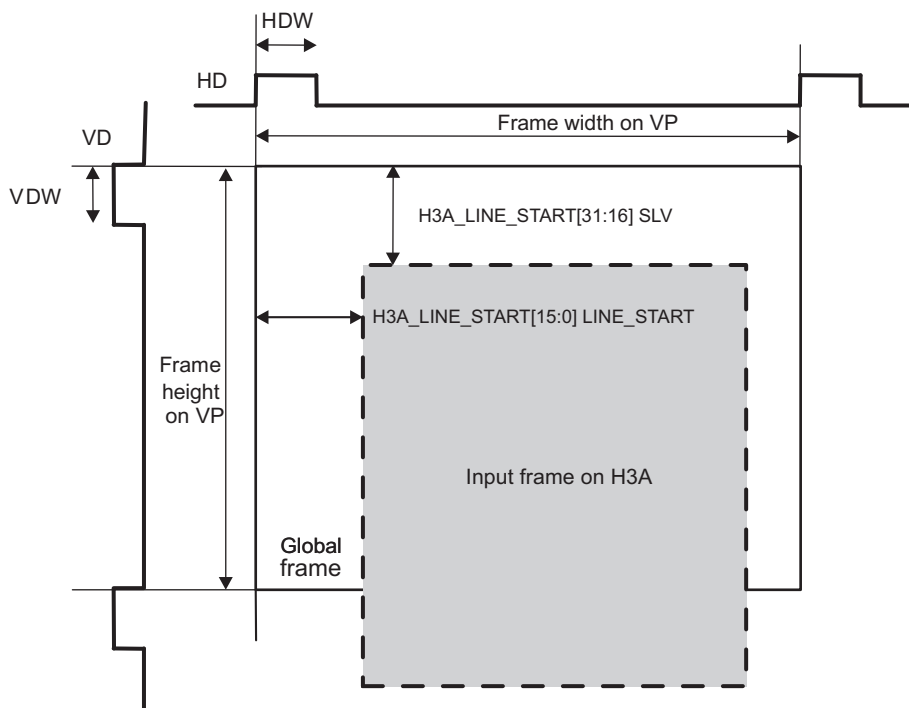

Figure 8-178. ISS ISP H3A Top-Level Block Diagram

### 8.3.3.6.3 ISS ISP H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the [H3A\\_LINE\\_START](#) register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 3008 pixels. After 3008 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 3008 clock cycles, then the active region ends immediately and the counter waits for the [H3A\\_LINE\\_START](#) register count to be reached again. For the vertical position the [H3A\\_LINE\\_START\[31:16\]](#) SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 8-179. ISS ISP H3A Frame Format Settings

---

**NOTE:** (Frame width on VP) - ([H3A\\_LINE\\_START\[15:0\]](#) LINE\_START) must be less than or equal to 3008, because the H3A memory lines are limited to 3008 pixels.

---

#### **8.3.3.6.4 ISS ISP H3A Optional Preprocessing**

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the [H3A\\_PCR\[1\]](#) AF\_ALAW\_EN bit) and the AE/AWB engine (the [H3A\\_PCR\[17\]](#) AEW\_ALAW\_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the [H3A\\_PCR\[2\]](#) AF\_MED\_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The horizontal median filter calculates the absolute difference between the current pixel ( $i$ ) and pixel ( $i - 2$ ), and between the current pixel ( $i$ ) and pixel ( $i + 2$ ). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel ( $i - 2$ ) and pixel ( $i + 2$ ) replaces pixel ( $i$ ). The threshold of the horizontal median filter can be set in the [H3A\\_PCR\[10:3\]](#) MED\_TH bit field.

#### **8.3.3.6.5 ISS ISP H3A Autofocus Engine**

The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending of whether A-Law is enabled or disabled) from the pixel value. The offset value is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and  $FV^2$  are produced. The FV and  $FV^2$  values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

##### **8.3.3.6.5.1 ISS ISP H3A Poxel Extraction**

From the poxel starting coordinate (the [H3A\\_AFPAXSTART\[27:16\]](#) PAXSH and [H3A\\_AFPAXSTART\[11:0\]](#) PAXSV bit fields) specifies the starting point of the poxel grid, with respect to first pixel of the input image frame.

The poxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if [H3A\\_PCR\[20\]](#) AF\_VF\_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the [H3A\\_PCR \[13:11\]](#) RGBPOS bit field to extract the correct colors from the input stream. [Figure 8-181](#) shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each  $2 \times 2$  grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

**Figure 8-180. ISS ISP H3A Red, Green, and Blue Pixel Extraction Examples**

camss-068

Each paxel is  $H3A\_AFPAX1[23:16]$  PAXW  $\times$   $H3A\_AFPAX1[7:0]$  PAXH (width  $\times$  height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every  $H3A\_AFPAX2[16:13]$  AFINCV lines. Vertical FV can skip columns, operating on one every  $H3A\_AFPAX2[20:17]$  AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH)  $\geq$  32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column  $H3A\_AFIIRSH[11:0]$  IIRSH.

Figure 8-181. ISS ISP H3A Horizontal/Vertical FV Poxel Configuration

camss-071

**NOTE:**  $(H3A\_AFPAXSTART[27:16] PAXSH) + (H3A\_AFPAX2[5:0] PAXHC) \times (H3A\_AFPAX1[23:16] PAXW) \leq [(Frame\ width\ on\ VP) - (H3A\_LINE\_START[15:0] LINE\_START)] \leq 3008$

Table 8-328 lists the register fields that configure the size and number of paxels.

Table 8-328. ISS ISP H3A Poxel Register Field Descriptions

Register Field	Bit Width	Description
<a href="#">H3A_AFPAX1[23:16]</a> PAXW	8	Poxel width (in pixels)
<a href="#">H3A_AFPAX1[7:0]</a> PAXH	8	Poxel height (in lines)
<a href="#">H3A_AFPAX2[5:0]</a> PAXHC	6	Poxel count for horizontal direction
<a href="#">H3A_AFPAX2[12:6]</a> PAXVC	7	Poxel count for vertical direction
<a href="#">H3A_AFPAX2[16:13]</a> AFINCV	4	Line increments in a poxel
<a href="#">H3A_AFPAX2[20:17]</a> AFINCH	4	Column increments in a poxel
<a href="#">H3A_AFPAXSTART[27:16]</a> PAXSH	12	Poxel start position H
<a href="#">H3A_AFPAXSTART[11:0]</a> PAXSV	12	Poxel start position V
<a href="#">H3A_AFIIRSH[11:0]</a> IIRSH	12	IIR filter start position

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the [H3A\\_ADVANCED\[31:15\]](#) ID bit field, then [H3A\\_ADVANCED\[0\]](#) AF\_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF poxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV\_1 and HFV\_2.

### 8.3.3.6.5.2 ISS ISP H3A Horizontal FV Calculator

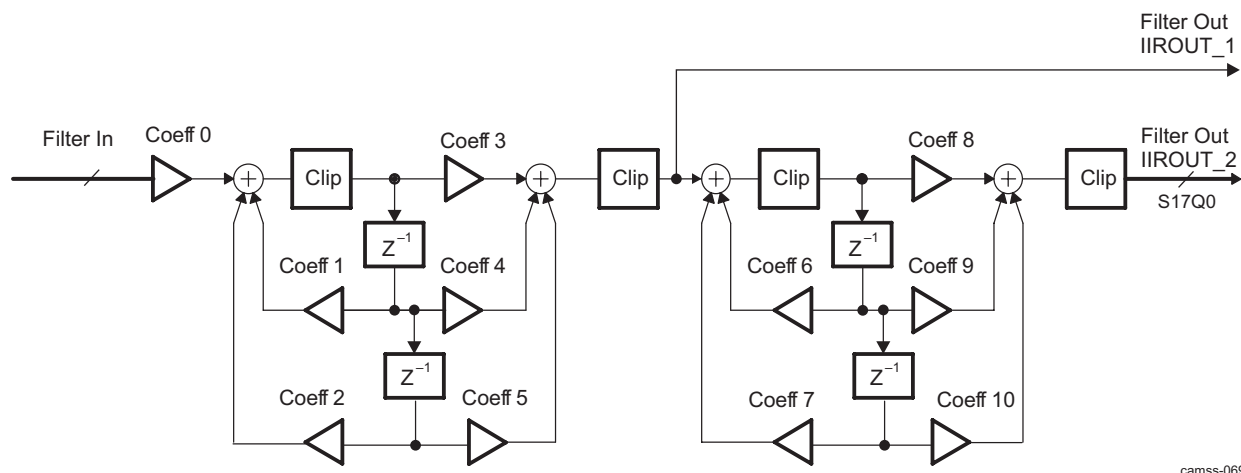

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range [-128:127] or [-512:511].

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide with 6 bits of decimal, S12Q6 ([H3A\\_AFCOE0F10](#) to [H3A\\_AFCOE0F010](#) for SET0, and [H3A\\_AFCOE1F10](#) to [H3A\\_AFCOE1F010](#) for SET1). The filter-shift registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the [H3A\\_AFIIRSH](#) [11:0] IIRSH bit field). The absolute values of the output (16-bits-wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is  $m$  bits (signed) and the required output value is  $n$  bits, clipping transforms the input to between  $-2^1$  and  $2^1$ . Values lower than  $-2^1$  are set to  $-2^1$ , and values higher than  $2^1$  are set to  $2^1$ .

Figure 8-182 shows the IIR filter model.

**Figure 8-182. ISS ISP H3A IIR Filter Model**

camss-069

### 8.3.3.6.5.3 ISS ISP H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each pixel. The size and number of pixels is configurable by registers.

Table 8-328 lists the register fields that configure the size and number of pixels:

- In peak mode ([H3A\\_PCR](#)[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode ([H3A\\_PCR](#)[14] FVMODE = 0x0), all HFV<sub>n</sub> are accumulated in a pixel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV<sub>n</sub> (HFV<sub>n\_peak</sub> for peak mode or HFV<sub>n\_sum</sub> for sum mode)
- HFV<sub>count\_n</sub>
- HFV<sub>sq\_n</sub> (HFV<sub>sq\_n\_peak</sub> for peak mode or HFV<sub>sq\_n\_sum</sub> for sum mode)

$n = 1$  or  $2$  for IIR1 and IIR2, respectively.

For each pixel, these six values are available for each R, G, and B component.

```
for (k=0; k<PAXH) // Loop on pixel rows
{
    rowpeak_n = 0;

    for (l=0; l<PAXW; l++) // Loop on values within a row
    {
        aIIRout_n = ABS(IIRout_n);
        if (aIIRout_n >= threshold_n)
        {
            hfval = aIIRout_n - threshold_n;
            HFV_count_n++;
        }
    }
}
```

```

else hfval = 0;
if (hfval > rowpeak_n)
{
rowpeak_n = HFV_n;
}
HFV_n_sum += hfval;
HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
} // Finished looping on values in a row
HFV_n_peak += rowpeak_n;
HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;
}

```

- threshold\_n is [H3A\\_HVF\\_THR\[15:0\]](#) HTHR1 and [H3A\\_HVF\\_THR\[31:16\]](#) HTHR2, respectively.
- IIRout\_n is the IIRout\_1 and IIRout\_2 outputs, respectively.
- HFV\_count\_n and HFV\_sq\_n are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.
- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
  - HFV\_n = HFV\_n\_sum
  - HFV\_sq\_n = HFV\_sq\_n\_sum
- In peak mode:
  - HFV\_n = HFV\_n\_peak
  - HFV\_sq\_n = HFV\_sq\_n\_peak

#### 8.3.3.6.5.4 ISS ISP H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1\_x, where x = 0..4, in the [H3A\\_VFV\\_CFG1](#) and [H3A\\_VFV\\_CFG2](#) registers for FIR 1, and VCOEF2\_x, where x = 0..4, in [H3A\\_VFV\\_CFG3](#) and [H3A\\_VFV\\_CFG4](#) registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and taken absolute value to produce a 16-bit unsigned value. This is then sent to threshold [H3A\\_VFV\\_CFG2\[31:16\]](#) VTHR1 for FIR 1, and [H3A\\_VFV\\_CFG4\[31:16\]](#) VTHR2 for FIR 2, and square logic to produce VFV\_n and VFV\_sq\_n.

#### 8.3.3.6.5.5 ISS ISP H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each paxel. The size and number of paxels is configurable by registers.

[Table 8-328](#) lists the register fields that configure the size and number of paxels.

The following equations detail the calculation for:

- VFV\_n
- VFV\_count\_n
- VFV\_sq\_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```

FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;

if (aFIRout_n >= threshold_n)
{
VFV_n = aFIRout_n - threshold_n
VFV_count_n++;
}

```

```
else VFV_n = 0;
```

```
VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;
```

- threshold\_n is [H3A\\_VFV\\_CFG2\[31:16\]](#) VTHR1 and [H3A\\_VFV\\_CFG4\[31:16\]](#) VTHR2, respectively.
- FIRout\_n is the FIRout\_1 and FIRout\_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

### 8.3.3.6.6 ISS ISP H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into  $2 \times 2$  blocks. For each subsampled  $2 \times 2$  block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a  $2 \times 2$  block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the [H3A\\_AEWCFG\[9:8\]](#) AEFMT bit field:

- Sum of square mode: [H3A\\_AEWCFG\[9:8\]](#) AEFMT = 0x0
- Min/max mode: [H3A\\_AEWCFG\[9:8\]](#) AEFMT = 0x1
- Sum-only mode: [H3A\\_AEWCFG\[9:8\]](#) AEFMT = 0x2

#### 8.3.3.6.6.1 ISS ISP H3A Subampler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in [Figure 8-179](#). Each window is further sampled down to a set of  $2 \times 2$  blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in [Figure 8-179](#).

**Figure 8-183. ISS ISP H3A AE/AWB Window Configurations**

[Table 8-329](#) lists the register fields that configure the window and block sizes, counts, and starting positions.

**Table 8-329. ISS ISP H3A AE/AWB Window Register Field Descriptions**

Register Field	Bit Width	Description
<a href="#">H3A_AEWWIN1[20:13]</a> WINW	7	Window width (in pixels)
<a href="#">H3A_AEWWIN1[31:24]</a> WINH	7	Window height (in lines)
<a href="#">H3A_AEWWIN1[5:0]</a> WINHC	6	Window count for horizontal direction

**Table 8-329. ISS ISP H3A AE/AWB Window Register Field Descriptions (continued)**

Register Field	Bit Width	Description
H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
H3A_AEWINSTART[11:0] WINSH	12	Window start position H
H3A_AEWINSTART[27:16] WINSV	12	Window start position V
H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples

**8.3.3.6.2 ISS ISP H3A Additional Black Row of AE/AWB Windows**

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the H3A\_AEWINBLK[27:16] WINSV bit field, and the height is specified in the H3A\_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 8-184 shows a black row of windows before rows of windows.

**Figure 8-184. ISS ISP H3A Black Row of Windows Before Regular Rows of Windows**

**Table 8-330. ISS ISP H3A AE/AWB Window with Additional Black Row Register Field Descriptions**

Register Field	Bit Width	Description
H3A_AEWWIN1[20:13] WINW	7	Window width (in pixels)
H3A_AEWWIN1[31:24] WINH	7	Window height (in lines)
H3A_AEWWIN1[5:0] WINHC	6	Window count for horizontal direction
H3A_AEWWIN1[12:6] WINVC	7	Window count for vertical direction
H3A_AEWINSTART[11:0] WINSH	12	Window start position H
H3A_AEWINSTART[27:16] WINSV	12	Window start position V
H3A_AEWSUBWIN[3:0] AEWINCH	4	Horizontal distance between subsamples
H3A_AEWSUBWIN[11:8] AEWINCV	4	Vertical distance between subsamples
H3A_AEWINBLK[27:16] WINSV	12	Window start position H for single black line
H3A_AEWINBLK[6:0] WINH	7	Window height (in lines) for single black line

### 8.3.3.6.6.3 ISS ISP H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the [H3A\\_PCR](#) [31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the 2 × 2 block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

### 8.3.3.6.6.4 ISS ISP H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every 2 × 2 pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a 2 × 2 pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the 2 × 2 pixel grid is associated with a color (R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See [Section 8.3.3.6.4](#) for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the [H3A\\_AEWCFG](#)[3:0] SUMSHFT bit field.

### 8.3.3.6.7 ISS ISP H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent out to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the [H3A\\_AFBUFST](#)[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the [H3A\\_AEWBUFST](#)[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of pixels or windows. This requires that each horizontal row of pixels or windows starts and ends on a 32-byte boundary. If a horizontal row of pixels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the 8<sup>th</sup> consecutive window.

[Table 8-331](#) lists the packet formats for AF with vertical AF disabled.

**Table 8-331. ISS ISP H3A AF Packet Format With Vertical AF Disabled**

### 8.3.3.6.8 ISS ISP H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the interrupt service routine does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last paxel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and interrupt service routine execution.

The [H3A\\_PCR\[15\]](#) BUSYAF and/or [H3A\\_PCR\[18\]](#) BUSYAEAWB status bits are set when the start of frame occurs (if the [H3A\\_PCR\[0\]](#) AF\_EN and/or [H3A\\_PCR\[16\]](#) AEW\_EN bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The [H3A\\_PCR\[15\]](#) BUSYAF and/or [H3A\\_PCR\[18\]](#) BUSYAEAWB status bits may be polled to determine the end of frame status.

### 8.3.3.7 ISS ISP ISIF Functional Description

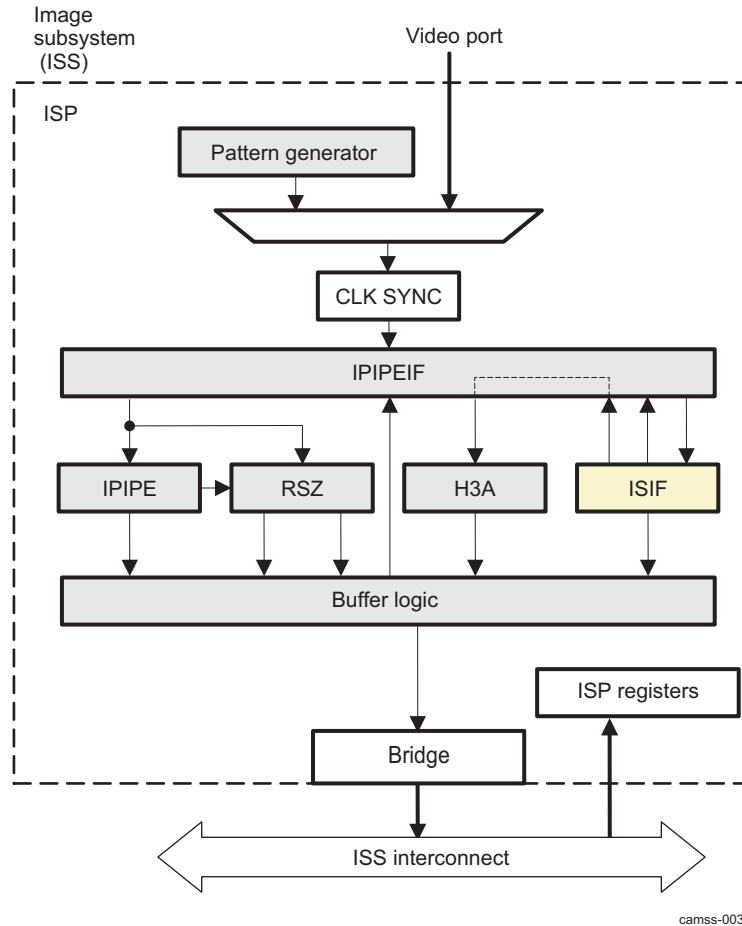

#### 8.3.3.7.1 ISS ISP ISIF Overview

The image sensor interface (ISIF) module receives RAW or YUV4:2:2 data from the IPIPEIF module. The module outputs data back to the IPIPEIF module and can also output data to memory through the BL module. The ISIF module can process the incoming data and supports the following functions:

- Maximum supported image size is 32,768 × 32,768
- Supports up to 16-bit analog front end
- Sensor data linearization
- Supports Bayer and Foveon® input data format (RGB and CMYG color support)
- Supports VGA read out mode
- Supports various image data format
- Color space conversion
- Digital clamp with horizontal/vertical offset drift compensation
- Vertical line defect correction
- Programmable 2D-matrix LSC
- Gain and offset control
- Programmable horizontal/vertical culling pattern
- Maximum pixel rate clock of 200 MPix/s on the VP interface.
- 10-to-8-bit A-Law compression table inside
- 12-bit pack supported when written to memory

[Figure 8-186](#) show the ISIF module connections to other submodules of the ISP.

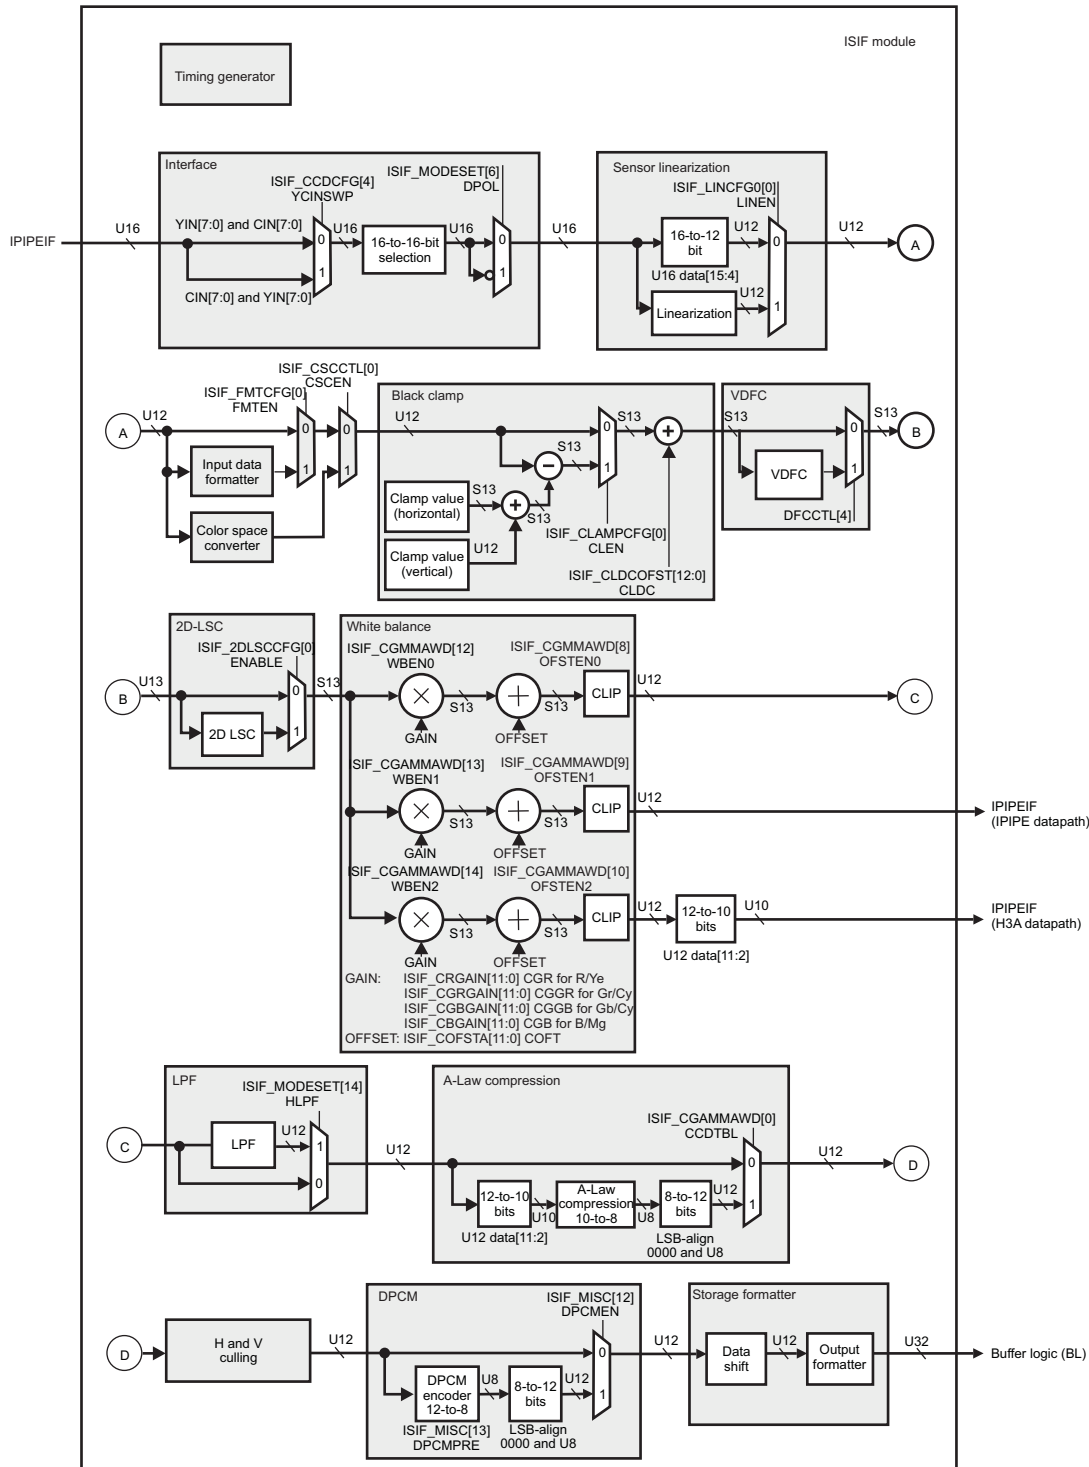

**Figure 8-186. ISS ISP ISIF High-Level Diagram**

**8.3.3.7.2 ISS ISP ISIF Top-Level Block Diagram**

Figure 8-187 shows the different blocks of the ISIF module.

Figure 8-187. ISS ISP ISIF Top-Level Block Diagram

camss-074

The following sections describe the blocks in the ISIF module.

8.3.3.7.3 ISS ISP ISIF Input Interface

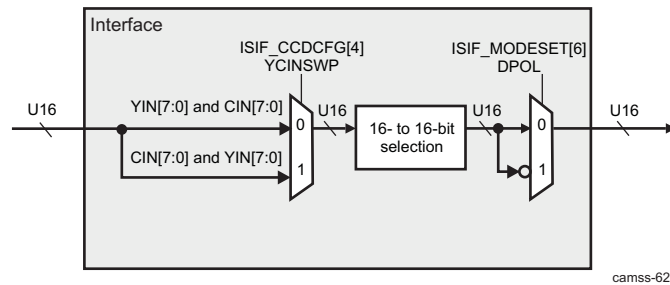

The input interface is a video interface. It comprises the horizontal(HD)I and vertical(VD) synchronization signal, pixel clock (PCLK), and data(DATA). Table 8-336 gives more information about these different signals. The ISIF uses the HD and VD signals provided by the sensor through the VP and IPIPEIF. The pixel clock clocks data into the ISIF at a maximum rate of MHz.

Table 8-336. ISS ISP ISIF Input Interface Signals

Name	I/O	Function
VD	I	Vertical sync signal
HD	I	Horizontal sync signal
PCLK	I	Pixel clock. This signal is the pixel clock used to load image data into the ISIF. The clock controller can configure to trigger on the rising or falling edge of the PCLK signal.
DATA	I	Data. The data interface is a 16-bit interface. When the ISIF is configured to write data to SDRAM, the write enable signal allows an external device to control which data is to be written to SDRAM. The data input can be configured from the ISIF_MODESET.INPMOD register where it can be set to RAW, YCbCr (16 bits and 8 bits). The polarity of the data can be changed from the ISIF_MODESET.DPOL as shown in Figure 8-188.

8.3.3.7.4 ISS ISP ISIF Interface

Figure 8-188. ISS ISP ISIF Interface Block Diagram

The ISIF supports 8- to 16-bit-wide RAW data signals and 8-/16-bit YCbCr signals, as described in Table 8-337. The interface can be set in the three different modes from the ISIF\_MODESET[13:12] INPMOD bit field. The ISIF\_CCDCFG[11] Y8POS bit selects the y signal positioning whenever YUV4:2:2 is input. Moreover, if CCIR656 input is used the width of selected bit can be set through the ISIF\_CCDCFG[5] BT656 bit.

Table 8-337. ISS ISP ISIF Data Input Formats

ISIF Input Port Name	RAW Data	16-bit YCbCr	8-bit YCbCr
Y17	C_DATA15	Y7	
Y16	C_DATA14	Y6	
Y15	C_DATA13	Y5	
Y14	C_DATA12	Y4	
Y13	C_DATA11	Y3	
Y12	C_DATA10	Y2	
Y11	C_DATA9	Y1	

**Table 8-337. ISS ISP ISIF Data Input Formats (continued)**

ISIF Input Port Name	RAW Data	16-bit YCbCr	8-bit YCbCr
Y10	C_DATA8	Y0	
Cl7	C_DATA7	Cb7,Cr7	Y7,Cb7,Cr7
Cl6	C_DATA6	Cb6,Cr6	Y6,Cb6,Cr6
Cl5	C_DATA5	Cb5,Cr5	Y5,Cb5,Cr5
Cl4	C_DATA4	Cb4,Cr4	Y4,Cb4,Cr4
Cl3	C_DATA3	Cb3,Cr3	Y3,Cb3,Cr3
Cl2	C_DATA2	Cb2,Cr2	Y2,Cb2,Cr2
Cl1	C_DATA1	Cb1,Cr1	Y1,Cb1,Cr1
Cl0	C_DATA0	Cb0,Cr0	Y0,Cb0,Cr0

Y and C input signals can be swapped through the [ISIF\\_CCDCFG\[4\]](#) YCINSWP bit.

In case of RAW data at ISIF input, a 16- to-16-bit selection can be done: when the number of RAW data lines is less than 16, data can be connected to the upper or lower lines of C\_DATA[15:0]. Lines not connected must be tied low. As shown in [Table 8-338](#), the [ISIF\\_CGAMMAWD\[4:1\]](#) GWDI bit field must be configured correctly so that the MSB of the input is connected to the MSB of the 16-bit data bus in ISIF.

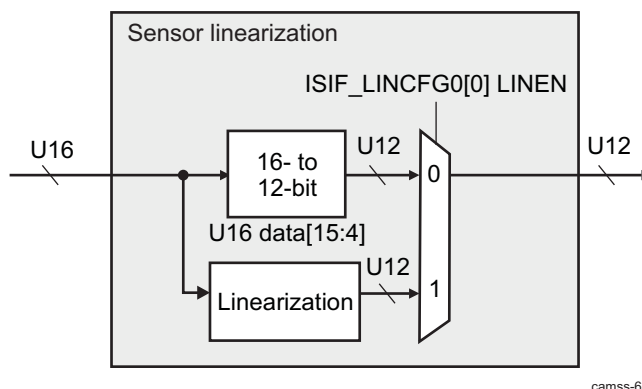

**Table 8-338. ISS ISP ISIF Raw Data Connection: Selects MSB Position of Input Data**

ISIF_CGAMMAWD[4:1] GWDI	16-to-16-bit Selection
0	C_DATA [15:0] = C_DATA[15:0]
1	C_DATA [15:0] = C_DATA[14:0] & 0
2	C_DATA [15:0] = C_DATA[13:0] & 00
3	C_DATA [15:0] = C_DATA[12:0] & 000
4	C_DATA [15:0] = C_DATA[11:0] & 0000
5	C_DATA [15:0] = C_DATA[10:0] & 00000
6	C_DATA [15:0] = C_DATA[9:0] & 000000
7	C_DATA [15:0] = C_DATA[8:0] & 0000000
8	C_DATA [15:0] = C_DATA[7:0] & 00000000

The polarity of the input image data can be switched through the [ISIF\\_MODESET\[6\]](#) DPOL bit.

### 8.3.3.7.5 ISS ISP ISIF Sensor Linearization

**NOTE:** For the memory access locations of the sensor linearization table, see [Section 8.3.3.9](#).

**Figure 8-189. ISS ISP ISIF Sensor Linearization Block Diagram**

The sensor linearization module can correct for the non-linear response of image sensors. A LUT is programmed with an offset value to add to the original pixel value based on the original pixel value.

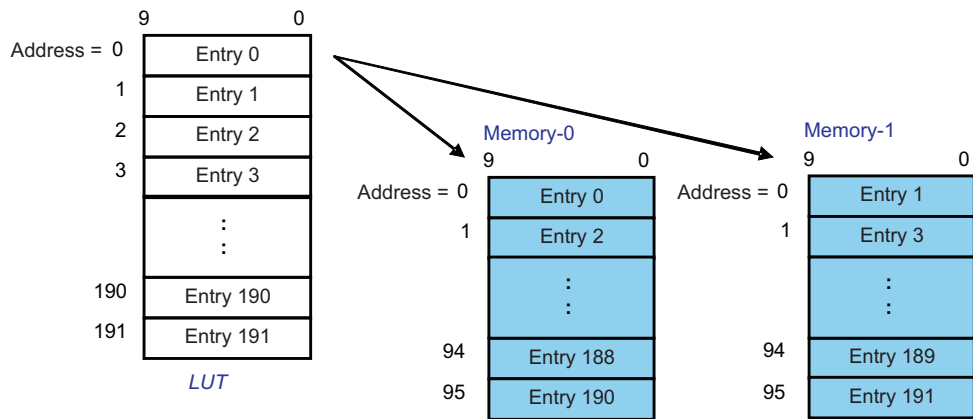

The LUT is a sampling of the linearization correction curve based on calibration of the image sensor. Intermediate values between sampling points are computed using linear interpolation. The entire correction curve is divided into seven regions, as shown in Table 8-339. The regions for the darkest part and the brightest part of the response curve have dense sampling. The linearization mode can be a uniform or a non-uniform sampling and can be set through the ISIF\_LINCFG0[1] LINMD bit.

**Table 8-339. ISS ISP ISIF Linearization LUT**

Region	Number of Sample Points	LUT Address
table_in[15:11] == 00000	32	table_in[10:6]
table_in[15:11] == 00001	4	table_in[10:9] + 32
table_in[15:12] == 0001	4	table_in[11:10] + 36
table_in[15:13] == 001	4	table_in[12:11] + 40
table_in[15:14] == 01	4	table_in[13:12] + 44
table_in[15:14] == 10	16	table_in[13:10] + 48
table_in[15:14] == 01	128	table_in[13:7] + 64

The LUT has 192 entries and is split into two 96 × 10-bit memories, as shown in Figure 8-190. The table is mapped in the memory map. The LUT entries are interleaved between memory 0 and memory 1.

**Figure 8-190. ISS ISP ISIF Linearization LUT Memories**

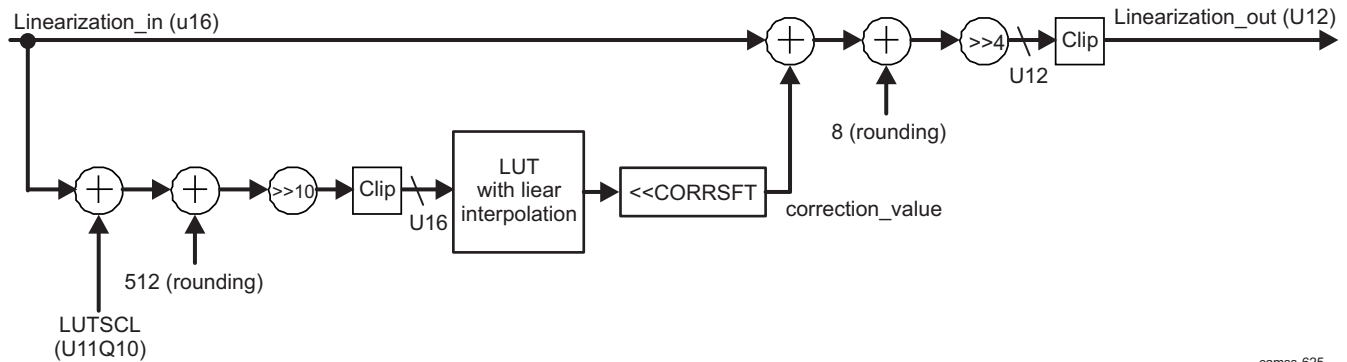

camss-613

**Table 8-340. ISS ISP ISIF LUT Memory Region**

Memory Region	Address Range	Description
Memory 0	0xC000 – 0xC17F	ISIF linearity compensation LUT 0
Memory 1	0xC400 – C57F	ISIF linearity compensation LUT 1

A scale factor is applied to the input before lookup through the `ISIF_LINCFG1[10:0]` LUTSCL bit field. The LUT entries are signed 10-bit data (u16). After linear interpolation, the correction value is left-shifted by a programmable amount (the `ISIF_LINCFG0[6:4]` CORRSFT bit field), and then added to the input. This is then converted to unsigned 12-bit by right shift, followed by clipping.

**Figure 8-191. ISS ISP ISIF Linearization Block Diagram**

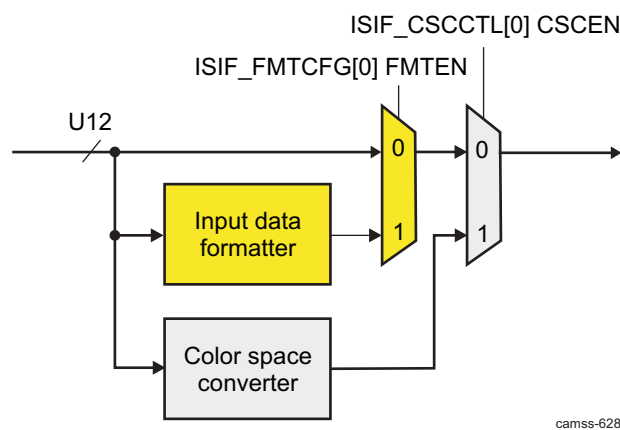

camss-625

To enable the linearization module, set the `ISIF_LINCFG0[0]` LINEN bit to 1.

If the linearization module is disabled (`ISIF_LINCFG0[0]` LINEN = 0x0), a 16- to-12-bit transformation is done, and the upper 12-bits of U16 input are sent to the next block.

### 8.3.3.7.6 ISS ISP ISIF Input Data Formatter

**Figure 8-192. ISS ISP ISIF Input Data Formatter Block Diagram**

camss-628

There are two functional blocks: input data formatter and color space converter, which use two  $5376 \times 12$ -bit memories (corresponds to one line of maximum 5376 pixels with each pixel equal to 12 bits). Only one of the function blocks can be enabled.

The input data formatter block allows the ISIF to handle a wide variety of current and future readout schemes other than Bayer format. Two line memories and a programmable address generator are used to translate those patterns into a standard Bayer pattern (or any other pattern). This allows the back-end processing (noise filters, interpolation, histogram, 3A statistics) to remain unchanged.

The input data formatter block also supports divided input lines. In case an input line is divided into multiple lines and fed to the ISIF, the formatter gathers the divided lines and organizes a single line. Up to four divided lines can be supported.

The input data formatter is enabled through the `ISIF_FMTCFG[0]` FMTEN bit.

The input data formatter can split an input line into 1, 2, 3, or 4 output lines, or can combine the divided 1, 2, 3, or 4 input lines into a single line.

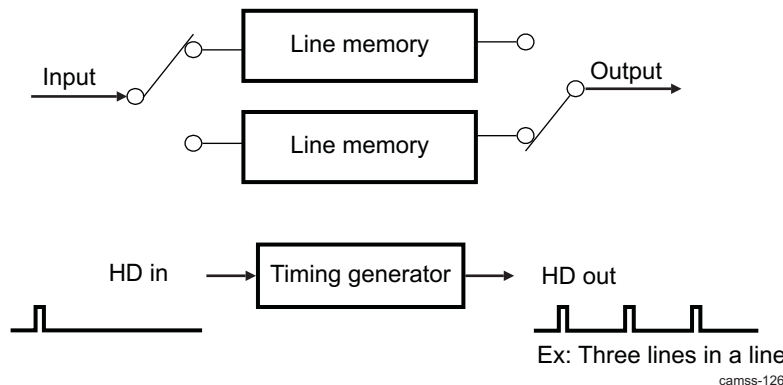

- Set the `ISIF_FMTCFG[1]` FMTCBL bit to 0 for split mode.

- Set the `ISIF_FMTCFG[1]` FMTCBL bit to 1 for combine mode.
- Select the number of lines in the `ISIF_FMTCFG[5:4]` LNUM bit field.

The Input data formatter can work in normal or line alternative mode. The choice is done through the `ISIF_FMTCFG[2]` LNALT bit.

Figure 8-193 shows an example of generating three output lines from an input line with a new, internally generated HD signal.

**Figure 8-193. ISS ISP ISIF Splits an Input Line Into Three Output Lines**

This HD signal then gates the downstream processing rather than the original sensor HD signal. Descriptions of how to configure the formatter are provided in the following sections.

Because the size of the line memories is 5376 × 12 bits, the following restrictions apply for the data formatter:

- Split mode:
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into 1 output line is 5376.
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into 2 output lines is 2688.
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into 3 output lines is 1792.
  - The maximum number of pixels that can be supported in an output line if the input line is transformed into 4 output lines is 1344.
- Combine mode:
  - The maximum number of pixels that can be supported in an input line if 1 input line is transformed into an output line is 5376.
  - The maximum number of pixels that can be supported in an input line if 2 input lines are transformed into an output line is 2668.
  - The maximum number of pixels that can be supported in an input line if 3 input lines are transformed into an output line is 1792.
  - The maximum number of pixels that can be supported in an input line if 4 input lines are transformed into an output line is 1344.

#### 8.3.3.7.6.1 ISS ISP ISIF Formatter Area Settings

As shown in Figure 8-194, the following registers are used to set the formatter area:

- `ISIF_FMTSPH`
- `ISIF_FMTLNH`
- `ISIF_FMTLSV`
- `ISIF_FMTLNV`

Table 8-341 describes these registers. The input line is input to the formatter, and the output line is output from the formatter.

**Figure 8-194. ISS ISP ISIF Input Data Formatter Area Settings**

camss-112

**Table 8-341. ISS ISP ISIF Input Data Formatter Area Setting Registers**

Register	Description
<a href="#">ISIF_FMTSPH</a>	The first valid pixel of an input line
<a href="#">ISIF_FMTLNH</a>	Valid length of a input line = FMTLNH + 1
<a href="#">ISIF_FMTLSV</a>	The first valid input line
<a href="#">ISIF_FMTLNV</a>	The number of the valid input lines = FMTLNV + 1

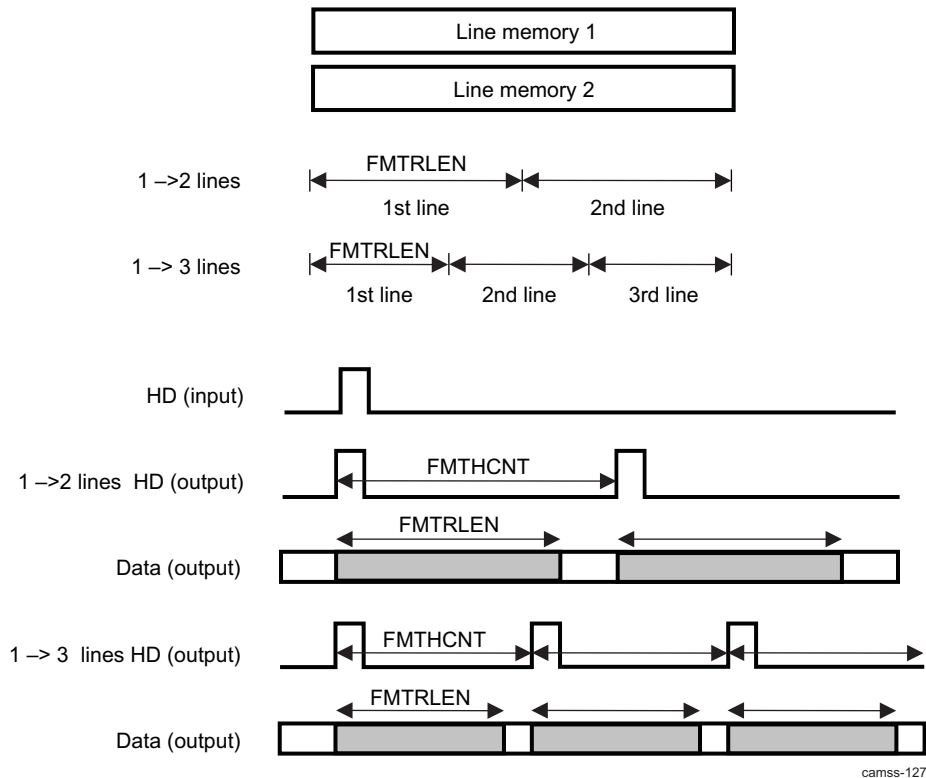

**Table 8-342. ISS ISP ISIF Output Data Formatter Area Setting Registers**

Register	Description
<a href="#">ISIF_FMTRLEN</a>	The length of an output line
<a href="#">ISIF_FMTHCNT</a>	HD interval for output lines
<a href="#">ISIF_SPH</a>	The first pixel in an output line to be stored to SDRAM
<a href="#">ISIF_LNH</a>	Number of pixels in an output line to be stored to SDRAM = LNH + 1
<a href="#">ISIF_LNV</a>	The number of the output lines to be stored to SDRAM = LNV + 1

The number of pixels in an output line must be set to the [ISIF\\_FMTRLLEN](#) register, and the HD output interval must be set to the [ISIF\\_FMTHCNT](#) register. It is not necessary to set the [ISIF\\_FMTHCNT](#) register if multiple input lines are combined into a single line.

[Figure 8-195](#) shows an example of splitting an input line into two or three output lines.

**Figure 8-195. ISS ISP ISIF Data Formatter Output Control Example**

### 8.3.3.7.6.2 ISS ISP ISIF Formatter Programming

The data formatter derives its flexibility by supporting up to 16 different addresses and a program that can contain up to 32 entries.

#### Address pointer

There are 16 address pointer registers ([ISIF\\_FMTAPTR0](#) to [ISIF\\_FMTAPTR15](#)), which contain:

- The [ISIF\\_FMTAPTRx\[14:13\]](#) LINE bit field: 2-bit line number to specify the output line to which it belongs: 0, 1, 2, or 3. It is valid only for the line splitting.
- The [ISIF\\_FMTAPTRx\[12:0\]](#) INIT bit field: 13-bit initial address for pointer x (where x = 0 to 15)

Each of the address values is auto-incremented or auto-decremented by a programmable value (the [ISIF\\_FMTCFG\[11:8\]](#) FMTAINC bit field).

#### Program

There are 32 program entry registers, which contain:

- In the [ISIF\\_FMTPGMVFO](#) and [ISIF\\_FMTPGMVF1](#) registers: The PGMxxEN fields (where xx = 00 to 31) set the program entry valid flag.
- In the [ISIF\\_FMTPGMAPS0](#) to [ISIF\\_FMTPGMAPS7](#) registers: The PGMxxAPTR fields specify the program xx address pointer (where xx = 00 to 31).
- In the [ISIF\\_FMTPGMAPU0](#) and [ISIF\\_FMTPGMAPU1](#) registers: The PGMxxUPDT fields (where xx = 00 to 31) set the program xx address update (increment or decrement).

Because each of the program entries has a valid flag, the formatter can also support images larger than the memory limit (length: 4480) by not choosing some of the entries.

The total program memory of 32 entries is divided into two or four SETs:

- Program memory of 16 entries each for odd and even lines to split the line:
  - SET0 for even input line: Program entry 015
  - SET1 for odd input line: Program entry 1631
- Program memory of eight entries for up to four input lines to combine the lines:
  - SET0 for first input line: Program entry 07
  - SET1 for second input line: Program entry 815
  - SET2 for third input line: Program entry 1623
  - SET3 for fourth input line: Program entry 2431

The number of program entries per SET must be specified by the **ISIF\_FMTPLEN** register as follows:

- Number of program entries for SET0: **ISIF\_FMTPLEN**[3:0] FMTPLEN0
- Number of program entries for SET1: **ISIF\_FMTPLEN**[7:4] FMTPLEN1
- Number of program entries for SET2: **ISIF\_FMTPLEN**[10:8] FMTPLEN2
- Number of program entries for SET3: **ISIF\_FMTPLEN**[14:12] FMTPLEN3

The program entry must be set from the lower registers within a SET. For instance, start from program entry 16 for odd input lines.

The following examples show the programmability of the data formatter:

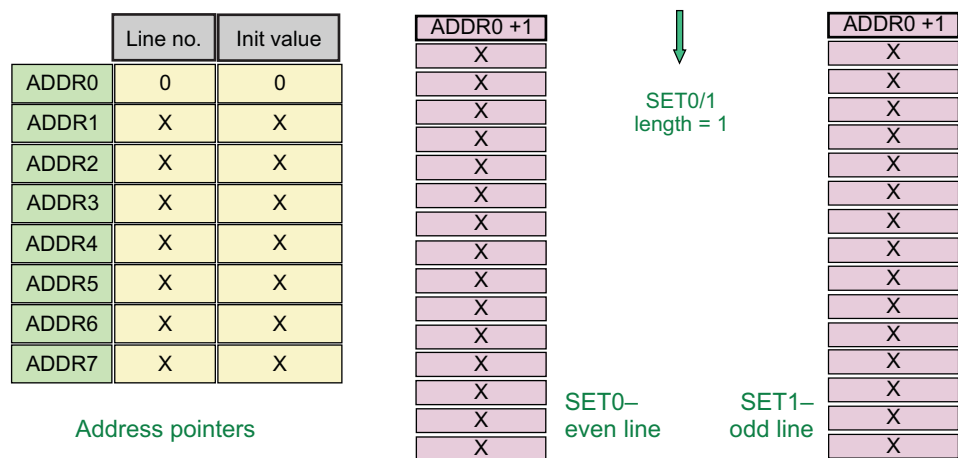

- Register settings:
  - **ISIF\_FMTCFG**[0] FMTEN = 0x1
  - **ISIF\_FMTCFG**[1] FMTCBL = 0x0
  - **ISIF\_FMTCFG**[11:8] FMTAINC = 0x0 (add or subtract 1)
- 1 input line -> 1 output line

---

**NOTE:** ADDR0 is set to an example value. Addresses with no value in the following example are marked with X.

---

**Figure 8-196. ISS ISP ISIF Conventional Read-Out Pattern**

camss-128

The following examples show the programmability of the data formatter with a 2-tap analog front end (AFE):

- Register settings:
  - **ISIF\_FMTCFG**[0] FMTEN = 0x1

- ISIF\_FMTCFG[1] FMTCBL = 0x0
- ISIF\_FMTCFG[11:8] FMTAINC = 0x0 (add or subtract 1)
- ISIF\_FMTCFG[5:4] LNUM = 0x0
- One input line (4096) -> one output line with left and right read-out
- Input -> First pixel, last pixel, first pixel + 1, last pixel - 1, and so on
- Input -> 0, 4095, 1, 4094, 2, 4093, 3, 4092, ..., 2047 and 2048
- Output -> 0, 1, 2, 3, ..., 4094 and 4095

Figure 8-197. ISS ISP ISIF Conventional Read-Out Pattern With 2-tap AFE

8.3.3.7.6.3 ISS ISP ISIF Combine the Divided Input Lines

The formatter can gather the divided input lines and organize a single line. Figure 8-198 shows an example generating a single output line from three input lines and masking two out of three HD input pulses.

Figure 8-198. ISS ISP ISIF Combine Three Input Lines Into Single Line

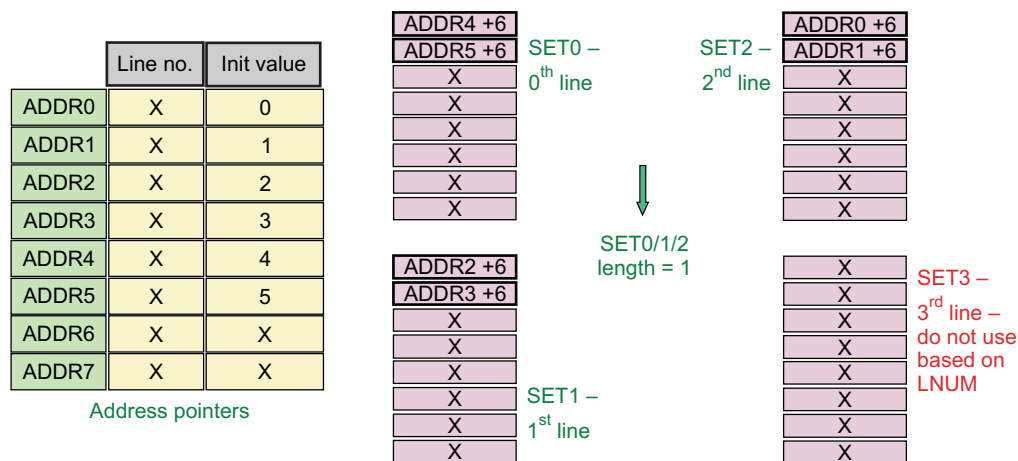

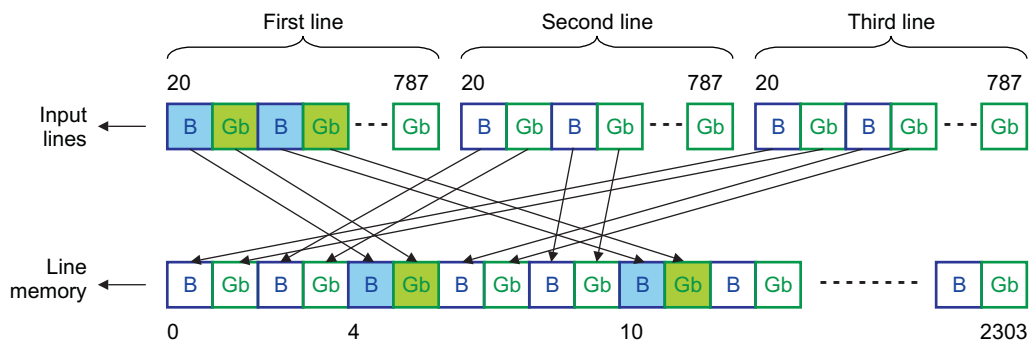

Figure 8-199 is an example that shows the register setting.

- Multiple input lines combined into one output line (use three input lines to one output line in this example)
- Input -> 4, 5, 10, 11, ..., 2, 3, 8, 9, ..., 0, 1, 6, 7, ... (three lines read from sensor)
- Output -> 0, 1, 2, 3, ... (1 line output)
- Register settings:

- ISIF\_FMTCFG[0] FMTEN = 0x1
- ISIF\_FMTCFG[1] FMTCBL = 0x1
- ISIF\_FMTCFG[11:8] FMTAINC = 0x5 (add or subtract 6)
- ISIF\_FMTCFG[5:4] LNUM = 0x2
- SETs recycled based on LNUM

**Figure 8-199. ISS ISP ISIF Example of Combining Three Input Lines Into a Single Line**

camss-131

### 8.3.3.7.7 ISS ISP ISIF Color Space Converter

**Figure 8-200. ISS ISP ISIF Color Space Converter Block Diagram**

The color space converter (CSC) includes four 8-bit × 12-bit multipliers and one adder for the color space conversion. These multiplier/adder units are used for the operation described in Figure 8-201. Data are taken from two input lines during the operation.

Coefficients are signed 8-bit (decimal is 5 bits). Coefficients are set through the following registers:

- Coefficient M00: [ISIF\\_CSCM0\[7:0\]](#) CSCM00
- Coefficient M01: [ISIF\\_CSCM0\[15:8\]](#) CSCM01
- Coefficient M02: [ISIF\\_CSCM1\[7:0\]](#) CSCM02
- Coefficient M03: [ISIF\\_CSCM1\[15:8\]](#) CSCM03
- Coefficient M10: [ISIF\\_CSCM2\[7:0\]](#) CSCM10
- Coefficient M11: [ISIF\\_CSCM2\[15:8\]](#) CSCM11
- Coefficient M12: [ISIF\\_CSCM3\[7:0\]](#) CSCM12
- Coefficient M13: [ISIF\\_CSCM3\[15:8\]](#) CSCM13
- Coefficient M20: [ISIF\\_CSCM4\[7:0\]](#) CSCM20
- Coefficient M21: [ISIF\\_CSCM4\[15:8\]](#) CSCM21
- Coefficient M22: [ISIF\\_CSCM5\[7:0\]](#) CSCM22
- Coefficient M23: [ISIF\\_CSCM5\[15:8\]](#) CSCM23
- Coefficient M30: [ISIF\\_CSCM6\[7:0\]](#) CSCM30
- Coefficient M31: [ISIF\\_CSCM6\[15:8\]](#) CSCM31
- Coefficient M32: [ISIF\\_CSCM7\[7:0\]](#) CSCM32
- Coefficient M33: [ISIF\\_CSCM7\[15:8\]](#) CSCM33

**Figure 8-201. ISS ISP ISIF Color Space Converter Operation**

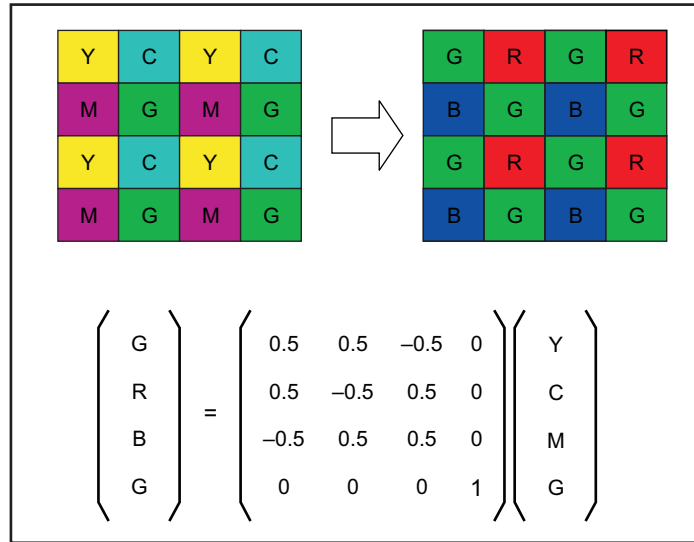

$$\begin{pmatrix} Out1 \\ Out2 \\ Out3 \\ Out4 \end{pmatrix} = \begin{pmatrix} M00 & M01 & M02 & M03 \\ M10 & M11 & M12 & M13 \\ M20 & M21 & M22 & M23 \\ M30 & M31 & M32 & M33 \end{pmatrix} \begin{pmatrix} In1 \\ In2 \\ In3 \\ In4 \end{pmatrix}$$

M00–M33: Signed 8-bit data with 5-bit decimal  
the value range  $-4 \leq M_{xx} < 4$

camss-618

The CSC can convert CMYG filtered CCD data to Bayer matrix (RGBG) data, as shown in Figure 8-202.

**Figure 8-202. ISS ISP ISIF Color Space Converter Operation: CMYG to RGBG**

camss-113

Figure 8-203 through Figure 8-205 show which input pixels are used for the operation. There is one-line latency between the input and the output.

**Figure 8-203. ISS ISP ISIF Color Space Conversion Example**

camss-114

**Figure 8-204. ISS ISP ISIF 1st Pixel/1st Line Generation**

camss-115

**Figure 8-205. ISS ISP ISIF 2nd Pixel/1st Line Generation**

camss-116

As shown in Figure 8-206 through Figure 8-209, the operation for the last pixel and the second last pixel uses the same input data.

**Figure 8-206. ISS ISP ISIF 2nd Last Pixel/1st Line Generation**

camss-117

**Figure 8-207. ISS ISP ISIF Last Pixel/1st Line Generation**

camss-118

**Figure 8-208. ISS ISP ISIF 1st Pixel/Last Line Generation**

camss-119

**Figure 8-209. ISS ISP ISIF 2nd Pixel/Last Line Generation**

camss-120

Also, the operation for the last line and the second last line uses the same input data (see [Figure 8-210](#) and [Figure 8-211](#)).

**Figure 8-210. ISS ISP ISIF 2nd Last Pixel/Last Line Generation**

camss-121

**Figure 8-211. ISS ISP ISIF Last Pixel/Last Line Generation**

camss-122

In addition to the registers specific to the color space converter, some of the registers are shared with the input data formatter to configure the valid area:

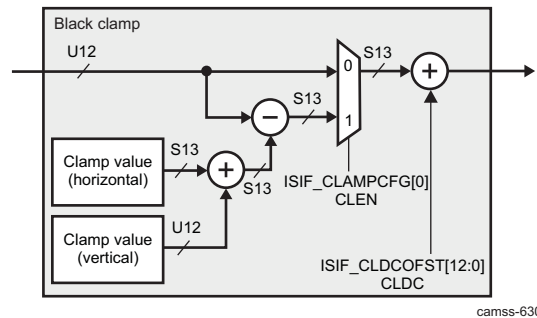

- [ISIF\\_FMTSPH](#)
- [ISIF\\_FMTLNH](#)
- [ISIF\\_FMTLSV](#)
- [ISIF\\_FMTLNV](#)

There must be at least 1 invalid pixel at the end of the line and one invalid line at the end of the frame.

To enable the color space conversion, set the [ISIF\\_CSCCTL\[0\]](#) CSCEN bit to 1.

### 8.3.3.7.8 ISS ISP ISIF Black Clamp

**NOTE:** For the memory access locations of the ISIF clamp, see [Section 8.3.3.9](#).

**Figure 8-212. ISS ISP ISIF Black Clamp Block Diagram**

The clamp value is calculated based on the pixel value of the OB region of the sensor. The clamp value is calculated separately for horizontal and vertical directions to compensate the offset drift in both horizontal and vertical directions. The sum of the horizontal and vertical clamp values is subtracted from the image data, and then the additional DC offset is added (the `ISIF_CLDCOFST[12:0]` CLDC bit field, an S13Q0 value). This value is added whether the black clamp module is enabled or not.

The horizontal clamp is disabled through the `ISIF_CLAMPPCFG[2:1]` CLHMD bit field.

To enable the black clamp module, set the `ISIF_CLAMPPCFG[0]` CLEN bit to 1. The `ISIF_PPLN[15:0]` PPLN bit field sets the pixel per line, and the number of pixel clock periods in one line HD period equals `PPLN + 1` pixel clock. The `ISIF_PPLN[15:0]` bit field is not used when the input is already HD/VD.

#### 8.3.3.7.8.1 ISS ISP ISIF Clamp Value for Horizontal Direction

The clamp value for horizontal direction is calculated using the pixel values at the upper OB region.

The maximum pixel value to be used for the clamp value calculation can be limited to 1023 if the pixel value limitation is enabled (`ISIF_CLHWIN0[6]` CLHLMT = 1).

Clamp value calculation for horizontal direction can be disabled in case there is no upper OB region. The operating modes are:

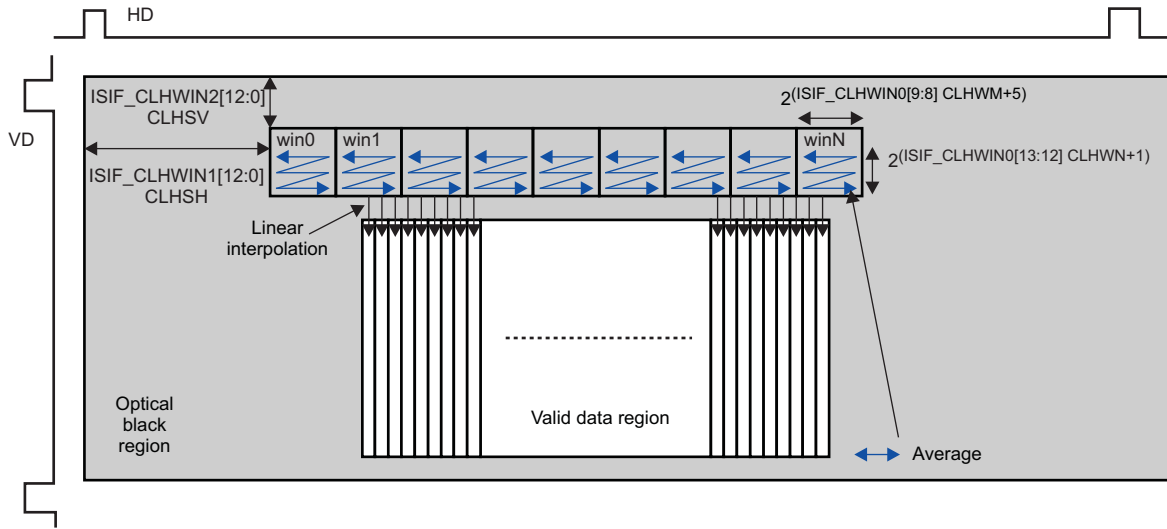

- Horizontal clamp value calculation is enabled. The calculated horizontal clamp value is subtracted from the image data along with the vertical clamp value (`ISIF_CLAMPPCFG[2:1]` CLHMD = 0x1).
- Horizontal clamp value is not updated. The horizontal clamp value used for the previous image is subtracted from the image data along with the vertical clamp value (`ISIF_CLAMPPCFG[2:1]` CLHMD = 0x2).
- Horizontal clamp value is not updated. Only the vertical clamp value is subtracted from the image data (`ISIF_CLAMPPCFG[2:1]` CLHMD = 0x0).

The number of windows in a row is set with the `ISIF_CLHWIN0[4:0]` CLHWC bit field.

Up to 32 windows in a row can be set for clamp value calculation. All the windows have the same size in a format  $2^{(ISIF\_CLHWIN0[9:8] \text{ CLHWM}+5)}$  pixels by  $2^{(ISIF\_CLHWIN0[13:12] \text{ CLHWN}+1)}$  lines.

The `ISIF_CLHWIN2[12:0]` CLHSV and `ISIF_CLHWIN1[12:0]` CLHSH bit fields enable setting the position of the first optical black clamp window in the frame. The pixel and line offset are in a range [0:8191]. The `ISIF_HDW` register sets the width of the HD.

Figure 8-213. ISS ISP ISIF Clamp Value for Horizontal Direction

Windows settings details

camss-132

The clamp value for horizontal direction calculation steps is:

1. Calculate the average of the pixel value in each window (ave\_win<sub>0</sub> to ave\_win<sub>N</sub>).

Calculation Steps	win0	win1	win2	...	wini	wini + 1	...	winN
Average of the pixel value	ave_win <sub>0</sub>	ave_win <sub>1</sub>	ave_win <sub>2</sub>		ave_win <sub>i</sub>	ave_win <sub>i+1</sub>		ave_win <sub>N</sub>

2. Set the average of the left-most window or the right-most window as the base value B<sub>V</sub>:

- B<sub>V</sub> = ave\_win<sub>0</sub> (if ISIF\_CLHWIN0[5] CLHWBS = 0x0, case 1)
- B<sub>V</sub> = ave\_win<sub>N</sub> (if ISIF\_CLHWIN0[5] CLHWBS = 0x1, case 2)

3. Subtract the base value from the average of each window. Use this value as a clamp value for each window.

Calculation Steps	win0	...	wini	wini+1	...	winN
Clamp value for each window	clamp_win <sub>0</sub> = ave_win <sub>0</sub> - B <sub>V</sub>		clamp_win <sub>i</sub> = ave_win <sub>i</sub> - B <sub>V</sub>	clamp_win <sub>i+1</sub> = ave_win <sub>i+1</sub> - B <sub>V</sub>		clamp_win <sub>N</sub> = ave_win <sub>N</sub> - B <sub>V</sub>

4. Acquire the horizontal distance (X and CLHWM - X) from the valid pixel to be processed to the center of the closest two windows.
5. Calculate the clamp value of the valid pixel by linear interpolation, using the clamp value of the closest two windows (i and i + 1).
  - Case 1: interpolated\_clamp\_win<sub>X</sub> = (clamp\_win<sub>i+1</sub> - clamp\_win<sub>i</sub>) \* X / CLHWM
  - Case 2: interpolated\_clamp\_win<sub>X</sub> = (clamp\_win<sub>i</sub> - clamp\_win<sub>N</sub>) \* (CLHWM - X) / CLHWM +

$$(\text{clamp\_win}_{i+1} - \text{clamp\_win}_N) * X / \text{CLHWM}$$

6. If the valid pixel is on the left of the center of the left-most window, the clamp value of the left-most window is applied. If the valid pixel is on the right of the center of the right-most window, the clamp value of the right-most window is applied.

The clamp values calculated (A), (B) and (C) are:

- Case1: Base is win0 (Left-most window: [ISIF\\_CLHWIN0\[5\]](#) CLHWBS = 0x0)
  - (A): zero
  - (B):  $(\text{clamp\_win}_{i+1} - \text{clamp\_win}_i) * X / \text{CLHWM}$
  - (C):  $(\text{clamp\_win}_N - \text{clamp\_win}_0)$
- Case2: Base is winN (Right-most window: [ISIF\\_CLHWIN0\[5\]](#) CLHWBS = 0x1)
  - (A):  $(\text{clamp\_win}_0 - \text{clamp\_win}_N)$
  - (B):  $(\text{clamp\_win}_i - \text{clamp\_win}_N) * (\text{CLHWM} - X) / \text{CLHWM} + (\text{clamp\_win}_{i+1} - \text{clamp\_win}_N) * X / \text{CLHWM}$
  - (C): zero

Each interpolated value  $\text{interpolated\_clamp\_win}_x$  is then subtracted to the associated column.

### 8.3.3.7.8.2 ISS ISP ISIF Clamp Value for Vertical Direction

The clamp value for vertical direction is calculated using the pixel values at the left or right OB region. Line average is calculated for the OB H valid period ( $2^{(\text{ISIF\_CLVWIN0}[2:0] \text{CLVOBH} + 1)}$ ). The averages for the previous lines are also added back to reduce the difference between the lines, as shown in [Figure 8-214](#).

**Figure 8-214. ISS ISP ISIF Clamp Value for Vertical Direction Calculation**

camss-619

- Clamp Value ( $V_n$ ) = Line Average ( $V_n$ ) \* k + Clamp Value ( $V_1$ ) \* (1-k)
- k = [ISIF\\_CLVWIN0\[15:8\]](#) CLVCOEF

The position of the first vertical black clamp window is set with the [ISIF\\_CLVWIN2\[12:0\]](#) CLVSV and [ISIF\\_CLVWIN1\[12:0\]](#) CLVSH bit fields. The number of vertical windows is set with the [ISIF\\_CLVWIN3\[12:0\]](#) CLVOBV bit field. [ISIF\\_VDW](#) sets the width of the VD.

The accumulator, which holds the vertical clamp value for the previous line, is reset at the beginning of the OB V valid. The reset value can be selected through the [ISIF\\_CLVWIN0\[5:4\]](#) CLVRVSL bit field:

- [ISIF\\_CLVWIN0\[5:4\]](#) CLVRVSL = 0x0: The base value is calculated for horizontal direction (left-most window win0 or right-most winn set with [ISIF\\_CLHWIN0\[5\]](#) CLHWBS).
- [ISIF\\_CLVWIN0\[5:4\]](#) CLVRVSL = 0x1: The base value is set through the configuration register ([ISIF\\_CLVRV\[11:0\]](#) CLVRV).
- [ISIF\\_CLVWIN0\[5:4\]](#) CLVRVSL = 0x2: No update (same as the previous image)

The following figures show the OB valid settings and associated vertical clamp value calculation when OB region is at the left (see [Figure 8-215](#)) and when OB region is at the right (see [Figure 8-216](#)). Each line average value is subtracted from the associated line valid region data.

Figure 8-215. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Left

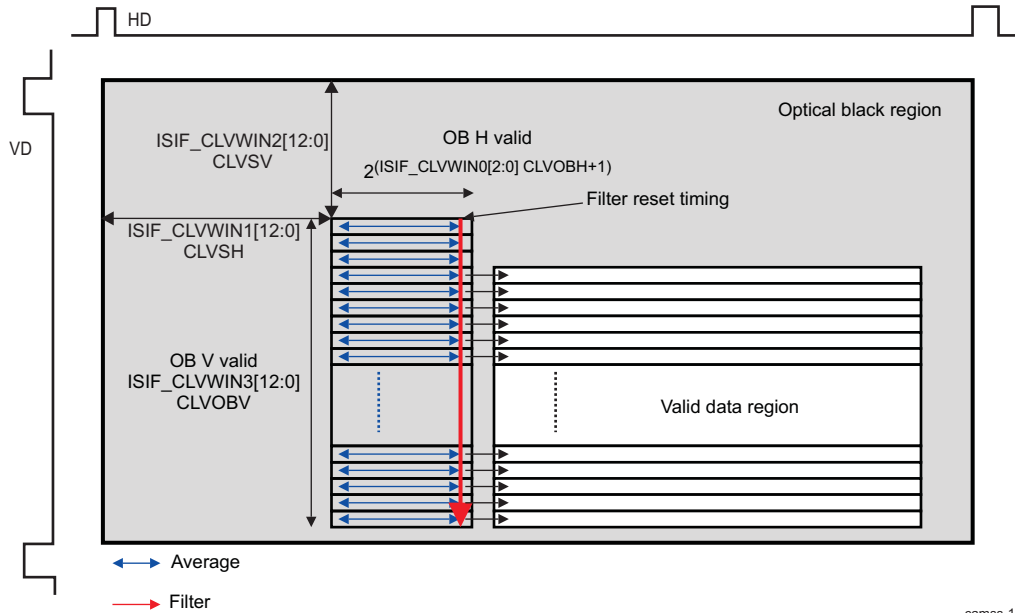

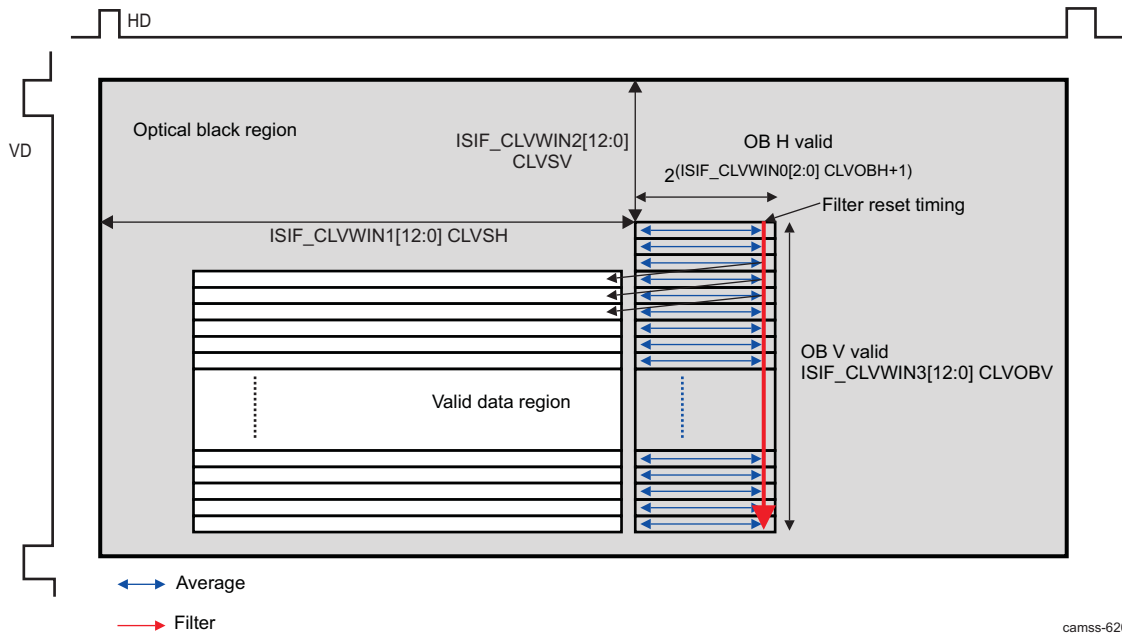

Figure 8-216. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Right

8.3.3.7.9 ISS ISP ISIF Vertical Line Defect Correction (VDFC)

Figure 8-217 shows the block diagram of the vertical line defect (VDFC) correction.

**Figure 8-217. ISS ISP ISIF Vertical Line Defect Correction Block Diagram**

The VDFC block can correct up to eight vertical line defects (see [Figure 8-218](#)).

**Figure 8-218. ISS ISP ISIF Vertical Line Defects**

The correction method is common to all the defects and can be selected through the `ISIF_DFCCTL[6:5]` VDFCSL bit field.

There are two different methods to correct vertical line defects (`ISIF_DFCCTL[6:5]` VDFCSL):

- Method 1: Data is replaced by an average (`ISIF_DFCCTL[6:5]` VDFCSL = 0x2):
  - The defect is replaced by the average of pixel (i - 2) and pixel (i + 2)
- Method 2: Data is subtracted by a defect level (`ISIF_DFCCTL[6:5]` VDFCSL = 0x0 or 0x1):
  - A saturation level is defined in the `ISIF_VDFSATLV[11:0]` VDFSLV bit field.
  - The coordinates of the defect:
    - Are defined in the `ISIF_DFCMEM0[12:0]` DFCMEM0 and `ISIF_DFCMEM1[12:0]` DFCMEM1 bit fields
    - Are 13 bits wide for horizontal and vertical direction, so an image size up to 8192 x 8192 is supported
  - If the data is not saturated (data < VDFSLV):
    - The defect is corrected by subtracting the defect level. A different defect level is defined for:
      - The point of the defect (V = Vdefect): SUB1 defect level is defined in the `ISIF_DFCMEM2[7:0]` DFCMEM2 bit field.
      - The pixels lower than the defect (V < Vdefect): SUB2 defect level is defined in the `ISIF_DFCMEM3[7:0]` DFCMEM3 bit field.
      - The pixels upper than the defect (V > Vdefect): Defect level is defined in the `ISIF_DFCMEM4[7:0]` DFCMEM4 bit field.
    - Each defect level (value to be subtracted from the data) described previously can be up-shifted through the `ISIF_DFCCTL[10:8]` VDFLSFT bit field.
    - Vertical line defect correction for upper pixels can be disabled through the `ISIF_DFCCTL[7]` VDFCUDA bit.
  - If the data is saturated (VDFSLV), there are two possibilities:
    - `ISIF_DFCCTL[6:5]` VDFCSL = 0x0: Data is simply fed through (not subtracted).
    - `ISIF_DFCCTL[6:5]` VDFCSL = 0x1: Horizontal interpolation  $((i - 2) + (i + 2))/2$  (data is replaced by

interpolation or data is subtracted with interpolation)

The [ISIF\\_LPFR](#) register sets the number of half lines per frame or field:  $VD \text{ period} = (L \text{ PFR} + 1)/2$  lines. LPFR is not used when HD and VD are inputs.

The following paragraphs concern only method 2 correction.

The coordinates of the defects and the defect levels to be subtracted from the data must be set to the processing shown in [Table 8-344](#).

**Table 8-344. ISS ISP ISIF Vertical Line Defect Table in Memory**

Bit	Defect Information
12:0	Vertical position of the defects
25:13	Horizontal position of the defects
33:26	Defect level of the vertical line defect position ( $V = V_{\text{defect}}$ )
41:34	Defect level of the pixels upper than the vertical line defect ( $V < V_{\text{defect}}$ )
49:42	Defect level of the pixels lower than the vertical line defect ( $V > V_{\text{defect}}$ )

The defect must be set from left to right, as shown in [Figure 8-219](#).

**Figure 8-219. ISS ISP ISIF Vertical Line Defects**

camss-135

Vertical line defect correction is enable by setting the [ISIF\\_DFCCTL\[4\]](#) VDFCEN bit to 1, but the procedure explained in [Section 8.3.3.7.9.1](#), *ISS ISP ISIF Vertical Line Defect Table Update Procedure*, must be respected.

**8.3.3.7.9.1 ISS ISP ISIF Vertical Line Defect Table Update Procedure**

The following procedure must be respected to write the vertical line defect table in memory.

1. [ISIF\\_DFCMEMCTL\[4\]](#) DFCMCLR = 0x1
2. Ensure that [ISIF\\_DFCCTL\[4\]](#) VDFCEN is disabled (0x0).
3. Write the V coordinate of the first defect to the [ISIF\\_DFCMEM0\[12:0\]](#) DFCMEM0 bit field.
4. Write the H coordinate of the first defect to the [ISIF\\_DFCMEM1\[12:0\]](#) DFCMEM1 bit field.
5. Set the defect level to:
  - [ISIF\\_DFCMEM2\[7:0\]](#) DFCMEM2
  - [ISIF\\_DFCMEM3\[7:0\]](#) DFCMEM3
  - [ISIF\\_DFCMEM4\[7:0\]](#) DFCMEM4
6. Set the [ISIF\\_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF\\_DFCMEMCTL\[2\]](#) DFCMARST bit set to 1.
7. Wait until the [ISIF\\_DFCMEMCTL\[0\]](#) DFCMWR bit is cleared.
8. Write the next data to:
  - [ISIF\\_DFCMEM0\[12:0\]](#) DFCMEM0

- [ISIF\\_DFCMEM1\[12:0\]](#) DFCMEM1
  - [ISIF\\_DFCMEM2\[7:0\]](#) DFCMEM2
  - [ISIF\\_DFCMEM3\[7:0\]](#) DFCMEM3
  - [ISIF\\_DFCMEM4\[7:0\]](#) DFCMEM4
9. Set the [ISIF\\_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF\\_DFCMEMCTL\[2\]](#) DFCMARST bit cleared.
  10. Repeat 4~5 times until all entries (up to 8) are written to the vertical line defect table.
  11. In case the defect entry is less than 8, an extra write cycle is required to fill the next table location with a certain value.
  12. Clear the [ISIF\\_DFCMEM0\[12:0\]](#) DFCMEM0 bit field to all 0, set the [ISIF\\_DFCMEM1\[12:0\]](#) DFCMEM1 to all 1, and set the [ISIF\\_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF\\_DFCMEMCTL\[2\]](#) DFCMARST bit cleared.
  13. Enable VDFC by setting the [ISIF\\_DFCCTL\[1\]](#) VDFCEN bit.

### 8.3.3.7.10 ISS ISP ISIF Lens Shading Correction (2D-LSC)

**NOTE:** For the memory access locations of the 2D-LSC table, see [Section 8.3.3.9](#).

**Figure 8-220. ISS ISP ISIF 2D-LSC Block Diagram**

LSC is useful for correcting optical artifacts that cause image brightness to decrease starting from the center of the image and going out to the edges.

The LSC module implements a per pixel offset and gain adjustment in the RAW Bayer domain (2 × 2 color pattern). The offset is applied before gain multiplication.

The offset and gains are stored in a LUT, which is stored in SDRAM and is loaded in real time. The submodule prefetches the data from SDRAM such that no underflow occurs. Underflow occurs when the offset and gain data required for the current pixel are not available.

The data stored in the LUT is downsampled; that is, there is no gain or offset per pixel. The downsampling factor is programmable. High downsampling ratios lead to a smaller LUT, lower accuracy, and lower memory bandwidth. A low downsampling ratio leads to a bigger LUT, higher accuracy, and higher memory bandwidth.

When the offset and gain values are loaded, they are upsampled to the incoming image resolution. The missing table values are computed through bilinear interpolation.

To enable the 2D-LSC module, set the [ISIF\\_2DLSCCFG\[0\]](#) ENABLE bit to 1.

#### 8.3.3.7.10.1 ISS ISP ISIF 2D-LSC Active Region Settings

The gain and offset maps are internally up-sampled to full resolution before being applied to the image. In order to account for all the possible cropping schemes and zoom ratios, the 2D-LSC can be configured such that a single gain map can be stored in memory that maps to sensor lens. The 2D-LSC active region is defined by [Figure 8-221](#).

Figure 8-221. ISS ISP ISIF 2D-LSC Active Region for ISIF Input Frame

camss-621

#### 8.3.3.7.10.1.1 ISS ISP ISIF 2D-LSC Gain and Offset Tables

The gain and offset map are MxN downsampled:

- M is the horizontal sampling factor.
- N is the vertical sampling factor.
- M and N are {8, 16, 32, 64, 128} independently.
- $N = M$ . M is set in the [ISIF\\_2DLSCCFG\[14:12\] GAIN\\_MODE\\_M](#) bit field.
- N is set in the [ISIF\\_2DLSCCFG\[10:8\] GAIN\\_MODE\\_N](#) bit field.

The starting point of the preconfigured lens shading map can be modified in software to align with the ISIF input image frame. The location of the gain and offset mask data in memory is specified by :

- For gain map:
  - Table base address: [ISIF\\_2DLSCGRBU\[15:0\] BASE31\\_16](#) and [ISIF\\_2DLSCGRBL\[15:0\] BASE15\\_0](#)
- For offset map:
  - Table base address: [ISIF\\_2DLSCORBU\[15:0\] BASE](#) and [ISIF\\_2DLSCORBL\[15:0\] BASE](#)

The input address must be aligned to a 4-byte boundary.

In the full resolution case, the address is set to the beginning of the map. When the LSC active region is defined over a cropped region of the full image, the SDRAM input address can be set to the upper-left corner of the grid closest to the beginning of the active region, and the [ISIF\\_2DLSCINI\[6:0\] X](#) and [ISIF\\_2DLSCINI\[14:8\] Y](#) bit fields mark the offset into the upsampled gain and offset map where the active region begins. [Figure 8-222](#) shows the LSC active region with respect to the gain and offset map grid. Because (X, Y) deals with the pixel phase inside a gain and offset map grid, X and Y must each be less than M and N, respectively.

Before applying the gain or offset table, the table is internally upsampled and interpolated back to full resolution via bilinear interpolation.

**Figure 8-222. ISS ISP ISIF Gain and Offset Mask Upsampling via Bilinear Interpolation**

The gain table format is set in the [ISIF\\_2DLSCCFG\[3:1\] GAIN\\_FORMAT](#) bit field. 8-bit entries are supported in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0 to shift the range up).

8-bit entries are supported in the offset map (in S8Q0 format). An optional shifting up for offsets is possible. The shift up value is selected through the [ISIF\\_2DLSCOFST\[6:4\] OFSTSFT](#) bit field. A scaling factor for offsets is defined in the [ISIF\\_2DLSCOFST\[15:8\] OFSTSF](#) bit field.

The offset control in the 2D-LSC module can be enabled or disabled through the [ISIF\\_2DLSCOFST\[0\] OFSTEN](#) bit.

For an LSC active region size of  $W \times H$  (the output and input are the same size), and the gain and offset maps are  $M \times N$  downsampled, a table with the following values is needed:

- $(\text{ceil}[(X + W) / M] + 1) \times (\text{ceil}[(Y + H) / N] + 1) \times 4$  bytes data in external memory organized as:
  - $(\text{ceil}[(\text{Init}X + W) / M] + 1)$  lines of data
  - Each line having at least  $(\text{ceil}[(\text{Init}Y + H) / N] + 1) \times 4$  data points

Extra data at end of each line can be skipped by the line offset register parameter:

- For gain map:
  - Line offset: [ISIF\\_2DLSCGROF\[15:0\] OFFSET](#)
- For offset map:
  - Line offset: [ISIF\\_2DLSCOROF\[15:0\] OFFSET](#)
- Each line offset must start at a 32-bit aligned boundary.

#### 8.3.3.7.10.1.2 ISS ISP ISIF 2D-LSC Gain and Offset Table Upsampling

Upsampling of the pixel-by-pixel gains is performed by locating the four same-color anchors for each destination gain value and applying bilinear interpolation.

The gain and offset mask function is neutral to color pattern. The starting color of the gain and offset mask must be consistent with the starting color of the image, and can be any color. To align starting colors, the X and Y values must be even. The 2D-LSC engine upsamples each phase of the mask data as a separate plane and applies the upsampled mask to the image with the same color phasing. In other words, the red gains are interpolated with red gains, and applied to the red input pixels. The same is done for each of the other three colors in the color pattern. The 2D-LSC module is designed to work with Bayer CFA data, having the R/Gr/Gb/B color pattern. For the purpose of functional description, assume red is the starting color, but any other starting color or other 2 x 2 pattern can be used by placing color gains in the appropriate order.

### 8.3.3.7.10.1.3 ISS ISP ISIF Application of Gain and Offset to Image Pixels

The gain value interpolated for each pixel is multiplied with a corresponding input pixel. An offset is applied before the gain. The product is rounded to the nearest integer and then clipped or saturated to the valid range of 13 bits.

The following equation describes the operation of the LSC in terms of offset and gain:

$$\text{out}[x,y] = (\text{in}[x,y] + a * (\text{ofst}[x,y] \ll T)) * \text{gain}[x,y] \quad (6)$$

- in[x, y] are the input pixels, 13 bits signed.
- ofst[x, y] are the upsampled offset points.
- T is the upshift value applied to the result of the offset interpolation points (0 – 5) set through the [ISIF\\_2DLSCOFST\[6:4\] OFSTSFT](#) bit field.
- a is the offset gain value in U8Q7 format set through the [ISIF\\_2DLSCOFST\[15:8\] OFSTSF](#) bit field.
- gain[x, y] are the upsampled gain points.
- out[x, y] are the resulting output pixels, 13 bits signed.

### 8.3.3.7.10.1.4 ISS ISP ISIF Enabling/ Disabling the 2D-LSC Module

LSC operates on a single frame or continuously, depending on the firmware programming.

Upon power-on reset (POR), the 2D-LSC module is disabled and input pixels are copied to the output, bypassing any shading operation.

When enabling or disabling the 2D-LSC, caution must be taken on the timing of register modifications. To avoid causing a prefetch error or other unexpected behavior, the following safeguards must be implemented:

1. While configuring the 2D-LSC registers, the input clock into the ISIF should be toggling.
2. All of the 2D-LSC registers must be configured appropriately before enabling the [ISIF\\_2DLSCCFG\[0\] ENABLE](#) bit.
3. After setting the ENABLE bit to 1, the hardware immediately begins fetching the first two rows of gain and offset data entries from external memory. When this is complete, the [ISIF\\_2DLSCIRQST\[2\] PREFETCH\\_COMPETED](#) status flag is set.

---

**NOTE:** If the ENABLE bit is disabled before the [ISIF\\_2DLSCIRQST\[3\] SOF](#) status flag is set, the [ISIF\\_2DLSCIRQST\[1\] PREFETCH\\_ERROR](#) flag is set and the state of the 2D-LSC submodule may lead to unexpected errors. Therefore, the ENABLE bit must not be disabled until after the [ISIF\\_2DLSCIRQST\[3\] SOF](#) status flag is set.

---

4. Appropriate gains and offsets are applied to the image pixels. Pixels outside the LSC active region are passed through unaltered. When the 2D-LSC operation on the active region completes, the [ISIF\\_2DLSCIRQST\[0\] DONE](#) status flag is set.
5. At this point:
  - If the ENABLE bit is still set to 1, the hardware immediately begins to prefetch the gain and offset data entries for the next frame and waits for the active region of the next frame to arrive.
  - If the ENABLE bit is set to 0, it stops LSC operation once the active region is passed, and goes into idle until the ENABLE bit is written to 1 again.

---

**NOTE:** To provide a mechanism for firmware to recover from the LSC module waiting indefinitely for the input image, if LSC\_ENABLE is written to 0 after it has started gain/offset map prefetching, but before the LSC gets to the next active region, the LSC operation is aborted and turned idle, and any prefetched gain/offset entries are discarded. This can happen before or after the next start-of-frame.

---

**NOTE:** Therefore, because of the constraints set in point 3, the ENABLE register bit must be disabled only after the [ISIF\\_2DLSCIRQST\[3\]](#) SOF status flag is set and before the [ISIF\\_2DLSCIRQST\[0\]](#) DONE status flag is set for that same frame.

It is suggested that when the 2D-LSC or the whole ISIF needs to be disabled for switching modes, the [ISIF\\_2DLSCIRQST\[3\]](#) SOF interrupt be enabled so that software knows when it is safe to disable the 2D-LSC. Then the ISIF can be disabled after the [ISIF\\_2DLSCIRQST\[0\]](#) DONE status signal is set for that frame.

---

**NOTE:** The LSC\_ENABLE bit, once written to 1, must not be cleared until at least one vpi\_clk clock cycle after start-of-frame, to ensure correct processing.

---

#### 8.3.3.7.10.1.5 ISS ISP ISIF 2D-LSC Events and Status Checking

The 2D-LSC submodule can generate events on a single interrupt line. These events are further remapped at the ISP level in `ISP5_IRQENABLE_SET__0.ISIF_INT_3` - `ISP5_IRQENABLE_SET__3.ISIF_INT3`.

Four 2D-LSC events can be generated:

- **DONE:** LSC done. This event triggers when the LSC submodules transition from ACTIVE state to IDLE state.
- **PREFETCH\_ERROR:** Gain table prefetch error. This event triggers when the tables stored in SDRAM are read too slowly. After this event is asserted, the LSC disables the LSC computation until the beginning of the next frame.
- **PREFETCH\_COMPLETE:** Gain table prefetch complete. This event triggers when data prefetching from SDRAM completes. Data prefetching must complete by the time the first pixel of a frame comes. The event triggers when the buffer contains three full rows of data.
- **SOF:** This event signals the start of the LSC valid region. The LSC configuration registers for the next frame can be updated after the LSC SOF triggers.

The [ISIF\\_2DLSCIRQEN](#) register can be configured to select which events are masked and which are propagated to the LSC interrupt signal. The [ISIF\\_2DLSCIRQST](#) register can be read and cleared to identify which events have occurred.

In addition, the 2D-LSC module provides the following status bit:

- **BUSY:** This indicates that LSC has entered the active region vertically. This bit remains on during horizontal blanking, and turns off only after the entire active region of the current frame is processed.

#### 8.3.3.7.10.1.6 ISS ISP ISIF Supported On-the-Fly 2D-LSC Configurations

The 2D-LSC prefetch memory is equal to  $2 \times 1536 \times 32$  bits. This memory is sized to fetch three lines of 8-bit gain and 8-bit offset  $\times$  four color components per paxel. Given an image sensor of horizontal resolution H, there are  $\text{floor}[(H / \text{ISIF\_2DLSCCFG}[14:12] \text{ GAIN\_MODE\_M}) + 1]$  paxels per line, where M is the horizontal LSC paxel size.

[Table 8-345](#) shows the LSC horizontal paxel size, which can be supported for different image sensor resolutions. When  $M = 8$ , some resolutions cannot be supported on the fly (orange-shaded cells in the table); the way to process such large images is to use vertical frame division.

Table 8-345. ISS ISP ISIF Supported On-the-Fly LSC Configurations

MPix	Aspect Ratio		Line Size	Horizontal LSC Pixel Size: $M = 2^{\lfloor \text{ISIF\_2DLSCCFG}[14:12] \text{ GAIN\_MODE\_M} \rfloor}$				
				8	16	32	64	128
Maximum	–	–	5376	2019	1011	507	255	129
16	16	9	5333	2003	1003	503	253	128
16	4	3	4619	1735	869	436	220	111
16	3	2	4899	1840	922	462	233	118

8	3	2	3464	1302	653	328	165	84

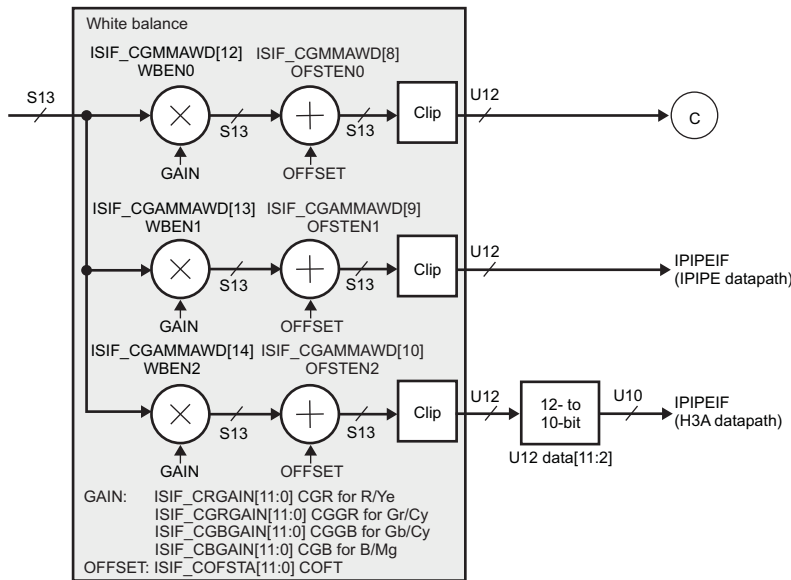

8.3.3.7.10.1.7 ISS ISP ISIF Bandwidth Requirements on BL Read Port

See Section 8.3.3.7.18.2 for details.

8.3.3.7.11 ISS ISP ISIF White Balance

Figure 8-223 shows the white balance block diagram.

Figure 8-223. ISS ISP ISIF White Balance Block Diagram

Color pattern settings are set through the **ISIF\_CCOLP** register. Moreover, through this register the pixel position from 0 to 3 can be set to the needed Bayer universal camera filter color pattern (RGB/CYGM).

The CFA pattern can be in two modes, stripe or mosaic, and is set through the **ISIF\_CGAMMAWD[5]** CFAP bit.

There are color-dependent gain controls for the three outputs: BL output, IPIPEIF (IPIPE path) output, and IPIPEIF (H3A path) output. Gain applied to each data is selected according to the pixel position and the color pattern settings. Gain factors are common for the three data paths. Gain is in U11Q9 format, which ranges from 0 to 3 + 511/512. The gain factor is set through the following registers:

- R/Ye gain: [ISIF\\_CRGAIN\[11:0\]](#) CGR
- Gr/Cy gain: [ISIF\\_CGRGAIN\[11:0\]](#) CGGR
- Gb/Cy gain: [ISIF\\_CGBGAIN\[11:0\]](#) CGGB
- B/Mg gain: [ISIF\\_CBGAIN\[11:0\]](#) CGB

Gain control can be enabled or disabled individually for each path.

- Enable or disable gain for the BL path: [ISIF\\_CGAMMAWD\[12\]](#) WBEN0.
- Enable or disable gain for the IPIPEIF (IPIPE) path: [ISIF\\_CGAMMAWD\[13\]](#) WBEN1.
- Enable or disable gain for the IPIPEIF (H3A) path: [ISIF\\_CGAMMAWD\[14\]](#) WBEN2.

After the gain control, a single offset value can be added to each path individually. This offset is common for the three paths and is set through the [ISIF\\_COFSTA\[11:0\]](#) COFT bit field. The offset value is U12, which ranges from 0 to 4095. Data (S13) are then truncated to U12.

- Enable or disable offset for the BL path: [ISIF\\_CGAMMAWD\[8\]](#) OFSTEN0.
- Enable or disable offset for the IPIPEIF (IPIPE) path: [ISIF\\_CGAMMAWD\[9\]](#) OFSTEN1.

### 8.3.3.7.12 ISS ISP ISIF Low-Pass Filter (LPF)

Figure 8-224 shows the low-pass filter block diagram.

**Figure 8-224. ISS ISP ISIF Low-Pass Filter Block Diagram**

An optional horizontal low-pass anti-aliasing filter (LPF) can be applied (the [ISIF\\_MODESET\[14\]](#) HLPF bit) after reframing. The low-pass filter consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

---

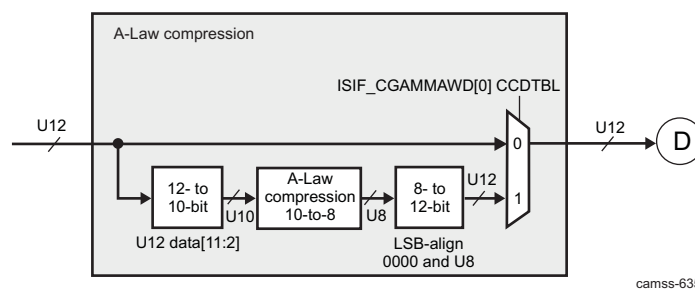

**NOTE:** For YUV data, the LPF must be disabled ([ISIF\\_MODESET\[14\]](#) HLPF = 0x0).

---

### 8.3.3.7.13 ISS ISP ISIF A-Law Compression

Figure 8-225 shows the A-Law compression block diagram.

**Figure 8-225. ISS ISP ISIF A-Law Compression Block Diagram**

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied (`ISIF_CGAMMAWD[0]` CCDTBL) as the final processing stage. Using this compression causes the data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected (`ISIF_CGAMMAWD[4:1]` GWDI).

The IPIPEIF module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

---

**NOTE:** Do not use A-Law compression (`ISIF_CGAMMAWD[0]` CCDTBL = 0) with YUV data.

---

Figure 8-226 shows the A-Law table diagram, and Figure 8-227 shows the A-Law table values.

**Figure 8-226. ISS ISP ISIF A-Law Table Diagram**

Figure 8-227. ISS ISP ISIF A-Law Table Values

**8.3.3.7.14 ISS ISP ISIF Culling**

Figure 8-228 shows the culling block diagram.

**Figure 8-228. ISS ISP ISIF Culling Block Diagram**

The culling block performs a programmable decimation function for horizontal, vertical, and YUV4:2:2 data directions. The horizontal and vertical decimation of image data can be controlled by two registers.

The horizontal culling operation allows selected pixel data to be culled (deleted) from a line. The [ISIF\\_CULH](#) register specifies the horizontal culling pattern for even and odd lines:

- Even lines: [ISIF\\_CULH](#)[15:8] CLHE
- Odd lines: [ISIF\\_CULH](#)[16:0] CLHO

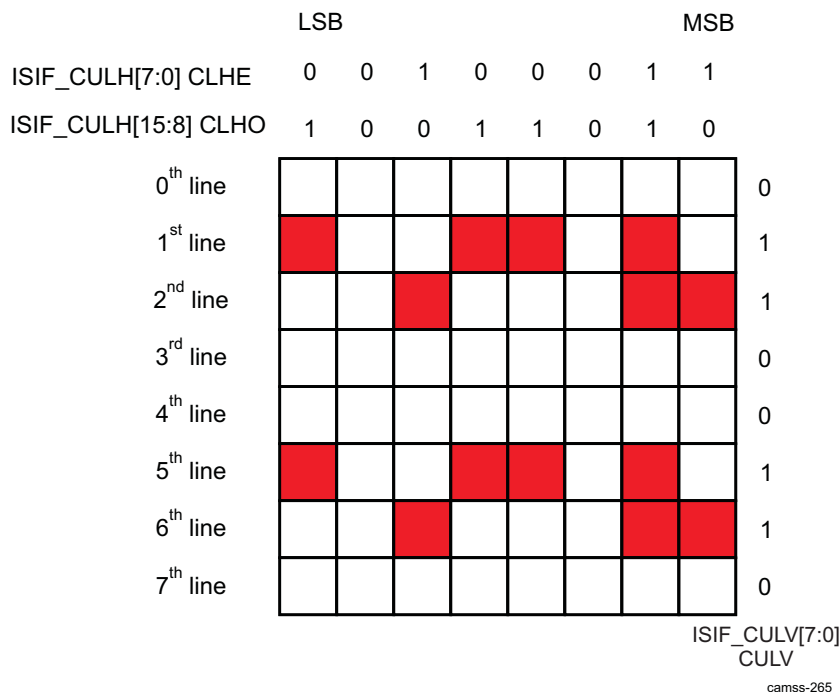

The vertical culling operation allows selected lines to be culled from a frame. The [ISIF\\_CULV](#) register specifies the pattern for the vertical direction. The LSBs of CULV represent the top line of the CCD; the MSB is the seventh line.

[Figure 8-229](#) is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example,  $CULH = 0x59C4$  and  $CULV = 0x0066$ .

---

**NOTE:** Culling can be used with YUV data, but care must be taken to preserve the YUV4:2:2 output format.

---

**Figure 8-229. ISS ISP ISIF Example for Decimation Pattern**

### 8.3.3.7.15 ISS ISP ISIF 12-to-8 bit DCPM Compression Block

In ISIF, there is a DPCM compression block, which is between the culling module and the storage formatter module. This block can compress 12-bit image data to 8 bits for bandwidth reduction in transmission between the ISIF and SDRAM. An 8- to-12-bit DPCM decoder at the IPIPEIF decompresses data for IPIPE processing.

Two different predictors are used for the compression system. The first predictor is simple (simple predictor), and the second predictor is slightly more complex (advanced predictor). Because the advanced predictor gives a slightly better prediction for the pixel value, the image quality can be improved using it. Because the simple predictor is very simple, the processing power and memory requirements are reduced using it, when the image quality is already sufficiently high.

- Advanced predictor: This predictor uses only the previous same color component value as a prediction value. Therefore, only 2-pixel memory is required.
- This predictor uses four previous pixel values when the prediction value is evaluated. This means that the other color component values are also used when the prediction value has been defined.

The function is controlled from the [ISIF\\_MISC\[12\] DPCMEN](#) and [ISIF\\_MISC\[13\] DPCMPRE](#) bits.

### 8.3.3.7.16 ISP ISIF Storage Formatter

Figure 8-230 shows the storage formatter block diagram.

**Figure 8-230. ISS ISP ISIF Storage Formatter Block Diagram**

Data are stored to the lower bits of a 16-bit SDRAM word, or can be 8- or 12-bit packed. The [ISIF\\_HSIZE\[11:0\]](#) HSIZE bit field can specify the memory address offsets between lines of memory (offset in 32-byte units). If set, the [ISIF\\_HSIZE\[12\]](#) ADCR bit can decrement the memory address line and the line can be horizontally flipped in memory.

In case of RAW data, a data shift module is used: data to be stored can be right-shifted according to the value set at the [ISIF\\_MODESET\[10:8\]](#) CCDW bit field, as described in [Table 8-346](#).

**Table 8-346. ISS ISP ISIF RAW Data Shifting**

ISIF_MODESET[10:8] CCDW	Output Format	
	MSB	LSB
000	0000 & U12 data[11:0]	
001	00000 & U12 data[11:1]	
010	000000 & U12 data[11:2]	
011	0000000 & U12 data[11:3]	
100	00000000 & U12 data[11:4]	

Table 8-347 shows the format where data are stored to the lower bits of a 16-bit word and the format where data are packed to 8 bits. The unused bits are filled with zeros.

**Table 8-347. ISS ISP ISIF SDRAM Data Format**

	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
12 bit	0	Pixel 1	0	Pixel 0
11 bit	0	Pixel 1	0	Pixel 0
10 bit	0	Pixel 1	0	Pixel 0
9 bit	0	Pixel 1	0	Pixel 0
8 bit	0	Pixel 1	0	Pixel 0
8-bit packed	Pixel 3	Pixel 2	Pixel 1	Pixel 0

Table 8-348 shows the format where data are packed to 12 bits.

**Table 8-348. ISS ISP ISIF SDRAM Data Format for 12-bit Packed**

	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
12 bit	Pixel2[7:0]	Pixel1	Pixel 0	
	Pixel5[3:0]	Pixel4	Pixel3	Pixel2[11:8]
	Pixel7	Pixel6	Pixel5[11:4]	

In case of YUV, YUV data is stored in memory in packed YUV4:2:2 mode, using 2 pixels per 32 bits, as shown in Table 8-349.

The output formatter can configure to any image format by using the SDRAM line offset register and offset control register ISIF\_SDOFST. Figure 8-231 shows how to construct a frame format in SDRAM. The ISIF\_CADU[10:0] CADU bit field specifies the memory destination (upper 11 bits) to SDRAM (the address is the value of the set bit multiplied by 32 bytes). On the other hand, the ISIF\_CADL[15:0] CADL bit field sets the memory destination to SDRAM (lower 16 bits) (the address is the value of the set bit multiplied by 32 bytes).

### 8.3.3.7.17 ISS ISP ISIF YCbCr signal Processing

The ISIF accepts 4:2:2 sampled YCbCr input data. The luminance and color difference signals are 8 bits each, scaled 0 to 255. The color difference signals are multiplexed into one 8-bit bus beginning with a Cb sample. The Y and CbCr buses can be input parallel (16-bit mode) or be time-multiplexed and input as a single bus (8-bit mode).

The 16- or 8-bit YCbCr data is stored in SDRAM as 4:2:2 format. Table 8-349 lists the data format in SDRAM. Y data typically has a range of 16 to 235; however, it is possible to subtract a DC value from the Y signal.

Table 8-349. ISS ISP ISIF Memory Output Format for YUV Data

Memory Address	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

### 8.3.3.7.18 ISS ISP ISIF Expected Bandwidth on BL Ports

The ISIF module has a write port and a read port connected to the BL. This section summarizes the expected bandwidth on these ports.

#### 8.3.3.7.18.1 ISS ISP ISIF Write Port

The write port is used to write pixels to memory after the data have passed through the storage formatter. Data storage to SDRAM is controlled by the [ISIF\\_SYNCEN\[1\]](#) DWEN bit. The module allows writing the data as 16, 12, and 8 bits per pixel. The bit width is controlled by the [ISIF\\_CCDCFG\[1:0\]](#) SDRPACK bit field.

The write port generates a burst of 32 bytes on the MTC interface. The delay between consecutive bursts is proportional to the input pixel clock. Hence, the write port does not request peak bandwidth traffic.

[Table 8-350](#) lists the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3 clock is 200 MHz.

**Table 8-350. ISP ISIF ISIF Module: Write Port Bandwidth**

Pixel Clock	Maximum Bandwidth 2 bytes/s pixel MB/s	Expected Delay Between MTC Requests
200	400	16 cycles = 80 ns
100	200	32 cycles = 160 ns
10	20	320 cycles = 1600 ns

#### 8.3.3.7.18.2 ISS ISP ISIF Read Port

The read port is used to read gain and offset data from SDRAM required for the LSC computation. When LSC is enabled, 8-bit gain values are read and 8-bit offset values can optionally also be read. The LSC gain computation can be enabled or disabled by setting the [ISIF\\_2DLSCCFG\[0\]](#) ENABLE bit. The LSC offset computation can be enabled by setting the [ISIF\\_2DLSCOFST\[0\]](#) OFSTEN bit.

The LSC submodule fetches four 8-bit gain values per paxel and optionally four 8-bit offset values per paxel. This is a maximum 8 bytes per paxel.

The bandwidth that is generated by the LSC module is also proportional to the paxel size. The paxel size is set up by the [ISIF\\_2DLSCCFG\[14:12\]](#) GAIN\_MODE\_M and [ISIF\\_2DLSCCFG\[10:8\]](#) GAIN\_MODE\_N bit fields. The possible values are 8, 16, 32, 64 and 128. Smaller values lead to higher memory bandwidth requirements. Hence, the worst case is achieved by setting an 8 × 8 paxel size.

When the LSC submodule is enabled it automatically prefetches two lines of gain values and two lines of offset values (if this is enabled). When the first VD comes, it again requests one line of gain values and one line of offset values (if this is enabled). Then, it again fetches one line of gain values and one line of offset values (if this is enabled) after [ISIF\\_2DLSCCFG\[10:8\]](#) GAIN\_MODE\_N lines. It continues to do so until the last row of paxels. For the last row of paxels, it fetch two lines of gain values and two lines of offset values (if this is enabled), which are used for the following frame.

By default, the LSC submodule creates peak bandwidth requirements. To avoid this, the MTC bandwidth limiter must be used to space the request over time.

The MTC bandwidth limiter must be used to smooth the bandwidth requirements of the LSC module. The MTC bandwidth limiter can be set with the [ISP5\\_BL\\_MTC\\_1.ISIF\\_R](#) register.

The principle is that instead of reading the gain and offset data as fast as possible, use the time that it takes for [ISIF\\_2DLSCCFG\[10:8\]](#) GAIN\_MODE\_N lines to pass through the ISP to read the data.

[Table 8-351](#) gives the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3 clock at 200 MHz.

**Table 8-351. ISS ISP ISIF Read Port Bandwidth**

Pixel Clock	Max Bandwidth MB/s	Expected Delay Between MTC Requests
200	25.07	255 cycles = 1275 ns
100	12.5	510 cycles = 2550 ns
10	1.25	5103 cycles = 2515 ns

When the bandwidth limiter is used, ensure that there is enough time for the data prefetching.

- The LSC submodule must be enabled at least  $2 \times$  [ISIF\\_2DLSCCFG\[10:8\] GAIN\\_MODE\\_N](#) lines before the first VD.
- There must be at least [ISIF\\_2DLSCCFG\[10:8\] GAIN\\_MODE\\_N](#) lines of blanking. If there is not enough blanking, multiply the bandwidth requirement by 2 (that is, ensure two lines of gain and offset data can be fetched within the time of [ISIF\\_2DLSCCFG\[10:8\] GAIN\\_MODE\\_N](#) lines).

**8.3.3.7.19 ISS ISP ISIF Events and Status Checking**

The ISIF module can generate four different interrupts: VDINT0, VDINT1, VDINT2, and 2DLSCINT. The [ISIF\\_SYNCEN\[0\] SYEN](#) bit must be enabled to receive any of the ISIF interrupts.

**8.3.3.7.19.1 ISS ISP ISIF VDINT0, VDINT1, and VDINT2 Interrupts**

As shown in [Figure 8-232](#), the VDINT0, VDINT1, and VDINT2 interrupts occur relative to the VD pulse. The trigger timing is selected by using the [ISIF\\_MODESET\[2\] VDPOL](#) bit setting. VDINT0, VDINT1, and VDINT2 occur after receiving the number of horizontal lines (HD pulse signals) set in the [ISIF\\_VDINT0\[14:0\] CDV0](#), [ISIF\\_VDINT1\[14:0\] CDV1](#), and [ISIF\\_VDINT2\[14:0\] CDV2](#) register fields, respectively.

**NOTE:** In the case of BT.656 input mode, there is a VD at the beginning of each field. Therefore, there are two interrupts for each frame (that is, one for each field).

If the [ISIF\\_MODESET\[2\] VDPOL](#) bit is set to 0, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the rising edge of the external VD.

**Figure 8-232. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 0**

camss-611

If the [ISIF\\_MODESET\[2\] VDPOL](#) bit is set to 1, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the falling edge of the external VD.

**Figure 8-233. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 1**

camss-612

**8.3.3.7.19.2 ISS ISP ISIF 2DLSCINT Interrupt**

See [Section 8.3.3.7.10.1.5](#) for more information.

### 8.3.3.7.19.3 ISS ISP ISIF Status Checking

The `ISIF_MODESET`[15] MDFS bit is set when the field status is on an even field, and it is cleared when the field status is on an odd field.

The 2D-LSC has a register that monitors the status of the LSC. See [Section 8.3.3.7.10.1.5](#) for more information.

## 8.3.3.8 ISS ISP BL Functional Description

### 8.3.3.8.1 ISS ISP BL Overview

The BL module arbitrates and merges the memory requests of the ISP master module. The BL module also generates interrupts upon frame completion for the following modules. The interrupt generation is delayed until the transfer completes (ack is returned). The following interrupts are delayed by the BL module:

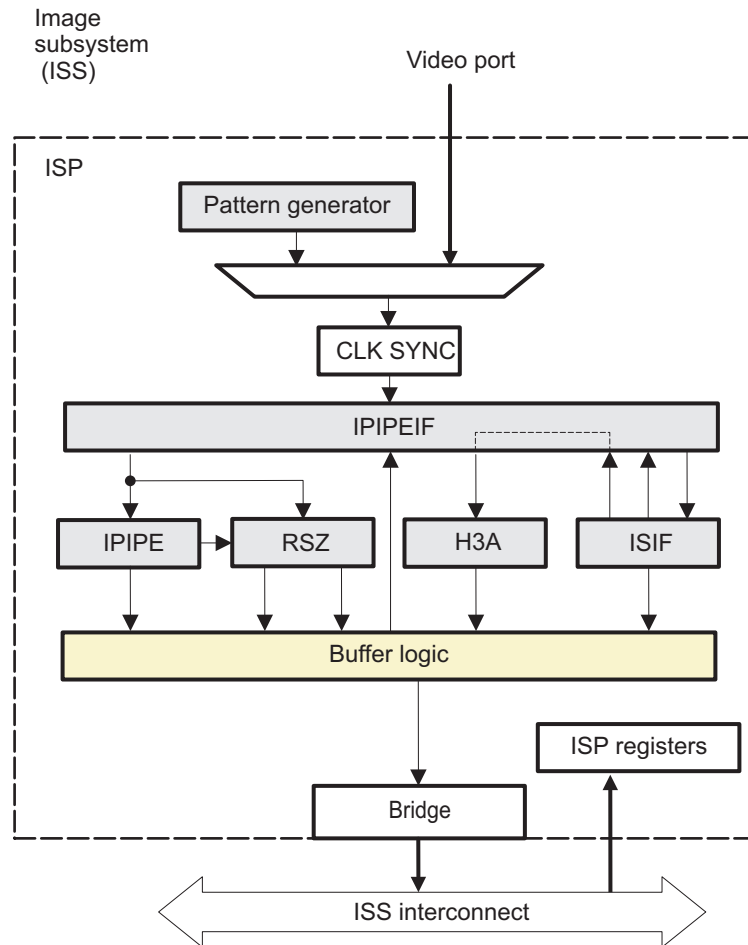

- RSZ module RSZ-A EOF
- RSZ module resizer RSZ-B EOF
- H3A module EOF
- IPIPE module EOF

The BL uses two different types of interfaces:

- MTC protocol is used between the ISP modules and the BL.
- VBUSM is use on the BL master port interface.

[Figure 8-234](#) show the BL module connections to other submodules of the ISP.

Figure 8-234. ISS ISP BL High-Level Diagram

camss-003f

### 8.3.3.8.2 ISS ISP BL Functional Description

The BL merges the memory requests of the ISP master module to memory (read/write). The BL interfaces with all the ISP modules through a 32-bit-wide bus following.

The ISP modules make memory requests of 32 bytes. Additional signals, SOF for read and EOF for write, are included to deal with boundary conditions in frame transitions.

The BL arbitration is divided into two parts: a bus hog and a fixed priority arbitration. Bus hog refers to the property of the buffer logic that gives higher priority to the module that last sent or received data. RESIZER module MTC write port 0 and RESIZER module MTC write port 1 are excluded from the bus hog.

The buffer logic is to be programmed to maximize the memory bandwidth: it makes maximum burst requests of 128 bytes (8 x 128 bits) for reads and writes. The BL can generate burst sizes of 2 x 128, 4 x 128, 6 x 128, and 8 x 128 bits.

**NOTE:** The ISP interface supports burst sizes of only 1, 2, 4, and 8 x 128 bits. If the BL generates a 6 x 128-bit request, it is broken into a 4 x 128-bit request, followed by another 2 x 128-bit request.

To use the memory bandwidth efficiently, the BL interfaces with the memory through a high-bandwidth bus (128 bits wide).

The BL handles memory requests for the following modules:

- IPIPEIF module read port
- ISIF-LSC module read port
- ISIF module write port
- IPIPE-BOXCAR module write port
- H3A module write port
- RESIZER module write port 0
- RESIZER module write port 1

From a use case point of view, the following sharing and priority arrangement is used. All reads have higher priority than writes; for reads: IPIPEIF > ISIF-LSC, and for writes: ISIF > IPIPE-BOXCAR > RESIZER #0 > RESIZER #1 > H3A.

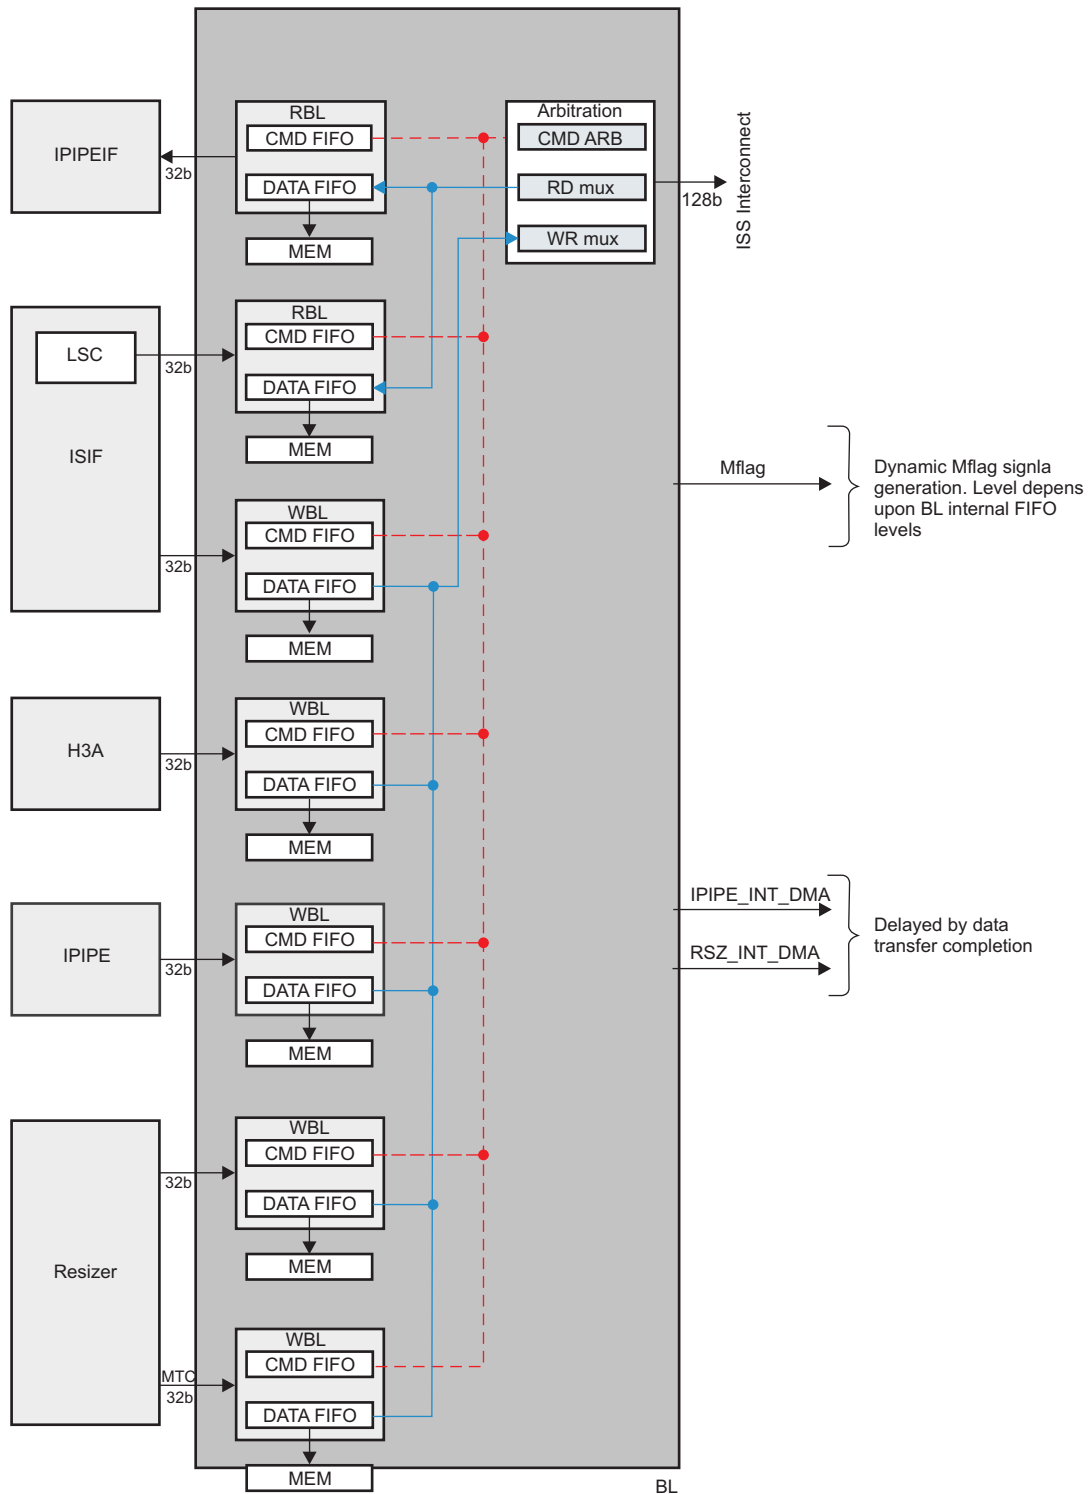

---

**NOTE:** BL can generate a static or a dynamic MFlag signal. The MFlag signal is used by the ISS arbitration to consider the urgency of the requests coming from the ISP. The dynamic MFlag feature is enabled from the [ISP5\\_CTRL\[21\] MFLAG](#) bit.

---

[Figure 8-235](#) shows the BL top-level block diagram. The figure highlights the two clock domains that are used.

Figure 8-235. ISS ISP BL Block Diagram

camss-080u

**NOTE:** The BL module has no registers. The configurations come from the top level of the ISP. See [Table 8-393](#) for register details.

### 8.3.3.8.3 ISS ISP BL Address Alignment

The BL module ensures maximum memory efficiency by realigning data to a 128-byte address boundary. In all cases, the BL accesses are 32-byte-aligned: address [4:0] is always 0.

This is required when the input address is a multiple of 32 bytes, not 128 bytes. The BL issues a non-aligned burst until it reaches a 128-byte boundary, and then keeps making a 128-byte request until the end of the line. Eventually, although the last burst in a line may not be a multiple of 128 bytes, it will always be a multiple of 32 bytes, as shown in [Figure 8-236](#).

**Figure 8-236. ISS ISP BL Address Alignment**

camss-687

### 8.3.3.8.4 ISS ISP BL Out-of-Order Responses

BL supports out-of-order responses. The out-of-order response is handled by having up to 16 outstanding CIDs (reads + writes). The maximum number of outstanding CIDs is set up by the `ISP5_CTRL[7:4]` `VBUSM_CIDS` bit field. There is one outstanding request per CID.

If any of the CIDs are not outstanding, a command is accepted from the highest prioritized buffer with a request. The CID availability is cleared when status complete is received. The outstanding commands can be all reads or all writes or any combination. The CID that is allocated is the lowest number of the 16 that are available when the command is accepted. As soon as a CID is released it is used if a command is available.

The `VBUSM2OCP` module transforms the `VBUSM` CIDs into `OCP MFlag` signals. Note that there can be only one outstanding per tag. It is not authorized to make a new request on a tag which is already waiting for a response.

### 8.3.3.8.5 ISS ISP BL Stalling

The BL can stall the requests from the initiator modules for reads and writes

#### 8.3.3.8.5.1 ISS ISP BL Stalling Write Requests

One reason for the BL to stall write requests is that there is usually back pressure on the system memory and requests cannot be issued as fast as required. In that case the BL must stall requests from the initiator modules. The BL module cannot know whether stalling the request will lead to an initiator overflow or not. The `RESIZER` module can support back pressure from the BL module when it is configured in bypass mode. The input buffer memory can be used to store data from the `IPIPE` and `IPIPEIF` modules. If the `RESIZER` input buffer overflows, an interrupt is issued.

#### 8.3.3.8.5.2 ISS ISP BL Stalling Read Requests

The BL may also stall read requests from the `ISIF-LSC` and `IPIPEIF` modules. When data comes from an image sensor there is no way to stop the sensor. If the read request is stalled too long, the `LSC` module may eventually underflow. When the `IPIPEIF` module reads all its data from memory, the `IPIPEIF` stalls transfers to successive modules by masking the clock.

### 8.3.3.8.6 ISS ISP BL Dynamic and Static MFlag Generation

**NOTE:** The following applies when `ISP5_CTRL[21] MFLAG = 1`. The MFlag value is static.

The BL outputs `cpriority[2:0]` and `cepriority[2:0]` signals on its VBUS master port interface. On the VBUSM side, these signals are aligned with the request (`creq`). Both values are actually repeating register input signals. The lower value (0) corresponds to the higher priority.

The MFlag signal does not need to be aligned with the request. The signal can change value anytime.

In the ISP VBUSM2 interface bridge, the `cepriority` signal is ignored and only the `cpriority` signal is used. Because the priority value is set up by a register setting, the value is not going to be dynamically modified obviously. [Table 8-352](#) shows how the `cpriority` values are mapped to the interface MFlag signal, which is present on the ISP master interface and set in the `ISP5_CTRL[3:1] VBUSM_CPRIORITY` bit field.

**Table 8-352. ISS ISP BL `cpriority` to MFlag With `ISP5_CTRL[21] MFLAG = 1`**

MFlag[1:0]	Description
00	Normal priority <code>cpriority[2:0] = 4, 5, 6, 7</code>
01	Medium priority <code>cpriority[2:0] = 2, 3</code>
10	Reserved
11	High priority <code>cpriority[2:0] = 0, 1</code>

**NOTE:** The following applies when the `ISP5_CTRL[21] MFLAG = 0`. The MFlag value is dynamic.

This feature is enabled at reset. The general idea for dynamic MFlag generation is to monitor the FIFO levels. Thresholds are used to increase or decrease the MFlag values. There are different implementations for read and write requestors.

An individual MFlag value is generated for each FIFO and then ORed altogether and exported at the BL boundary. The MFlag signal generation does not affect the BL arbitration scheme.

- Writes: To prevent overflows in the BL, dynamic MFlag signal generation gives higher priority to FIFOs that are almost full:
  - Low FIFO level = 50 percent
  - High FIFO level = 75 percent
  - FIFOs with more than 75 percent fill level have high priority: MFlag = 11
  - FIFOs between 50 and 75 percent fill level have medium priority: MFlag = 01
  - FIFOs below 50 percent fill level have normal priority: MFlag = 00

[Table 8-353](#) gives the low- and high-level priority thresholds for write initiators.

**Table 8-353. ISS ISP BL MFlag Write Low- and High-Level Priority Thresholds**

	ISIF	H3A	IPIPE	RSZ
Access type	Write	Write	Write	Write
Buffer size	64 x 128	64 x 128	48 x 128	64 x 136
50% low level	32 x 128	32 x 128	24 x 128	32 x 136
75% high level	48 x 128	48 x 128	36 x 128	48 x 128

- Reads: The dynamic MFlag signal generation depends on the reserved data units in the initiator data FIFO. The reserved data units correspond to read commands waiting to be sent on the interface bus, plus the read commands that have been sent on the interface bus and for which data responses have not yet arrived.
- The total FIFO size in bytes can be expressed as reserved data units (bytes) + data bytes stored (bytes) + empty space (bytes). By definition, empty space is lower than a burst size (128 bytes).
  - Low FIFO level = 25 percent

- High FIFO level = 50 percent
- Data bytes stored + empty space (bytes) = 50 percent of FIFO size: MFlag = 00
- Data bytes stored + empty space (bytes) 50 percent of FIFO size: MFlag = 01
- Data bytes stored + empty space (bytes) 25 percent of FIFO size: MFlag = 11

Table 8-354 gives the low- and high-level priority thresholds for read initiators

**Table 8-354. ISS ISP BL MFlag Read Low- and High-Level Priority Thresholds**

	IPIPEIF	ISIF-LSC
Access type	Read	Read
Buffer size	64 x 128	32 x 128
25% buffer size	16 x 128	8 x 128
50% buffer size	32 x 128	16 x 128

### 8.3.3.8.7 ISS ISP BL VBUSM2OCP Last Beat Command Delay

The VBUSM2OCP module bridge implements the following function to work around a limitation of the BL module, which does not send back-to-back requests to the ISS, thereby leading to possible situations where the ISP loses arbitration at the ISS level.

To fully benefit from dynamic MFlag generation (see Section 8.3.3.8.6), the following function is present in the VBUSM2OCP module bridge:

- The delay occurs only if BL MFlag = `ISP5_BL_VBUSM[5] MFLAG_THRES`.
- The MFlag value used is whatever is available when the last beat comes on the interface bus.
- The last beat of the interface request (read or write) is held until one cycle before a new command (read or write). This is achieved by masking the last beat of the interface command at the ISP interface.

The last beat is unmasked on the first event of one cycle before a new interface command, or the delay counter that uses the `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` value counter expires (has decremented to zero). The `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` bit field must be set before the request on the BL starts. If the value of the `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` bit field is changed during the pending requests, the delay counter is not updated.

### 8.3.3.8.8 ISS ISP BL Peak Memory Bandwidth Reduction

To limit the peak memory bandwidth generated by the IPIPEIF (read port), ISIF (read port), and H3A (write port) modules, a bandwidth limiter is placed between the modules and the BL. The resizer module has this function built in and therefore does not need a bandwidth limiter.

The bandwidth limiter enables control of the minimum interval between two consecutive memory requests.

This function is controlled by the `ISP5_BL_MTC_1` and `ISP5_BL_MTC_2` registers. When the registers are set to 0, the function is not modified (that is, the bandwidth limiter is disabled). For the resizer module, it is controlled by the following registers: `RSZ_DMA_RZA` and `RSZ_DMA_RZB`.

### 8.3.3.9 ISS ISP Memory Mapping

A total of 64KB is reserved for the ISP registers and memories. Table 8-355 describes the memory map.

**Table 8-355. ISS ISP Memory Mapping**

Memory Mapping	Start	End	Size	Comments
ISS ISP5 SYS1	0x5201 0000	0x5201 009F	160	ISP5 configuration registers (set 1)

### 8.3.4 ISS ISP Programming Model

**NOTE:** The preferred way to perform memory-to-memory processing with ISP is to use the CCP2 receiver module at the ISS level (see [Section 8.2, ISS Interfaces.](#)). It is possible to use the IPIPEIF read port for memory-to-memory processing, but it is not the preferred way because it does not provide enough granularity on the fractional clock divider for up to 20x digital zoom.

#### 8.3.4.1 ISS ISP PG Programming Model

The procedure in [Table 8-356](#) initializes the pattern generator.

**Table 8-356. ISS ISP PG Settings**

Step	Register/Bit Field/Programming Model	Value
Select the PG as the ISP source.	ISP5_PG[5:4] SRC_SEL	0x3
Select the mode for write-enable signal generation.	ISP5_PG[2] WEN	
Select the polarity of the horizontal sync signal.	ISP5_PG[1] HDPOL	
Select the polarity of the vertical sync signal.	ISP5_PG[0] VDPOL	
Sets the duration of the HD signal	ISP5_PG_PULSE_CTRL[12:0] HDW	
Sets the duration of the VD signal	ISP5_PG_PULSE_CTRL[27:16] VDW	
Sets the number of pixels per line	ISP5_PG_FRAME_SIZE[31:16] PPLN	
Sets the number of lines per frame	ISP5_PG_FRAME_SIZE[15:0] HLPFR	
Enables the pattern generator	ISP5_PG[3] EN	0x1

#### 8.3.4.2 ISS ISP ISIF Programming Model

This section discusses issues related to the software control of the ISIF. It lists the registers that are required to be programmed in different modes, describes how to enable and disable the ISIF and how to check the status of the ISIF, discusses the different register access types, and enumerates several programming constraints.

##### 8.3.4.2.1 ISS ISP ISIF Hardware Setup/Initialization

This section discusses the configuration of the ISIF required before image processing can begin.

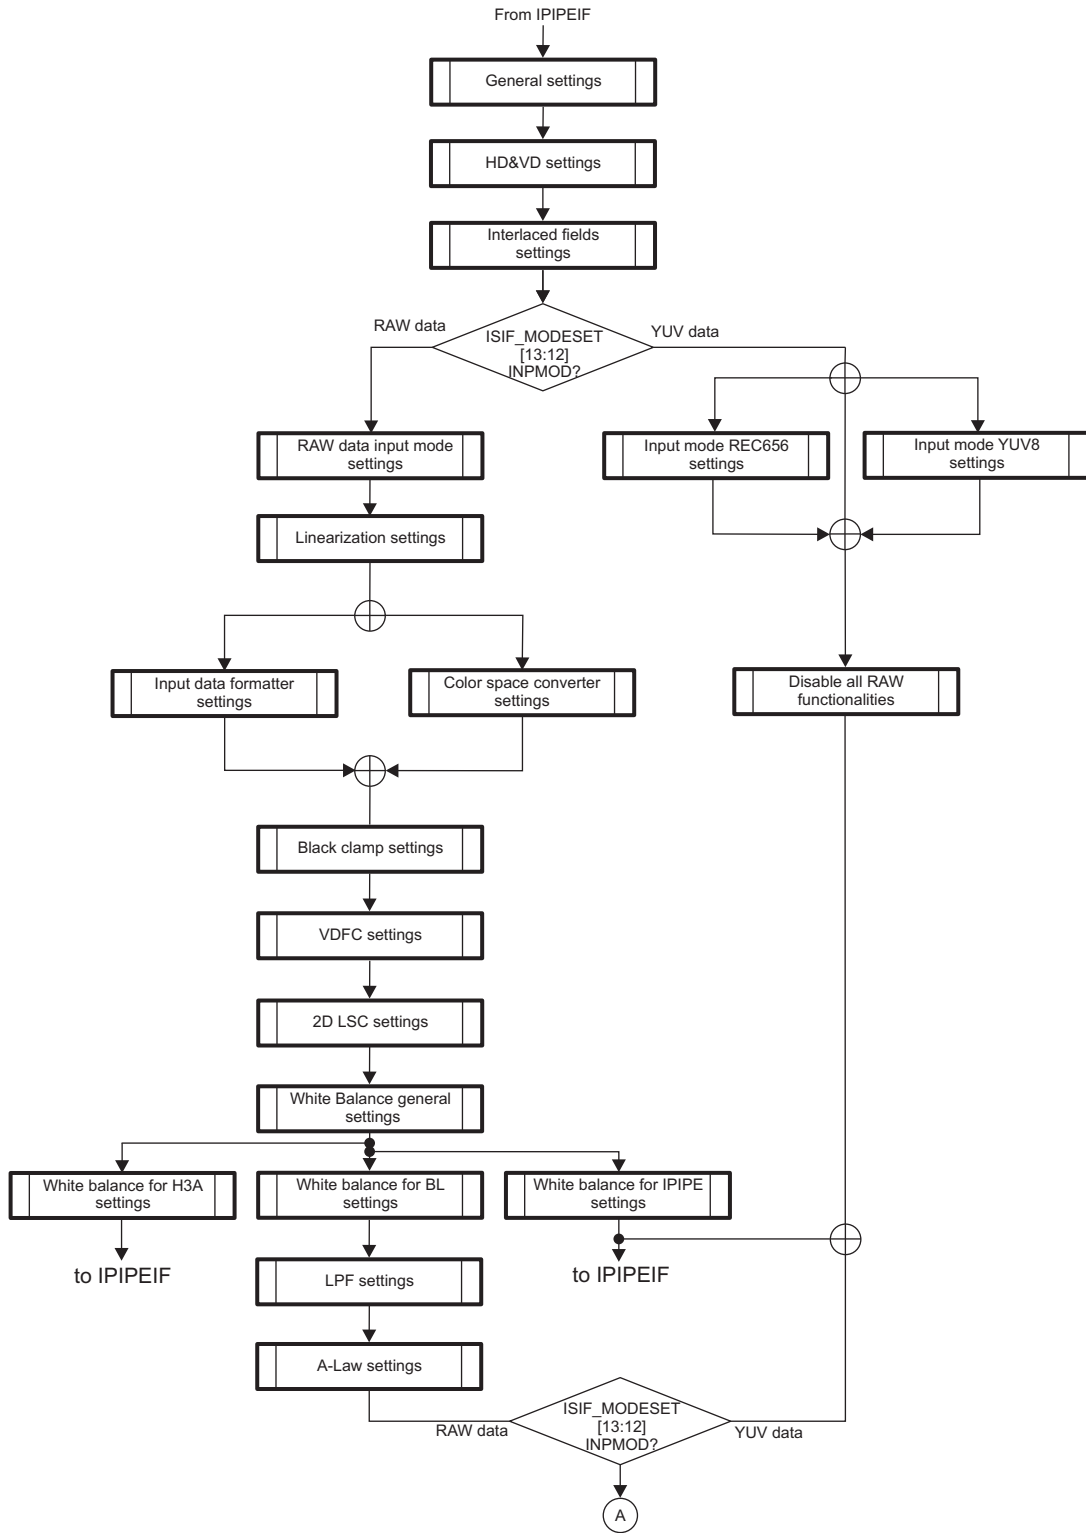

###### 8.3.4.2.1.1 ISS ISP ISIF Reset Behavior

Upon hardware reset of the ISP, all of the registers in the ISIF, except the defect table registers, are reset to their reset values. Because the defect table registers are stored in internal RAM, they do not have reset values. If the reset is a chip-level POR (reset after power is applied), the values of the defect table register are unknown. If the reset is an ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

###### 8.3.4.2.1.2 ISS ISP ISIF Register Setup

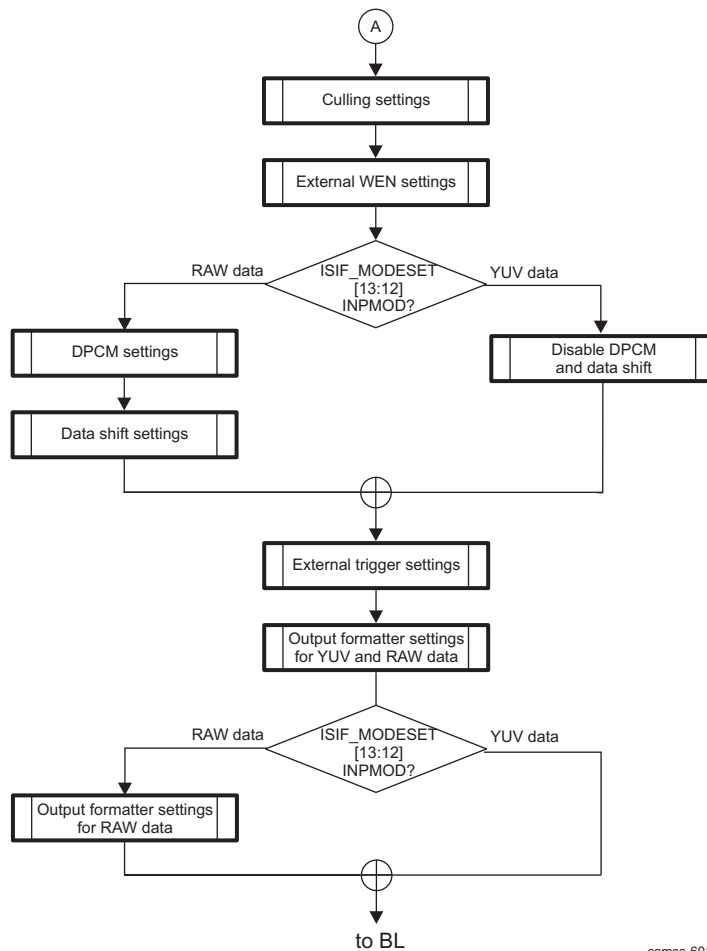

Before enabling the ISIF, the hardware must be properly configured through register writes. [Figure 8-237](#) and [Figure 8-238](#) show the sequence to be used for RAW and YUV data before enabling the ISIF. The register settings for each process in the following sequence are described in [Table 8-357](#).

Figure 8-237. ISS ISP ISIF Initialization Flow Chart – Part One

Select SDRAM pack mode.	ISIF_CCDCFG[1:0] SDRPACK	
Enable or disable VD/HD output.	ISIF_SYNCEN[0] SYEN	

### 8.3.4.2.2 ISS ISP ISIF Enable/Disable Hardware

The ISIF is enabled by setting the ISIF\_SYNCEN[0] SYEN bit. This is done after all the required registers discussed in the previous section are programmed.

With respect to the write enable bit and output address, the following procedure must be followed:

1. Set the data output address (ISIF\_CADU and ISIF\_CADL).
2. Enable HD/VD and WEN at the same time (ISIF\_MODESET[1] DWEN and ISIF\_SYNCEN[0] SYEN).

If the ISIF\_SYNCEN[0] SYEN bit is written before the output address and the SDRAM write enable bit (not recommended but may be required for a particular mode), data begins to be written to the old address value and not the one recently programmed. The desired response can be achieved if the following procedure is followed:

1. Enable HD/VD (ISIF\_SYNCEN[0] SYEN).
2. Set the output address (ISIF\_CADU and ISIF\_CADL).
3. Wait for the next VD.
4. Enable WEN (ISIF\_MODESET[1] DWEN).

The ISIF always operates in continuous mode. In other words, after enabling the ISIF, it continues to process sequential frames until the ISIF\_SYNCEN[0] SYEN bit is cleared by software. When this happens, the frame being processed is disabled immediately and does not continue to process the current frame.

When the HD/VD signals are set to outputs ( [ISIF\\_MODESET\[0\]](#) HDVDD = 0x1), fetching and processing of the frame begin immediately upon setting the [ISIF\\_SYNCEN\[0\]](#) SYEN bit.

When the HD/VD signals are set to inputs ( [ISIF\\_MODESET\[0\]](#) HDVDD = 0x0), processing of the frame is dependent on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the ISIF must be enabled before data transmission from the external device. In this way, the ISIF waits for data from the external device.

#### 8.3.4.2.3 ISS ISP ISIF Register Accessibility During Frame Processing

There are two types of register access in the ISIF:

- Shadowed registers (event latched registers)  
Shadowed registers are those that can be read and written at any time, but the written values take effect (are latched) only at certain times based on some event. Reads still return the most recent write even though the settings are not used until the specific event occurs.
- Busy-writable registers  
These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantly.

The following registers/fields can be set as shadow registers, or optionally set as busy-writable registers. When the [ISIF\\_CCDCFG\[15\]](#) VDLC bit is set to 0, these registers are shadowed; when the [ISIF\\_CCDCFG\[15\]](#) VDLC bit is set to 1, these registers are busy-writable. All other ISIF registers not included in this list are always busy-writable.

#### 8.3.4.2.4 ISS ISP ISIF Interframe Operations

Between frames, it may be necessary to enable or disable functions or to modify the memory pointers. Because the [ISIF\\_SYNCEN\[1\]](#) DWEN bit and the memory pointer registers are shadowed, these modifications can occur any time before the end of the frame and the data will be latched in for the next frame. Likewise, the 2D-LSC registers can be changed after receiving the LSC SOF interrupt but before it starts to prefetch the gain values for the next frame (the end of the LSC active region is reached). The host controller can perform these changes upon receiving an interrupt.

#### 8.3.4.2.5 ISS ISP ISIF Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the ISIF. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- PCLK cannot be higher than 200 MHz.
- If SDRAM output port is enabled:
  - The memory output line offset and address must be on 32-byte boundaries.
  - [ISIF\\_LNH\[14:0\]](#) LNH –1 must be a multiple of 32 bytes.
  - [ISIF\\_SPH](#), [ISIF\\_LNH](#), [ISIF\\_SLV0](#), [ISIF\\_SLV1](#), and [ISIF\\_LNV](#) must be cleared to 0 within the same VD period that the [ISIF\\_SYNCEN\[1\]](#) DWEN bit is cleared to 0.

- [ISIF\\_SPH](#), [ISIF\\_LNH](#), [ISIF\\_SLV0](#), [ISIF\\_SLV1](#), and [ISIF\\_LNV](#) must be set from 0 to the appropriate values within the same VD period that the [ISIF\\_SYNCEN\[1\]](#) DWEN bit is set to 1.
- In RAW input mode:
  - [ISIF\\_CCDCFG\[4\]](#) YCINSWP must be set to 0.
- If DPCM compression is enabled:
  - Horizontal culling must not be used. Use the input formatter instead.
- For 2D-LSC:
  - $N \leq M$  (where M = horizontal downsampling factor, N = vertical downsampling factor)
  - The [ISIF\\_2DLSCINI](#) register values must be even numbers.
  - Maximum widths with respect to selected M value (see [Table 8-358](#))

**Table 8-358. ISS ISP ISIF Maximum Line Width Versus M Value**

M	Maximum Line Width
8	2040
16	4080
32	8160
64	16,320
128	16,384

### 8.3.4.3 ISS ISP IPIPEIF Programming Model

This section discusses issues related to the software control of the IPIPEIF module. It lists the registers that are required to be programmed in different modes, describes how to enable and disable the IPIPEIF module and how to check the status of the IPIPEIF module, discusses the different register access types, and enumerates several programming constraints.

#### 8.3.4.3.1 ISS ISP IPIPEIF Hardware Setup/Initialization

This section discusses the configuration of the IPIPEIF module required before image processing can begin.

##### 8.3.4.3.1.1 ISS ISP IPIPEIF Reset Behavior

Upon hardware reset of the ISP ([ISP5\\_SYSCONFIG\[1\]](#) SOFTRESET = 0x1), all the registers in the IPIPEIF are reset to their reset values.

##### 8.3.4.3.1.2 ISS ISP IPIPEIF Register Setup

Before enabling the IPIPEIF, the hardware must be properly configured through register writes. [Table 8-359](#) identifies the register parameters that must be programmed before enabling the IPIPEIF module (depending on the functions needed).

**Table 8-359. ISS ISP IPIPEIF Required Configuration Parameters**

Step	Configuration Required	Value
General settings		
Select the input sources for IPIPEIF.	<a href="#">IPIPEIF_CFG1[15:14]</a> INPSRC1 <a href="#">IPIPEIF_CFG1[3:2]</a> INPSRC2	
Select VD sync polarity.	<a href="#">IPIPEIF_CFG2[2]</a> VDPOL	
Select HD sync polarity.	<a href="#">IPIPEIF_CFG2[1]</a> HDPOL	
Select the interrupt source.	<a href="#">IPIPEIF_CFG2[0]</a> INTSW	
Select the input clock source.	<a href="#">IPIPEIF_CFG1[10]</a> CLKSEL	
Set the clock divider value.	<a href="#">IPIPEIF_CLKDIV[15:0]</a> CLKDIV	
Set the data type: YUV or RAW.	<a href="#">IPIPEIF_CFG2[3]</a> YUV16	

**Table 8-359. ISS ISP IPIPEIF Required Configuration Parameters (continued)**

Step	Configuration Required	Value
Settings to perform if data is from BL		
Set HD setting.	IPIPEIF_PPLN[12:0] PPLN	
Set VD setting.	IPIPEIF_LPFR[12:0] LPFR	
Set the number of valid pixels in a line.	IPIPEIF_HNUM[12:0] HNUM	
Set the number of valid lines.	IPIPEIF_VNUM[12:0] VNUM	
Set memory address information.	IPIPEIF_ADDRU[10:0] ADDRU IPIPEIF_ADDRL[15:0] ADDRL IPIPEIF_ADOFS[11:0] ADOFS	
Set one-shot mode, if needed.	IPIPEIF_CFG1[0] ONESHOT	
Use SYNCOFF function only for double-buffering. See <a href="#">Section 8.3.3.3.2.1</a> for details.	IPIPEIF_ENABLE[1] SYNCOFF	
Settings to perform for RAW data from ISIF or BL		
Select the unpack function.	IPIPEIF_CFG1[9:8] UNPACK	
Settings to perform for YUV for data from ISIF		
Set the data type to YUV.	IPIPEIF_CFG2[3] YUV16	
If YUV16 = 0x1, enables or not the conversion from 8 bits to 16 bits	IPIPEIF_CFG2[6] YUV8	
If YUV16 = 0x1, set the way the data is unpacked.	IPIPEIF_CFG2[7] YUV8P	
DCPM function		
Enable or disable DPCM decompression.	IPIPEIF_DPCM[0] ENA	
Select DPCM prediction mode.	IPIPEIF_DPCM[1] PRED	
Select DPCM bit mode.	IPIPEIF_DPCM[2] BITS	
Select inverse A-Law function.	IPIPEIF_CFG1[9:8] UNPACK	
Select SDRAM read data shift. - For RAW data - DPCM enabled and A- Law disabled - or DPCM disabled	IPIPEIF_CFG1[13:11] DATASFT	
Dark frame subtraction (DFS) function		
Set defect pixel correction (DPC1) for VP or ISIF inputs.	RAW data from VP (video port), BL(buffer logic, SDRAM) or ISIF	
Set the associated threshold for DPC1.	IPIPEIF_DPC1[12] ENA	
Set the associated threshold for DPC1.	IPIPEIF_DPC1[11:0] TH	
Set defect pixel correction (DPC2) for BL inputs.	IPIPEIF_DPC2[12] ENA	
Set the associated threshold for DPC1.	IPIPEIF_DPC2[11:0] TH	
Set the direction of subtraction.	IPIPEIF_CFG2[5] DFSDIR	
Set the averaging filter, horizontal pixel decimator, and gain function for IPIPE data path.		
Enable averaging filter function.	IPIPEIF_CFG1[7] AVGFILT	
Enable horizontal pixel decimation function.	IPIPEIF_CFG1[1] DECIM	
Set horizontal resizing value.	IPIPEIF_RSZ[6:0] RSZ	
Set the resizer initial position.	IPIPEIF_INIRSZ[13] ALNSYNC IPIPEIF_INIRSZ[12:0] INIRSZ	
Set the data gain (only for RAW data).	IPIPEIF_GAIN[9:0] GAIN	
Set the output clipping value.	IPIPEIF_OCLIP[11:0] OCLIP	

**Table 8-359. ISS ISP IPIPEIF Required Configuration Parameters (continued)**

Step	Configuration Required	Value
Set the averaging filter and horizontal pixel decimator function for H3A data path.		
Enable averaging filter function.	IPIPEIF_RSZ3A[8] AVGFILT	
Enable horizontal pixel decimation function.	IPIPEIF_RSZ3A[9] DECIM	
Set horizontal resizing value.	IPIPEIF_RSZ3A[6:0] RSZ	
Set the resizer initial position.	IPIPEIF_RSZ3A[13] ALNSYNC IPIPEIF_RSZ3A[12:0] INIRSZ	

For information about YUV data coming and unpacking from the ISIF module, see [Section 8.3.3.3.13](#).

#### 8.3.4.3.2 ISS ISP IPIPEIF Enable/Disable Hardware

When IPIPEIF\_CFG1[ 15:14] INPSRC1 or IPIPEIF\_CFG1[3:2] INPSRC2 = 0, the IPIPEIF does not need to be enabled: it receives data from the VP and pushes it to the ISIF, H3A, IPIPE, and RESIZER modules.

If IPIPEIF\_CFG1[ 15:14] INPSRC1 or IPIPEIF\_CFG1[3:2] INPSRC2 ≠ 0, the IPIPEIF module begins to fetch data from the BL by setting the IPIPEIF\_ENABLE[0] ENABLE bit. Writing the enable bit must be the last step of the configuration.

When the input source is the BL, the IPIPEIF can optionally operate in one-shot mode or continuous mode by setting the IPIPEIF\_CFG1[0] ONESHOT parameter. If one-shot mode is enabled, then after enabling the IPIPEIF, the IPIPEIF\_ENABLE[0] ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begins immediately upon setting the IPIPEIF\_ENABLE[0] ENABLE bit.

When the input source is the ISIF, processing of the frame is dependent on the timing of the ISIF. To ensure that data from the ISIF is not missed, the IPIPEIF must be enabled before the ISIF. In this way, the IPIPEIF waits for data from the ISIF.

When the IPIPEIF is in continuous mode, it can be disabled by clearing the IPIPEIF\_ENABLE[0] ENABLE bit after processing of the last frame. The disable takes place immediately because it is a busy-writable register.

An EOF interrupt can indicate to other modules that the frame treatment is finished. See [Section 8.3.3.3.15](#) for more information.

#### 8.3.4.3.3 ISS ISP IPIPEIF Register Accessibility During Frame Processing

There are two types of register access in the IPIPEIF:

- Shadow registers

These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame (VD rising edge). Reads still return the most recent write even though the settings are not used until the next start of frame. The following are the shadowed registers in the IPIPEIF:

IPIPEIF_PPLN	IPIPEIF_ADDRU	IPIPEIF_CFG1[1] DECIM
IPIPEIF_HNUM	IPIPEIF_ADOFS	IPIPEIF_CFG1[7] AVGFILT
IPIPEIF_VNUM	IPIPEIF_ENABLE[1] SYNCOFF	IPIPEIF_RSZ
IPIPEIF_GAIN	IPIPEIF_RSZ3A[9] DECIM	IPIPEIF_RSZ3A[8] AVGFILT
IPIPEIF_RSZ3A[6:0] RSZ		

- Busy-writable registers

These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantaneously. Registers that are not shadowed are busy-writable.

Only for busy-writable registers, the ideal procedure for changing the IPIPEIF registers is IF (PCR.BUSY == 0) OR IF (EOF interrupt occurs):

- Disable IPIPEIF ([IPIPEIF\\_ENABLE\[0\]](#) ENABLE = 0x0).
- Change registers.
- Enable IPIPEIF ([IPIPEIF\\_ENABLE\[0\]](#) ENABLE = 0x1).

#### 8.3.4.3.4 ISS ISP IPIPEIF Interframe Operations

Between frames, it may be necessary to enable or disable functions or to modify the memory pointers. Because several of the registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The host controller can perform these changes upon receiving an interrupt.

When reading input data from the BL, the host must check [IPIPEIF\\_DTUF](#) or the [ISP5\\_IRQSTATUS\\_RAW2\\_i\[1\]](#) [IPIPEIF\\_UDF](#) register (if this event is enabled and mapped to the ISP IRQ lines) during vertical blanking to see if an underflow occurred.

If an underflow occurs it means the system is congested because too much bandwidth is being generated. It is most likely that the scenario being passed is too memory bandwidth-intensive. If the bit is set, software must clear the bit. If the process is taking place from memory-to-memory, the software may try to re-initiate the data flow. Software must decide the sequence to execute after an underflow.

#### 8.3.4.3.5 ISS ISP IPIPEIF Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the IPIPEIF module. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If BL is the source for the IPIPEIF:
  - The memory output line offset and address must be on 32-byte boundaries.
  - In DFS block, [IPIPEIF\\_LPFR](#) must be > 0, because the first line cannot be fetched.
  - [IPIPEIF\\_PPLN](#) > [IPIPEIF\\_HNUM](#)
  - [IPIPEIF\\_LPFR](#) > [IPIPEIF\\_VNUM](#) + 1
- There are restrictions on [IPIPEIF\\_CFG1\[15:14\]](#) INPSRC1 and [IPIPEIF\\_CFG1\[3:2\]](#) INPSRC2 combinations. See [Table 8-314](#) for details.

#### 8.3.4.4 ISS ISP IPIPE Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the ISS PIPE module.

##### 8.3.4.4.1 Global Initialization

###### 8.3.4.4.1.1 Surrounding Modules Global Initialization

This initialization of surrounding modules is based on the integration of the ISS ISP.

###### 8.3.4.4.1.2 ISS IPIPE Global Initialization

###### 8.3.4.4.1.2.1 Main Sequence – ISS ISP IPIPE Global Initialization

This procedure initializes the ISS ISP PIPE modules after a POR or software reset.

**Table 8-360. ISS Global Initialization**

Step	Register/Bit Field/Programming Model	Value
Set the IPIPE processing modes.	IPIPE_SRC_MODE[0] OST	0x-
Select the IPIPEIF module as a source.	IPIPE_SRC_MODE[1] WRT	0x1
Set the vertical start position of the window to process.	IPIPE_SRC_VPS[15:0] VAL	0x-
Set the horizontal start position of the window to process.	IPIPE_SRC_HPS[15:0] VAL	0x-
Set the vertical size of the processing area.	IPIPE_SRC_VSZ[12:0] VAL	0X-
Set the horizontal size of the processing area.	IPIPE_SRC_HSZ[12:1] VAL	0x-
Enable clk_arm_g0.	IPIPE_GCK_MMR[0] REG	0x-
Enable the clk_pix_g3.	IPIPE_GCK_PIX[3] G3	0x-
Enable the clk_pix_g2.	IPIPE_GCK_PIX[2] G2	0x-
Enable the clk_pix_g1.	IPIPE_GCK_PIX[1] G1	0x-
Enable the clk_pix_g0.	IPIPE_GCK_PIX[0] G0	0x-
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

### 8.3.4.4.1.2.2 Subsequence – ISS ISP IPIPE Defect Pixel Correction Initialization

#### 8.3.4.4.1.2.2.1 Subsequence – ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

**Table 8-361. ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)**

Step	Register/Bit Field/Programming Model	Value
Set the address of the first valid data in the LUT.	IPIPE_DPC_LUT_ADR[9:0] ADR	0x-
Set the LUT type.	IPIPE_DPC_LUT_SEL[1] TBL	0x-
Set the size of the LUT.	IPIPE_DPC_LUT_SIZ[9:0] SIZ	0x-
Set the dot replacement correction method .	IPIPE_DPC_LUT_SEL[0] DOT	0x-
Enable LUT DPC.	IPIPE_DPC_LUT_EN[0] EN	0x1

### 8.3.4.4.1.2.3 Subsequence – ISS ISP IPIPE White Balance Initialization

**Table 8-362. ISS ISP IPIPE White Balance Initialization**

Step	Register/Bit Field/Programming Model	Value
Set the offset before white balance.	IPIPE_WB2_OFT_R[11:0] VAL IPIPE_WB2_OFT_GR[11:0] VAL IPIPE_WB2_OFT_GB[11:0] VAL IPIPE_WB2_OFT_B[11:0] VAL	0x-
Set the white balance gain.	IPIPE_WB2_WGN_R[12:0] VAL IPIPE_WB2_WGN_GR[12:0] VAL IPIPE_WB2_WGN_GB[12:0] VAL IPIPE_WB2_WGN_B[12:0] VAL	0x-

### 8.3.4.4.1.2.4 Subsequence – ISS ISP IPIPE RGB2RGB Blending Module Initialization

**Table 8-363. ISS ISP IPIPE RGB2RGB Blending Module Initialization**

Step	Register/Bit Field/Programming Model	Value
Set gain range.	IPIPE_RGB1_MUL_RR[11:0] VAL IPIPE_RGB1_MUL_GR[11:0] VAL IPIPE_RGB1_MUL_BR[11:0] VAL IPIPE_RGB1_MUL_RG[11:0] VAL IPIPE_RGB1_MUL_GG[11:0] VAL IPIPE_RGB1_MUL_BG[11:0] VAL IPIPE_RGB1_MUL_RB[11:0] VAL IPIPE_RGB1_MUL_GB[11:0] VAL IPIPE_RGB1_MUL_BB[11:0] VAL	0x-
Se the offset range for each component.	IPIPE_RGB1_OFT_OR[12:0] VAL IPIPE_RGB1_OFT_OG[12:0] VAL IPIPE_RGB1_OFT_OB[12:0] VAL	0x-

#### 8.3.4.4.1.2.5 Subsequence – ISS ISP IPIPE Gamma Correction Module Initialization

**Table 8-364. ISS ISP IPIPE Gamma Correction Module Initialization**

Step	Register/Bit Field/Programming Model	Value
Select the gamma table.	IPIPE_GMM_CFG[4] TBL	0x-
Set the size of the gamma table.	IPIPE_GMM_CFG[6:5]SIZ	0x-
(optional) Insert bypass bit for each color.	IPIPE_GMM_CFG[0] BYPR IPIPE_GMM_CFG[1] BYPG IPIPE_GMM_CFG[2] BYPB	0x1

#### 8.3.4.4.1.2.6 Subsequence – ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix Initialization

**Table 8-365. ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix Initialization**

Step	Register/Bit Field/Programming Model	Value
Set the gain range.	IPIPE_RGB2_MUL_RR[10:0] VAL IPIPE_RGB2_MUL_GR[10:0] VAL IPIPE_RGB2_MUL_BR[10:0] VAL IPIPE_RGB2_MUL_RG[10:0] VAL IPIPE_RGB2_MUL_GG[10:0] VAL IPIPE_RGB2_MUL_BG[10:0] VAL IPIPE_RGB2_MUL_RB[10:0] VAL IPIPE_RGB2_MUL_GB[10:0] VAL IPIPE_RGB2_MUL_BB[10:0] VAL	0x-
Set the offset.	IPIPE_RGB2_OFT_OR[10:0] VAL IPIPE_RGB2_OFT_OG[10:0] VAL IPIPE_RGB2_OFT_OB[10:0] VAL	0x-

#### 8.3.4.4.1.2.7 Subsequence – ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization

**Table 8-366. ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization**

Step	Register/Bit Field/Programming Model	Value
Set the brightness control.	IPIPE_YUV_ADJ[15:8] BRT	0x-
Set the contrast control.	IPIPE_YUV_ADJ[7:0] CRT	0x-
Configure the gain range.	IPIPE_YUV_MUL_RY[11:0]VAL IPIPE_YUV_MUL_GY[11:0]VAL IPIPE_YUV_MUL_BY[11:0]VAL IPIPE_YUV_MUL_RCB[11:0]VAL IPIPE_YUV_MUL_GCB[11:0]VAL IPIPE_YUV_MUL_BCB[11:0]VAL IPIPE_YUV_MUL_RCR[11:0]VAL IPIPE_YUV_MUL_GCR[11:0]VAL IPIPE_YUV_MUL_BCR[11:0]VAL	0x-

**Table 8-366. ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the output offset value for Y.	IPIPE_YUV_OFT_Y[10:0] VAL	0x-
Set the output offset value for Cr.	IPIPE_YUV_OFT_CR[10:0] VAL	0x-
Set the output offset value for Cb.	IPIPE_YUV_OFT_CB[10:0] VAL	0x-

#### 8.3.4.4.1.2.8 Subsequence – ISS ISP IPIPE 4:2:2 Conversion Module Initialization

**Table 8-367. ISS ISP IPIPE 4:2:2 Conversion Module Initialization**

Step	Register/Bit Field/Programming Model	Value
If: RAW BAYER data set as an input?	IPIPE_SRC_FMT.[1:0] FMT	= 0x0
Select the Y and Cb/Cr sampling point.	IPIPE_YUV_PHS[0] POS	0x-
Enable 4:2:2 conversion module.	IPIPE_YUV_PHS[1] PLF	0x-
<b>ELSE</b>		

#### 8.3.4.4.1.2.9 Subsequence – ISS ISP IPIPE 2D Edge Enhancer Initialization

**Table 8-368. ISS ISP IPIPE 2D Edge Enhancer Initialization**

Step	Register/Bit Field/Programming Model	Value
Set the merging method.	IPIPE_YEE_TYP[0] SEL	0x-
Set the downshift length of HPF in the edge enhancer.	IPIPE_YEE_SHF[3:0] SHF	0x-
Set the edge enhancer lower threshold before referring to the LUT.	IPIPE_YEE_THR[5:0] VAL	0x-
Set the multiplier coefficient in the HPF.	IPIPE_YEE_MUL_00[9:0] VAL IPIPE_YEE_MUL_01[9:0] VAL IPIPE_YEE_MUL_02[9:0] VAL IPIPE_YEE_MUL_10[9:0] VAL IPIPE_YEE_MUL_11[9:0] VAL IPIPE_YEE_MUL_12[9:0] VAL IPIPE_YEE_MUL_20[9:0] VAL IPIPE_YEE_MUL_21[9:0] VAL IPIPE_YEE_MUL_22[9:0] VAL	0x-
Set the edge sharpener HPF value lower limit.	IPIPE_YEE_E_THR_1[11:0] VAL	0x-
Set the edge sharpener HPF value upper limit.	IPIPE_YEE_E_THR_2[5:0] VAL	0x-
Set the edge sharpener gain value on gradient.	IPIPE_YEE_G_GAN[7:0] VAL	0x-
Set the edge sharpener gain value.	IPIPE_YEE_E_GAN[7:0] VAL	0x-
Set the edge sharpener offset value on gradient.	IPIPE_YEE_G_OFT[5:0] VAL	0x-
Enable the 2D edge enhancer.	IPIPE_YEE_EN[0] EN	0x1

#### 8.3.4.4.1.2.10 Subsequence – ISS ISP IPIPE Histogram Initialization

**Table 8-369. ISS ISP IPIPE Histogram Initialization**

Step	Register/Bit Field/Programming Model	Value
Select input source.	IPIPE_HST_SEL[2] SEL	0x-
Select the Bayer mode.	IPIPE_HST_SEL[1:0] TYP	0x-
Set the number of bins.	IPIPE_HST_PARA[13:12] BIN	0x-
Enable region(area) 0.	IPIPE_HST_PARA[0] RGN0	0x-
Enable region(area) 1.	IPIPE_HST_PARA[1] RGN1	0x-
Enable region(area) 2.	IPIPE_HST_PARA[2] RGN2	0x-

**Table 8-369. ISS ISP IPIPE Histogram Initialization (continued)**

Step	Register/Bit Field/Programming Model	Value
Enable region(area) 3.	IPIPE_HST_PARA[3] RGN3	0x-
Set the vertical position of region 0.	IPIPE_HST_0_VPS[12:1] VAL	0x-
Set the vertical position of region 1.	IPIPE_HST_1_VPS[12:1] VAL	0x-
Set the vertical position of region 2.	IPIPE_HST_2_VPS[12:1] VAL	0x-
Set the vertical position of region 3.	IPIPE_HST_3_VPS[12:1] VAL	0x-
Set the horizontal position of region 0.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the horizontal position of region 1.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the horizontal position of region 2.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the horizontal position of region 3.	IPIPE_HST_0_HPS[12:1] VAL	0x-
Set the vertical size of region 0.	IPIPE_HST_0_VSZ[12:1] VAL	0x-
Set the vertical size of region 1.	IPIPE_HST_1_VSZ[12:1] VAL	0x-
Set the vertical size of region 2.	IPIPE_HST_2_VSZ[12:1] VAL	0x-
Set the vertical size of region 3.	IPIPE_HST_3_VSZ[12:1] VAL	0x-
Set the horizontal size of region 0.	IPIPE_HST_0_HSZ[12:1] VAL	0x-
Set the horizontal size of region 1.	IPIPE_HST_1_HSZ[12:1] VAL	0x-
Set the horizontal size of region 2.	IPIPE_HST_2_HSZ[12:1] VAL	0x-
Set the horizontal size of region 3.	IPIPE_HST_3_HSZ[12:1] VAL	0x-
Enable selection of the color pattern 0 (R).	IPIPE_HST_PARA[4] COL0	0x-
Enable selection of the color pattern 1 (G).	IPIPE_HST_PARA[5] COL1	0x-
Enable selection of the color pattern 2 (B).	IPIPE_HST_PARA[6] COL2	0x-
Enable selection of the color pattern 3 (Y).	IPIPE_HST_PARA[7] COL3	0x-
Set the shift length of the input data.	IPIPE_HST_PARA[11:8] SHF	0x-
Enable/disable histogram memory clear.	IPIPE_HST_TBL[1] CLR	0x-
Select table for store the histogram data.	IPIPE_HST_TBL[1] CLR	0x-
<b>IF:</b> Is input from noise filter?	IPIPE_HST_SEL[2] SEI	0x0
Gain for color for R.	IPIPE_HST_MUL_R[7:0]GAIN	0x-
Gain for color for GR.	IPIPE_HST_MUL_GR[7:0]GAIN	0x-
Gain for color for GB.	IPIPE_HST_MUL_GB[7:0]GAIN	0x-
Gain for color for B.	IPIPE_HST_MUL_B[7:0]GAIN	0x-
<b>ENDIF</b>		
Select processing mode.	IPIPE_HST_MODE[0]OST	0x-
Enable histogram.	IPIPE_HST_EN[0] EN	0x1

### 8.3.4.4.1.2.11 Subsequence – ISS ISP IPIPE Boxcar Initialization

**Table 8-370. ISS ISP IPIPE Boxcar Initialization**

Step	Register/Bit Field/Programming Model	Value
Select the processing mode.	IPIPE_BOX_MODE[0] OST	0x-
Set the size of blocks.	IPIPE_BOX_TYP[0] SEL	0x-
Set the higher 16 bits of the first address of output in memory.	IPIPE_BOX_SDR_SAD_H[15:0] VAL	0x-
Set the lower 16 bits of the first address of output in memory.	IPIPE_BOX_SDR_SAD_L[15:5] VAL	0x-
Set the downshift value.	IPIPE_BOX_SHF[2:0] VAL	0x-
Enable boxcar.	IPIPE_BOX_EN[0] EN	0x1

### 8.3.4.4.2 ISS ISP IPIPE Operational Modes Configuration

#### 8.3.4.4.2.1 ISS ISP IPIPE Processing Path: Case 1 Configuration

**Table 8-371. ISS ISP IPIPE Processing Path: Case 1 Configuration**

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 1	IPIPE_SRC_FMT[1:0] FMT	0x0
Configure IPIPE DPC.	See <a href="#">Section 8.3.4.4.1.2.2, Subsequence – ISS ISP IPIPE Defect Pixel Correction Initialization.</a>	
Configure IPIPE white balance.	See <a href="#">Section 8.3.4.4.1.2.3, Subsequence – ISS ISP IPIPE White Balance Initialization.</a>	
Configure IPIPE RGB2RGB blending module.	See <a href="#">Section 8.3.4.4.1.2.4, Subsequence – ISS ISP IPIPE RGB2RGB Blending Module Initialization.</a>	
Configure IPIPE gamma correction module.	See <a href="#">Section 8.3.4.4.1.2.5, Subsequence – ISS ISP IPIPE Gamma Correction Module Initialization.</a>	
Configure IPIPE 2nd RGB2RGB conversion matrix.	See <a href="#">Section 8.3.4.4.1.2.6, Subsequence – ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix Initialization.</a>	
Configure IPIPE RGB2YCbCr conversion matrix.	See <a href="#">Section 8.3.4.4.1.2.7, Subsequence – ISS ISP IPIPE RGB2YCbCr Conversion Matrix Initialization.</a>	
Configure IPIPE 2D edge enhancer.	See <a href="#">Section 8.3.4.4.1.2.9, Subsequence – ISS ISP IPIPE 2D Edge Enhancer Initialization.</a>	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

#### 8.3.4.4.2.2 ISS ISP IPIPE Processing Path: Case 2 Configuration

**Table 8-372. ISS ISP IPIPE Processing Path: Case 2 Configuration**

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 2.	IPIPE_SRC_FMT[1:0] FMT	0x1
Configure IPIPE DPC.	See <a href="#">Section 8.3.4.4.1.2.2, Subsequence – ISS ISP IPIPE Defect Pixel Correction Initialization.</a>	
Configure IPIPE white balance.	See <a href="#">Section 8.3.4.4.1.2.3, Subsequence – ISS ISP IPIPE White Balance Initialization.</a>	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

#### 8.3.4.4.2.3 ISS ISP IPIPE Processing Path: Case 3 Configuration

**Table 8-373. ISS ISP IPIPE Processing Path: Case 3 Configuration**

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 3.	IPIPE_SRC_FMT[1:0] FMT	0x3
Configure IPIPE 2D edge enhancer.	See <a href="#">Section 8.3.4.4.1.2.9, Subsequence - ISS ISP IPIPE 2D Edge Enhancer Initialization.</a>	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

#### 8.3.4.4.2.4 ISS ISP IPIPE Processing Path: Case 4 Configuration

**Table 8-374. ISS ISP IPIPE Processing Path: Case 4 Configuration**

Step	Register/Bit Field/Programming Model	Value
Select processing path: Case 4.	IPIPE_SRC_FMT[1:0] FMT	0x2
Configure IPIPE boxcar.	See <a href="#">Section 8.3.4.4.1.2.11, Subsequence – ISS ISP IPIPE Boxcar Initialization.</a>	

**Table 8-374. ISS ISP IPIPE Processing Path: Case 4 Configuration (continued)**

Step	Register/Bit Field/Programming Model	Value
Configure IPIEE histogram.	See <a href="#">Section 8.3.4.4.1.2.10, Subsequence – ISS ISP IPIPE Histogram Initialization.</a>	
Enable IPIPE module.	IPIPE_SRC_EN[0] EN	0x1

### 8.3.4.5 ISS ISP RSZ Programming Model

This section discusses programming configuration steps related to software control of the RSZ. It lists the registers that must be programmed in different modes, describes how to enable and disable the RSZ and how to check the status of the image resizing procedure, and discusses the different register access types and several programming constraints.

#### 8.3.4.5.1 ISS ISP RSZ Hardware Setup/Initialization

This section discusses the configuration of the RSZ required before image processing can begin.

##### 8.3.4.5.1.1 ISS ISP RSZ Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the RSZ module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the RSZ. For more information, see [Section 8.3.3.5.4, ISS ISP RSZ Integration..](#)

**Table 8-375. ISS ISP RSZ Surrounding Modules Global Initialization**

Surrounding Modules	Comments
PRCM	Module interface and functional clocks must be enabled. RSZ is part of ISP, which is part of ISS. To enable the clocks for ISS, see <a href="#">Chapter 3, Power, Reset, and Clock Management</a> . Also see <a href="#">Section 8.3.2.1.1, ISS ISP Clocks</a> .
(optional) MPU INTC	The MPU INTC must be configured to enable interrupts from the RSZ. For information about how to configure the local ISS interrupt channels, see <a href="#">Section 8.3.2.2, ISS ISP Interrupt Tree</a> , and <a href="#">Section 8.1.2.1.1, ISS Interrupt Merger</a> . Then, to configure the outside ISS boundary channels, see <a href="#">Chapter 17, Interrupt Controllers</a> .
(optional) IPIPE	Configure the IPIPE module to process and pass data to the RSZ module. See <a href="#">Section 8.3.4.4, ISS ISP IPIPE Programming Model</a> .
(optional) IPIPEIF	Configure the IPIPEIF module to process and pass data to the RSZ module. See <a href="#">Section 8.3.4.3, ISS ISP IPIPEIF Programming Model</a> .
(optional) BL	Configure the BL for reading back data from memory. See <a href="#">Section 8.3.4.7, ISS ISP BL Programming Model</a> .
(optional) CSI2	If the data comes from the sensor, configure the CSI2-A interface. See <a href="#">Section 8.2.5.4, ISS CSI2 Programming Model</a> .
(optional) CCP2	If the data comes from the sensor, configure the CCP2 interface. See <a href="#">Section 8.2.4.4, ISS CCP2 Programming Model</a> .

**NOTE:** The MPU INTC configurations are necessary if the interrupt-based communication modes are used. The IPIPE or IPIPEIF configuration is also necessary for putting data into the RSZ. Moreover, if data comes from memory, the BL must be configured. If data comes from the image sensor CSI2 or CCP2, the interface must be configured.

### 8.3.4.5.1.2 ISS ISP RSZ Initial Register Setup

Before enabling the RSZ, the hardware must be properly configured through register writes. [Table 8-376](#) identifies the sequence to be used before enabling the hardware.

**Table 8-376. ISS ISP RSZ Initial Register Setup**

Step	Register/Bit Field/Programming Model	Value
Set the MMR clock to enable RSZ register read/write access.	<a href="#">RSZ_GCK_MMR</a> [0] MMR	0x1
Determine whether or not a bypass mode will be used and set the RSZ core functional clock accordingly.	<a href="#">RSZ_GCK_SDR</a> [0] CORE	0x-
<b>IF: Is the core clock enabled?</b>	<a href="#">RSZ_GCK_SDR</a> [0] CORE	= 0x1
Enable RSZ engine clocks.	<a href="#">RSZ_SYSCONFIG</a> [8] RSZA_CLK_EN <a href="#">RSZ_SYSCONFIG</a> [9] RSZB_CLK_EN	0x1
<b>ELSE: The input data buffer is not used?</b>	<a href="#">RSZ_GCK_SDR</a> [0] CORE	= 0x0
Set the bypass mode accordingly.	<a href="#">RSZ_SRC_FMT0</a> [1] BYPASS	0x-
<b>ENDIF</b>		
Enable the RSZ core clock.	<a href="#">RSZ_GCK_SDR</a> [0] CORE	0x1
Determine the upscale ratio and functional clock, and adjust the fractional clock divider as appropriate.	<a href="#">RSZ_FRACDIV</a> [15:0] <a href="#">RSZ_FRACDIV</a>	0x-
Set the low threshold of the RSZ input data buffer as appropriate.	<a href="#">RSZ_IN_FIFO_CTRL</a> [28:16] THRLD_LOW	0x-
Set the high threshold of the RSZ input data buffer as appropriate.	<a href="#">RSZ_IN_FIFO_CTRL</a> [12:0] THRLD_HIGH	0x-
Determine whether IPIPE or IPEPIF will be the source of input and set this bit accordingly.	<a href="#">RSZ_SRC_FMT0</a> [0] SEL	0x-
Determine whether the RSZ will process as long as data is present in the input buffer, or whether it will wait for a WEN signal from the input source (IPIPE or IPIPEIF) to process lines arrived only during WEN high state.	<a href="#">RSZ_SRC_MODE</a> [1] WRT	0x-
Select the processing mode (one shot or free running). This bit controls the RSZ module. There are also additional mode settings for the two RSZ engines within. After RSZ reset, the mode is automatically set to free running.	<a href="#">RSZ_SRC_MODE</a> [0] OST	0x-
Configure the number of interrupt intervals for writing lines into CBUFF for the two RSZ engines.	<a href="#">RSZ_IRQ_RZA</a> [12:0] RZA <a href="#">RSZ_IRQ_RZB</a> [12:0] RZB	0x-
Enable the RSZ module.	<a href="#">RSZ_SRC_EN</a> [0] EN	0x1
Enable the RSZ engine A.	<a href="#">RZA_EN</a> [0] EN	0x1
Enable the RSZ engine B.	<a href="#">RZB_EN</a> [0] EN	0x1

**NOTE:** RSZ engine A or RSZ engine B must be enabled after setting all needed configuration parameters.

### 8.3.4.5.1.3 ISS ISP RSZ Reset Behavior

Because the RSZ module has no software reset, software can issue one at the ISP level. Moreover, upon hardware reset, all the registers in the RSZ are reset to their reset values. [Table 8-377](#) identifies the proper software sequence before and after RSZ reset issues at the ISP level.

**Table 8-377. ISS ISP RSZ Reset Behavior**

Step	Register/Bit Field/Programming Model	Value
<b>ELSE IF: Is FIFO overflow or blanking error present?</b>	ISP5_IRQSTATUS_[18] RSZ_FIFO_IN_OVF or ISP5_IRQSTATUS_[19] RSZ_FIFO_IN_BLK_ERR	= 0x1
Clear the FIFO blanking event.	ISP5_IRQENABLE_CLR_[19] RSZ_FIFO_IN_BLK_ERR	0x1
Clear the overflow event.	SP5_IRQENABLE_CLR_[18] RSZ_FIFO_IN_OVF	0x1
<b>ELSE: No FIFO overflow or blanking error is present?</b>		
Wait until there is no DMA process and the module ready for reset.	ISP5_SYSCONFIG[1] SOFTRESET and ISP5_IRQSTATUS_[15] RSZ_INT_DMA	= 0x0
<b>ENDIF</b>		
Disable the source data.	RSZ_SRC_EN[0] EN	0x0
Reset the RSZ at the ISP level.	ISP5_SYSCONFIG[1] SOFTRESET	0x1
Check whether the RSZ has been reset properly.	ISP5_SYSCONFIG[1] SOFTRESET	0x-

#### 8.3.4.5.2 ISS ISP RSZ Global Image Processing Settings

This section discusses the configuration of the RSZ global settings before/during image frame processing. [Table 8-378](#) identifies the global RSZ functional sequence, which includes global control, frame settings, bandwidth control, and reversal output image frames.

**Table 8-378. ISS ISP RSZ Global Image Processing Settings**

Step	Register/Bit Field/Programming Model	Value
Initialize the RSZ module.	See <a href="#">Section 8.3.4.5.1</a> .	
Determine input data type and configure the source parameters.	See <a href="#">Section 8.3.4.5.2.1</a> .	
Determine if vertical flip of the output image will be performed by the two RSZ engines and set accordingly.	RSZ_SEQ[1] VRVA  RSZ_SEQ[3] VRVB	0x-
Determine if horizontal flip of the output image will be performed by the two RSZ engines and set accordingly.	RSZ_SEQ[0] HRVA  RSZ_SEQ[2] HRVB	0x-
Set the baseline address of the RSZ output to CBUFF. Best performance can be achieved by assigning address on a 128-byte boundary.	RZA_SDR_Y_BAD_H[15:0] Y_BAD_H  RZA_SDR_Y_BAD_L[15:0] Y_BAD_L RZB_SDR_Y_BAD_H[15:0] Y_BAD_H RZB_SDR_Y_BAD_L[15:0] Y_BAD_L RZA_SDR_C_BAD_H[15:0] C_BAD_H RZA_SDR_C_BAD_L[15:0] C_BAD_L RZB_SDR_C_BAD_H[15:0] C_BAD_H RZB_SDR_C_BAD_L[15:0] C_BAD_L	0x-

**Table 8-378. ISS ISP RSZ Global Image Processing Settings (continued)**

Step	Register/Bit Field/Programming Model	Value
Set the start address of the RSZ output to CBUFF. The first data output will be written to this address. If the first line of a frame is written at the beginning of the CBUFF memory, then SAD = BAD and PTR_S = 0. It is strongly advised to set up this address on a 128-byte boundary, which will lead to the best performance.	RZA_SDR_Y_SAD_H[15:0] Y_SAD_H	0x-
	RZA_SDR_Y_SAD_L[15:0] Y_SAD_L	
	RZB_SDR_Y_SAD_H[15:0] Y_SAD_H	
	RZB_SDR_Y_SAD_L[15:0] Y_SAD_L	
	RZA_SDR_C_SAD_H[15:0] C_SAD_H	
	RZA_SDR_C_SAD_L [15:0] C_SAD_L	
	RZB_SDR_C_SAD_H[15:0] C_SAD_H	
	RZB_SDR_C_SAD_L[15:0] C_SAD_L	
Set the start pointer of the CBUFF internal counter. It must be set up as PTR_S = (SAD – BAD) / OFT. PTR_S is expressed in number of lines.	RZA_SDR_Y_PTR_S[12:0] Y_PTR_S	0x-
	RZB_SDR_Y_PTR_S[12:0] Y_PTR_S	
	RZA_SDR_C_PTR_S[12:0] C_PTR_S	
	RZB_SDR_C_PTR_S[12:0] C_PTR_S	
Set the end pointer of the CBUFF internal counter. PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines.	RZA_SDR_Y_PTR_E[12:0] Y_PTR_E	0x-
	RZB_SDR_Y_PTR_E[12:0] Y_PTR_E	
	RZA_SDR_C_PTR_E[12:0] C_PTR_E	
	RZB_SDR_C_PTR_E[12:0] C_PTR_E	
Set the line of offset expressed in bytes between two lines in the CBUFF (Line 0 = SAD, Line 1 = SAD + 1 x OFT, Line 2 = SAD + 2 x OFT). PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines. Note: OFT does not necessarily correspond to the size of a line in a frame; it can be much bigger. The line offset must be a multiple of 128 bytes.	RZA_SDR_Y_OFT[16:0] Y_OFT	0x-
	RZB_SDR_Y_OFT[16:0] Y_OFT	
	RZA_SDR_C_OFT[16:0] C_OFT	
	RZB_SDR_C_OFT[16:0] C_OFT	
Determine output data type, whether it will be flipped, and configure the output memory addresses.	See <a href="#">Section 8.3.4.5.2.2</a> .	

**NOTE:** When data output is 4:2:2 or 4:2:0-Y only, the following values are not needed:

- RZx\_SDR\_C\_BAD\_x
- RZx\_SDR\_C\_SAD\_x
- RZx\_SDR\_C\_PTR\_S
- RZx\_SDR\_C\_PTR\_E
- RZx\_SDR\_C\_OFT

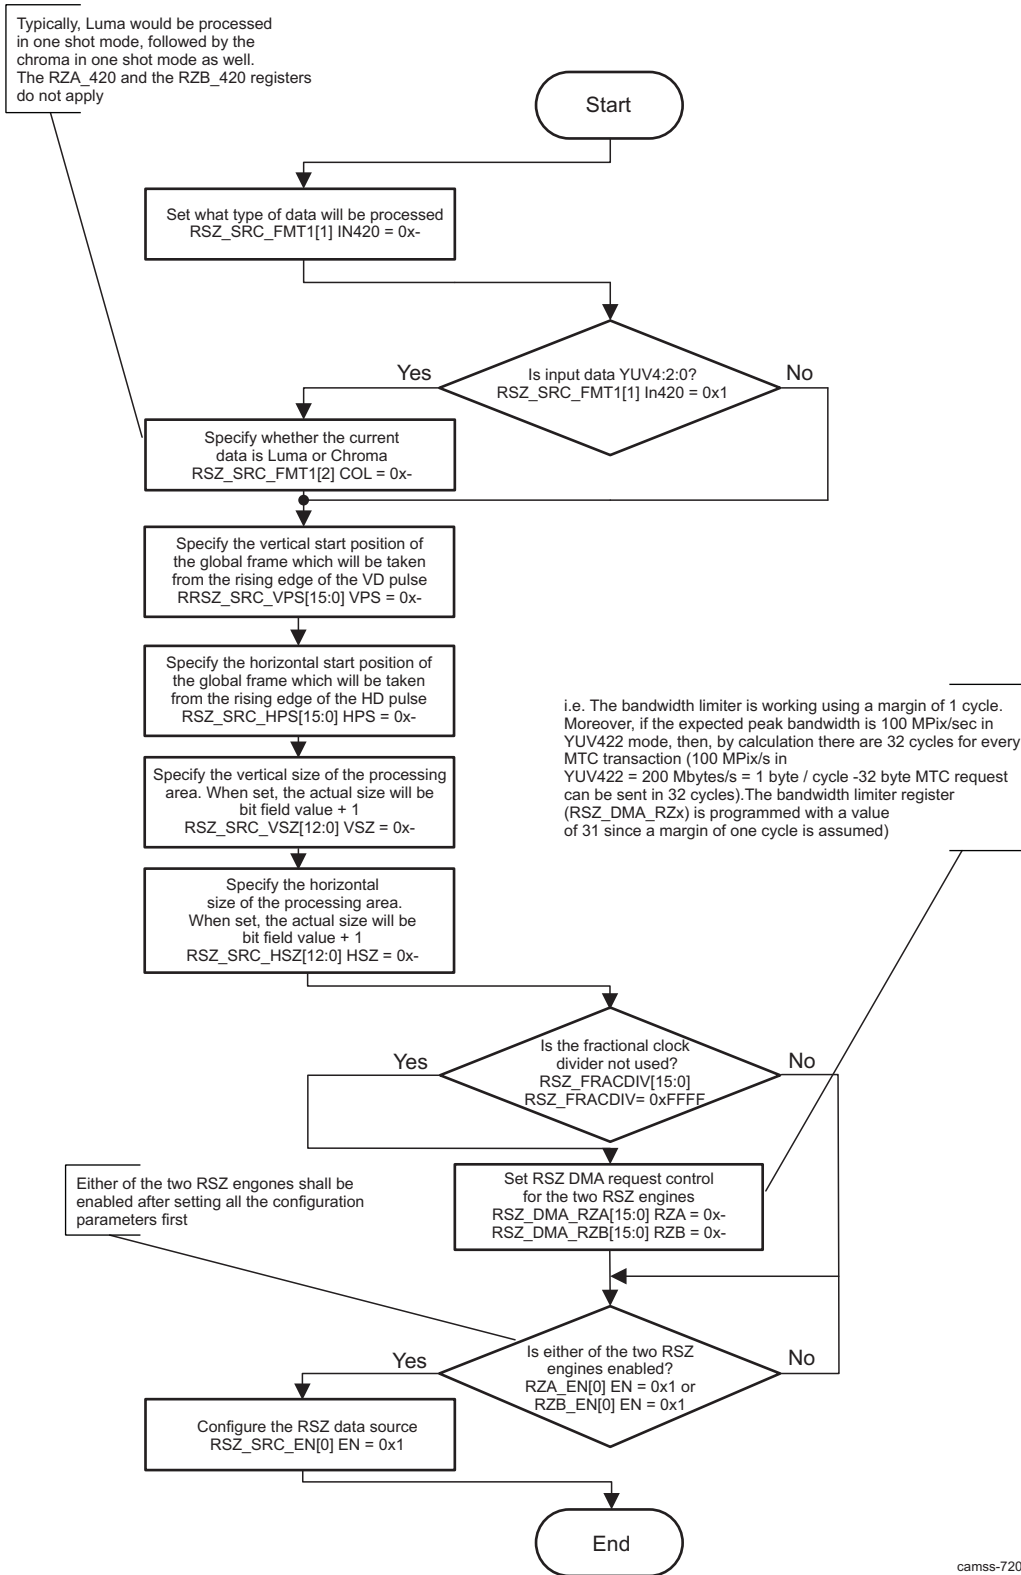

When output is 4:2:0-C only, the following values are not needed:

- RZx\_SDR\_Y\_BAD\_x
  - RZx\_SDR\_Y\_SAD\_x
  - RZx\_SDR\_Y\_PTR\_S
  - RZx\_SDR\_Y\_PTR\_E
  - RZx\_SDR\_Y\_OFT
- 

#### **8.3.4.5.2.1 ISS ISP RSZ Global Image Processing Settings – Subsequence 1**

The procedure shown in [Figure 8-239](#) determines which of the RSZ engines is enabled and the type of input data, and configures the source data parameters.

Figure 8-239. ISS ISP RSZ Global Image Processing Settings – Subsequence 1

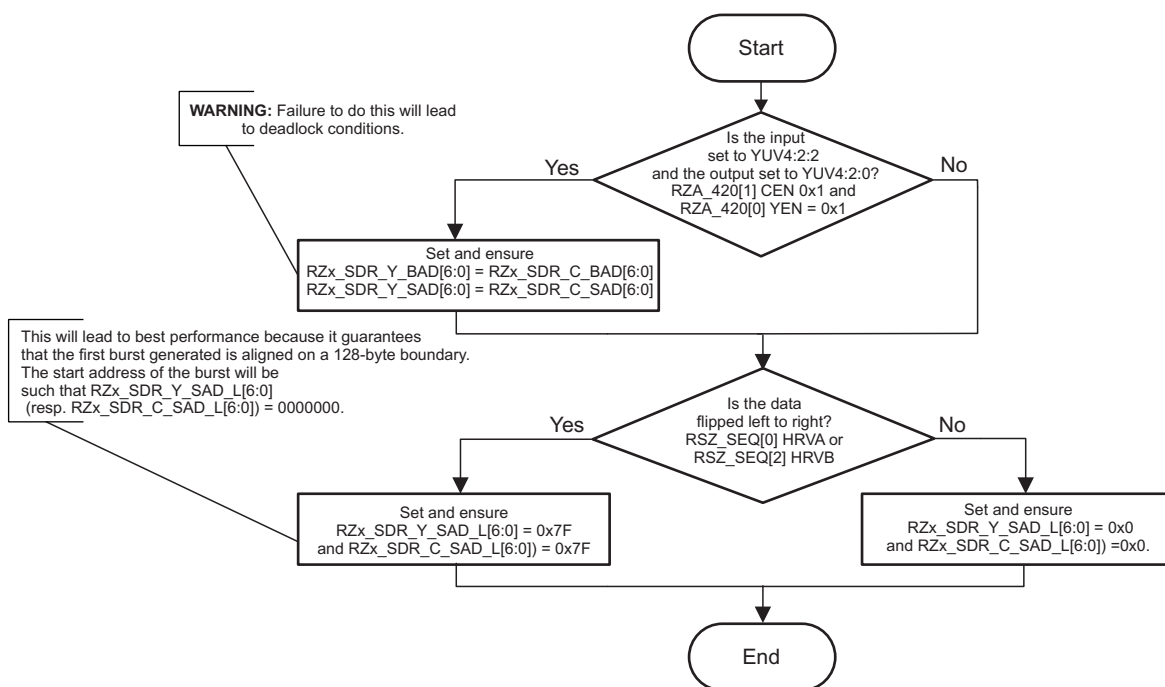

**Table 8-379. Register Call Summary for ISS ISP RSZ Global Image Processing Settings – Subsequence 1**

Register Name	Register Name	Register Name

### 8.3.4.5.3 ISS ISP RSZ Engines Interframe Image Processing Settings

This section discusses the configuration of the RSZ interframe image processing. [Table 8-381](#) identifies the setup sequence for the two different engines within the RSZ module.

**Table 8-381. ISS ISP RSZ Engines Interframe Image Processing Settings**

Step	Register/Bit Field/Programming Model	Value
<b>IF: Is the resizer module set to free-running mode?</b>	RSZ_SRC_MODE[0] OST	= 0x0
Set either of the engines to free-running mode to keep popping data out of the internal buffer. Otherwise, it will lead to an overflow event after the first frame.	RZA_MODE[0] MODE RZB_MODE[0] MODE	0x0
<b>ELSE: Is the resizer module set to one-shot mode?</b>		
Set both RSZ engines to one-shot mode.	RZA_MODE[0] MODE RZB_MODE[0] MODE	0x1
<b>ENDIF</b>
