## Turing Machines

Read K \& S 4.1.
Do Homework 17.

## Grammars, Recursively Enumerable Languages, and Turing Machines

Can we come up with a new kind of automaton that has two properties:

- powerful enough to describe all computable things unlike FSMs and PDAs
- simple enough that we can reason formally about it like FSMs and PDAs unlike real computers

## Turing Machines

At each step, the machine may:

- go to a new state, and

Finite State Control

- either
- write on the current square, or
$\mathrm{s}_{1}, \mathrm{~s}_{2}, \ldots \mathrm{~h}_{1}, \mathrm{~h}_{2}$
- move left or right

## A Formal Definition

A Turing machine is a quintuple $(\mathrm{K}, \Sigma, \delta, \mathrm{s}, \mathrm{H})$ :
K is a finite set of states;
$\Sigma$ is an alphabet, containing at least $\square$ and $\diamond$, but not $\rightarrow$ or $\leftarrow$;
$\mathrm{s} \in \mathrm{K}$ is the initial state;
$\mathrm{H} \subseteq \mathrm{K}$ is the set of halting states;
$\delta$ is a function from:
(K-H) $\quad \times \quad \Sigma$
to $\mathrm{K} \times$

$$
(\Sigma \cup\{\rightarrow, \leftarrow\})
$$

non-halting state $\times$ input symbol

$$
\text { state } \quad \times
$$

such that
(a) if the input symbol is $\diamond$, the action is $\rightarrow$, and
(b) $\diamond$ can never be written .

## Notes on the Definition

1. The input tape is infinite to the right (and full of $\square$ ), but has a wall to the left. Some definitions allow infinite tape in both directions, but it doesn't matter.
2. $\delta$ is a function, not a relation. So this is a definition for deterministic Turing machines.
3. $\delta$ must be defined for all state, input pairs unless the state is a halt state.
4. Turing machines do not necessarily halt (unlike FSM's). Why? To halt, they must enter a halt state. Otherwise they loop.
5. Turing machines generate output so they can actually compute functions.

## A Simple Example

A Turing Machine Odd Parity Machine:

## Formalizing the Operation

A configuration of a Turing machine $\mathrm{M}=(\mathrm{K}, \Sigma, \delta, \mathrm{s}, \mathrm{H})$ is a member of

| K | $\diamond \Sigma^{*} \times$ | $\left(\Sigma^{*}(\Sigma-\{\square\})\right) \cup \varepsilon$ |
| :---: | :--- | :--- | :--- |
| state | input up | input after |
| to scanned |  |  |
|  | square | scanned square |

The input after the scanned square may be empty, but it may not end with a blank. We assume the entire tape to the right of the input is filled with blanks.

$$
\begin{equation*}
(\mathrm{q}, \diamond \mathrm{aab}, \mathrm{~b}) \quad=\quad(\mathrm{q}, \diamond \mathrm{a}, \underline{b} b) \tag{1}
\end{equation*}
$$

$$
(\mathrm{h}, \diamond \square \mathrm{aabb}, \varepsilon) \quad=\quad(\mathrm{h}, \Delta \square \mathrm{aabb}) \quad \text { a halting configuration }
$$

## Yields

$\left.\left(\mathrm{q}_{1}, \mathrm{w}_{1} \underline{\mathrm{a}}_{1} \mathrm{u}_{1}\right)\right|_{\mathrm{M}}\left(\mathrm{q}_{2}, \mathrm{w}_{2} \mathrm{a}_{2} \underline{u}_{2}\right), \quad \mathrm{a}_{1}$ and $\mathrm{a}_{2} \in \Sigma, \quad$ iff $\quad \exists \mathrm{b} \in \Sigma \cup\{\leftarrow, \rightarrow\}, \delta\left(\mathrm{q}_{1}, \mathrm{a}_{1}\right)=\left(\mathrm{q}_{2}, \mathrm{~b}\right)$ and either:
(1) $b \in \Sigma, w_{1}=w_{2}, u_{1}=u_{2}$, and $a_{2}=b \quad$ (rewrite without moving the head)

$\Delta \square a a b b$

$\Delta \square a a \underline{a}$

Yields, Continued
(2) $\mathrm{b}=\leftarrow, \mathrm{w}_{1}=\mathrm{w}_{2} \mathrm{a}_{2}$, and either
(a) $u_{2}=a_{1} u_{1}$, if $a_{1} \neq \square$ or $u_{1} \neq \varepsilon$,

or
(b) $\mathrm{u}_{2}=\varepsilon$, if $\mathrm{a}_{1}=\square$ and $\mathrm{u}_{1}=\varepsilon$

If we scan left off the first square of the blank region, then drop that square from the configuration.
Yields, Continued
(3) $\mathrm{b}=\rightarrow, \mathrm{w}_{2}=\mathrm{w}_{1} \mathrm{a}_{1}$, and either
(a) $\mathrm{u}_{1}=\mathrm{a}_{2} \mathrm{u}_{2}$

$\diamond$ aaab
or
(b) $\mathrm{u}_{1}=\mathrm{u}_{2}=\varepsilon$ and $\mathrm{a}_{2}=\square$

If we scan right onto the first square of the blank region, then a new blank appears in the configuration.

## Yields, Continued

For any Turing machine M , let $\mid-\mathrm{m}^{*}$ be the reflexive, transitive closure of $\mid-\mathrm{m}$.
Configuration $\mathrm{C}_{1}$ yields configuration $\mathrm{C}_{2}$ if
$\mathrm{C}_{1} \mathrm{Fm}^{*} \mathrm{C}_{2}$.
A computation by $M$ is a sequence of configurations $C_{0}, C_{1}, \ldots, C_{n}$ for some $n \geq 0$ such that С $_{0} \mid$-м С $_{1} \mid$-м С $_{2} \mid$ м $\ldots \mid$ м С $_{\text {п }}$.

We say that the computation is of length $n$ or that it has $n$ steps, and we write

$$
\mathrm{C}_{0} \mid-{ }^{n} \mathrm{C}_{\mathrm{n}}
$$

## A Context-Free Example

M takes a tape of a's then b's, possibly with more a's, and adds b's as required to make the number of b's equal the number of a's.

$\mathrm{K}=\{0,1,2,3,4,5,6,7,8,9\}$
$\Sigma=\mathrm{a}, \mathrm{b}, \diamond, \square, 1,2$
$\mathrm{s}=0 \quad \mathrm{H}=\{9\} \quad \delta=$

An Example Computation

$\left.(0, \diamond$ ﹎aaab $)\right|_{-м}$
$\left.(1, \diamond \square$ aaab $)\right|_{-м}$
$\left.(2, \diamond \square \underline{1 a a b})\right|_{-м}$
$\left.(3, \diamond \square 1 \underline{a} a b)\right|_{-м}$
$(3, \diamond \square 1$ aab $) \mid-м$
$(3, \diamond \square 1 \mathrm{aab}) \mid-м$
$(4, \diamond \square 1$ аа 2$) \mid-м$

## Notes on Programming

The machine has a strong procedural feel.
It's very common to have state pairs, in which the first writes on the tape and the second move. Some definitions allow both actions at once, and those machines will have fewer states.

There are common idioms, like scan left until you find a blank.
Even a very simple machine is a nuisance to write.

## A Notation for Turing Machines

(1) Define some basic machines

- Symbol writing machines

For each $\mathrm{a} \in \Sigma-\{\diamond\}$, define $\mathrm{M}_{\mathrm{a}}$, written just $\mathrm{a},=(\{\mathrm{s}, \mathrm{h}\}, \Sigma, \delta, \mathrm{s},\{\mathrm{h}\})$, for each $b \in \Sigma-\{\diamond\}, \delta(s, b)=(h, a)$
$\delta(\mathrm{s}, \diamond)=(\mathrm{s}, \rightarrow)$
Example:
a writes an a

- Head moving machines

For each $\mathrm{a} \in\{\leftarrow, \rightarrow\}$, define $\mathrm{M}_{\mathrm{a}}$, written $\mathrm{R}(\rightarrow)$ and $\mathrm{L}(\leftarrow)$ :

```
for each b \in \Sigma -{ {},\delta(s,b) = (h, a)
            \delta(},\diamond)=(\textrm{s},->
Examples:
```

R moves one square to the right
aR writes an a and then moves one square to the right.

## A Notation for Turing Machines, Cont'd

(2) The rules for combining machines: as with FSMs

- Start in the start state of $\mathrm{M}_{1}$.
- Compute until $\mathrm{M}_{1}$ reaches a halt state.
- Examine the tape and take the appropriate transition.
- Start in the start state of the next machine, etc.
- Halt if any component reaches a halt state and has no place to go.
- If any component fails to halt, then the entire machine may fail to halt.

## Shorthands

## More Useful Machines

## An Example

Input: $\quad \Delta D w \quad w \in\{1\}^{*}$
Output: $\quad \Delta \underline{w^{3}}$

Input:
Output:
$\square \square w \square$

Example:

## Computing with Turing Machines

Read K \& S 4.2.
Do Homework 18.

## Turing Machines as Language Recognizers

Convention: We will write the input on the tape as:
$\Delta \square \mathrm{w} \square$, w contains no $\square_{\mathrm{s}}$
The initial configuration of $M$ will then be:
(s, $\left.\Delta \square_{\mathrm{w}} \mathrm{w}\right)$
A recognizing Turing machine $M$ must have two halting states: $y$ and $n$
Any configuration of M whose state is:
$y$ is an accepting configuration
n is a rejecting configuration
Let $\Sigma_{0}$, the input alphabet, be a subset of $\Sigma_{\mathrm{M}^{-}}\{\square, \diamond\}$
Then M decides a language $\mathrm{L} \subseteq \Sigma_{0} *$ iff for any string
$\mathrm{w} \in \Sigma_{0} *_{i t}$ is true that:
if $w \in L$ then $M$ accepts $w$, and
if $w \notin L$ then $M$ rejects $w$.
A language $L$ is recursive if there is a Turing machine $M$ that decides it.

## A Recognition Example

$\mathrm{L}=\left\{\mathrm{a}^{\mathrm{n}} \mathrm{b}^{\mathrm{n}} \mathrm{c}^{\mathrm{n}}: \mathrm{n} \geq 0\right\}$
Example: $\leqslant$ Daabbcc $\square \square \square \square \square \square \square \square$

Example: $\forall$ ㅡaaccb $\square \square \square \square \square \square \square$

## Another Recognition Example

$L=\left\{w c w: w \in\{a, b\}^{*}\right\}$

Example: $\vee$ ַabbcabb $\square \square$

Example: $\Delta$ ㄱacabb $\square \square$

## Do Turing Machines Stop?

FSMs

PDAs
Always halt after n steps, where n is the length of the input. At that point, they either accept or reject.

Turing machines Can do one of three things:
(1) Halt and accept
(2) Halt and reject
(3) Not halt

And now there is no algorithm to determine whether a given machine always halts.

## Computing Functions

Let $\Sigma_{0} \subseteq \Sigma-\{\Delta, \square\}$ and let $\mathrm{w} \in \Sigma_{0} *$
Convention: We will write the input on the tape as:
Qubl
The initial configuration of $M$ will then be:
$(\mathrm{s}, \stackrel{\square}{ } \mathrm{w})$
Define $\mathrm{M}(\mathrm{w})=\mathrm{y}$ iff:

- $\quad M$ halts if started in the input configuration,
- the tape of $M$ when it halts is $\forall \square y \square$, and
- $\mathrm{y} \in \Sigma_{0} *$

Let f be any function from $\Sigma_{0} *$ to $\Sigma_{0} *$.
We say that $M$ computes $f$ if, for all $w \in \Sigma_{0}{ }^{*}, M(w)=f(w)$
A function $f$ is recursive if there is a Turing machine $M$ that computes it.
$f(w)=w w$

Input: $\forall \square w \square \square \square \square \square \square$
Output: $\stackrel{\square}{\square} \mathrm{ww}$
Define the copy machine C:
$\Delta \underline{\square Q} \square \square \square \square \rightarrow$
$\diamond \square w \square w \square$

Remember the $\mathrm{S}_{\leftarrow}$ machine:

L
Then the machine to compute f is just $\quad>\mathrm{CS} \mathrm{L}_{\lrcorner} \leftarrow$

## Computing Numeric Functions

We say that a Turing machine $M$ computes a function $f$ from $N^{k}$ to $N$ provided that

$$
\operatorname{num}\left(\mathrm{M}\left(\mathrm{n}_{1} ; \mathrm{n}_{2} ; \ldots \mathrm{n}_{\mathrm{k}}\right)\right)=\mathrm{f}\left(\operatorname{num}\left(\mathrm{n}_{1}\right), \ldots \operatorname{num}\left(\mathrm{n}_{\mathrm{k}}\right)\right)
$$

Example: $\operatorname{Succ}(\mathrm{n})=\mathrm{n}+1$
We will represent $n$ in binary. So $n \in 0 \cup 1\{0,1\}^{*}$
Input: $\Delta \underline{D n} \square \square \square \square \square \square$
Output: $\Delta \square \mathrm{n}+1 \square$
Output: $\triangle \underline{\square} 10000 \square$

## Why Are We Working with Our Hands Tied Behind Our Backs?

Turing machines are more powerful than any of the other formalisms we have studied so far.
Turing machines are a lot harder to work with than all the real computers we have available.

Why bother?
The very simplicity that makes it hard to program Turing machines makes it possible to reason formally about what they can do. If we can, once, show that anything a real computer can do can be done (albeit clumsily) on a Turing machine, then we have a way to reason about what real computers can do.

## Recursively Enumerable and Recursive Languages

## Read K \& S 4.5.

## Recursively Enumerable Languages

Let $\Sigma_{0}$, the input alphabet to a Turing machine M , be a subset of $\Sigma_{\mathrm{M}}-\{\square, \diamond\}$
Let $\mathrm{L} \subseteq \Sigma_{0}{ }^{*}$.
M semidecides L iff
for any string $\mathrm{w} \in \Sigma_{0} *$,

| $\mathrm{w} \in \mathrm{L} \Rightarrow$ | M halts on input w |
| :---: | :---: |
| $\mathrm{w} \notin \mathrm{L} \Rightarrow$ | M does not halt on input w |
|  | $\mathrm{M}(\mathrm{w})=\uparrow$ |

$L$ is recursively enumerable iff there is a Turing machine that semidecides it.

## Examples of Recursively Enumerable Languages

$\mathrm{L}=\left\{\mathrm{w} \in\{\mathrm{a}, \mathrm{b}\}^{*}: \mathrm{w}\right.$ contains at least one a$\}$

$\mathrm{L}=\left\{\mathrm{w} \in\{\mathrm{a}, \mathrm{b},(,)\}^{*}: \mathrm{w}\right.$ contains at least one set of balanced parentheses $\}$

Recursively Enumerable Languages that Aren't Also Recursive

## A Real Life Example:

$\mathrm{L}=\{\mathrm{w} \in\{$ friends $\}: \mathrm{w}$ will answer the message you've just sent out $\}$

## Theoretical Examples

$\mathrm{L}=$ \{Turing machines that halt on a blank input tape \}
Theorems with valid proofs.

## Why Are They Called Recursively Enumerable Languages?

Enumerate means list.

We say that Turing machine $M$ enumerates the language $L$ iff, for some fixed state $q$ of $M$, $\mathrm{L}=\left\{\mathrm{w}:(\mathrm{s}, \Delta \underline{\square}) \mid-\mathrm{m}^{*}(\mathrm{q}, \Delta \square \mathrm{w})\right\}$

A language is Turing-enumerable iff there is a Turing machine that enumerates it.
Note that q is not a halting state. It merely signals that the current contents of the tape should be viewed as a member of L .

## Recursively Enumerable and Turing Enumerable

Theorem: A language is recursively enumerable iff it is Turing-enumerable.
Proof that Turing-enumerable implies RE: Let M be the Turing machine that enumerates L . We convert M to a machine M ' that semidecides L:

1. Save input w.
2. Begin enumerating $L$. Each time an element of $L$ is enumerated, compare it to $w$. If they match, accept.

The Other Way
Proof that RE implies Turing-enumerable:
If $\mathrm{L} \subseteq \Sigma^{*}$ is a recursively enumerable language, then there is a Turing machine M that semidecides L .
A procedure to enumerate all elements of L :
Enumerate all $w \in \Sigma^{*}$ lexicographically.

$$
\text { e.g., } \varepsilon, a, b, a a, a b, b a, b b, \ldots
$$

As each string $\mathrm{w}_{\mathrm{i}}$ is enumerated:

1. Start up a copy of $M$ with $w_{i}$ as its input.
2. Execute one step of each $\mathrm{M}_{\mathrm{i}}$ initiated so far, excluding only those that have previously halted.
3. Whenever an $\mathrm{M}_{\mathrm{i}}$ halts, output $\mathrm{w}_{\mathrm{i}}$.
$\varepsilon$ [1]
$\varepsilon[2] \quad$ a [1]
$\varepsilon[3] \quad$ a [2]
$\varepsilon$ [4]
a [3]
[1]
[政
a [4]
b [2]
b [3]
$\begin{array}{ll}\text { aa } & {[1]} \\ \text { aa } & {[2]} \\ \text { aa } & {[3]}\end{array}$
ab [1]
ab [2] ba [1]

## Every Recursive Language is Recursively Enumerable

If $L$ is recursive, then there is a Turing machine that decides it.
From M, we can build a new Turing machine $\mathrm{M}^{\prime}$ that semidecides L:

1. Let $n$ be the reject (and halt) state of $M$.
2. Then add to $\delta^{\prime}$
$((\mathrm{n}, \mathrm{a}),(\mathrm{n}, \mathrm{a}))$ for all $\mathrm{a} \in \Sigma$

What about the other way around?
Not true. There are recursively enumerable languages that are not recursive.

## The Recursive Languages Are Closed Under Complement

Proof: (by construction) If $L$ is recursive, then there is a Turing machine $M$ that decides $L$.
We construct a machine $M^{\prime}$ to decide $\bar{L}$ by taking $M$ and swapping the roles of the two halting states $y$ and $n$. M:

$\mathrm{M}^{\prime}$ :

This works because, by definition, M is

- deterministic
- complete

Are the Recursively Enumerable Languages Closed Under Complement?

M':

Lemma: There exists at least one language L that is recursively enumerable but not recursive.
Proof that M' doesn't exist: Suppose that the RE languages were closed under complement. Then if L is $\mathrm{RE}, \overline{\mathrm{L}}$ would be RE. If that were true, then $\bar{L}$ would also be recursive because we could construct $M$ to decide it:

1. Let $\mathrm{T}_{1}$ be the Turing machine that semidecides L .
2. Let $\mathrm{T}_{2}$ be the Turing machine that semidecides $\overline{\mathrm{L}}$.
3. Given a string $w$, fire up both $T_{1}$ and $T_{2}$ on $w$. Since any string in $\Sigma^{*}$ must be in either L or $\overline{\mathrm{L}}$, one of the two machines will eventually halt. If it's $T_{1}$, accept; if it's $T_{2}$, reject.
But we know that there is at least one RE language that is not recursive. Contradiction.

## Recursive and RE Languages

Theorem: A language is recursive iff both it and its complement are recursively enumerable.

## Proof:

- L recursive implies L and $\neg \mathrm{L}$ are RE: Clearly L is RE . And, since the recursive languages are closed under complement, $\neg \mathrm{L}$ is recursive and thus also RE .
- $\quad L$ and $\neg L$ are $R E$ implies $L$ recursive: Suppose $L$ is semidecided by $M 1$ and $\neg L$ is semidecided by M2. We construct $M$ to decide L by using two tapes and simultaneously executing M1 and M2. One (but not both) must eventually halt. If it's M1, we accept; if it's M2 we reject.

## Lexicographic Enumeration

We say that $M$ lexicographically enumerates $L$ if $M$ enumerates the elements of $L$ in lexicographic order. A language $L$ is lexicographically Turing-enumerable iff there is a Turing machine that lexicographically enumerates it.

Example: $L=\left\{a^{n} b^{n} c^{n}\right\}$
Lexicographic enumeration:

## Proof

Theorem: A language is recursive iff it is lexicographically Turing-enumerable.
Proof that recursive implies lexicographically Turing enumerable: Let M be a Turing machine that decides L. Then $\mathrm{M}^{\prime}$ lexicographically generates the strings in $\Sigma^{*}$ and tests each using M. It outputs those that are accepted by M. Thus M' lexicographically enumerates $L$.

## Proof, Continued

Proof that lexicographically Turing enumerable implies recursive: Let $M$ be a Turing machine that lexicographically enumerates $L$. Then, on input $w, M^{\prime}$ starts up $M$ and waits until either $M$ generates $w$ (so $M^{\prime}$ accepts), $M$ generates a string that comes after w (so $\mathrm{M}^{\prime}$ rejects), or M halts (so $\mathrm{M}^{\prime}$ rejects). Thus $\mathrm{M}^{\prime}$ decides L .

## Partially Recursive Functions

|  | Languages | Functions |
| :--- | :--- | :--- |
| Tm always halts | recursive | recursive |
| Tm halts if yes | recursively <br> enumerable | $?$ |

Suppose we have a function that is not defined for all elements of its domain.
Example: $\mathrm{f}: \mathrm{N} \rightarrow \mathrm{N}, \mathrm{f}(\mathrm{n})=\mathrm{n} / 2$
Partially Recursive Functions

One solution: Redefine the domain to be exactly those elements for which f is defined:

But what if we don't know? What if the domain is not a recursive set (but it is recursively enumerable)? Then we want to define the domain as some larger, recursive set and say that the function is partially recursive. There exists a Turing machine that halts if given an element of the domain but does not halt otherwise.
Semidecidable
Enumerable
Unrestricted grammar
Decision procedure
Lexicicographically enumerable
Complement is recursively enumer.

Closure

## Turing Machine Extensions

Read K \& S 4.3.1, 4.4.
Do Homework 19.

## Turing Machine Definitions

An alternative definition of a Turing machine:
(K, $\Sigma, \Gamma, \delta, \mathrm{s}, \mathrm{H})$ :
$\Gamma$ is a finite set of allowable tape symbols. One of these is $\square$
$\Sigma$ is a subset of $\Gamma$ not including $\square$, the input symbols.
$\delta$ is a function from:

$\mathrm{K} \times \Gamma \quad$ to $\underset{\substack{\mathrm{K}}}{\mathrm{K} \times}$| $(\Gamma-\{\square\}) \times\{\leftarrow, \rightarrow\}$ |
| ---: |
| state, |$\quad$| tape symbol, |
| ---: | :--- | L or R

Example transition: $((\mathrm{s}, \mathrm{a}),(\mathrm{s}, \mathrm{b}, \rightarrow))$

## Do these Differences Matter?

Remember the goal:

Define a device that is:

- powerful enough to describe all computable things,
- simple enough that we can reason formally about it

Both definitions are simple enough to work with, although details may make specific arguments easier or harder.
But, do they differ in their power?
Answer: No.
Consider the differences:

- One way or two way infinite tape: we're about to show that we can simulate two way infinite with ours.
- Rewrite and move at the same time: just affects (linearly) the number of moves it takes to solve a problem.

## Turing Machine Extensions

In fact, there are lots of extensions we can make to our basic Turing machine model. They may make it easier to write Turing machine programs, but none of them increase the power of the Turing machine because:

## We can show that every extended machine has an equivalent basic machine.

We can also place a bound on any change in the complexity of a solution when we from an extended machine to a basic machine.

Some possible extensions:

- Multiple tapes
- Two-way infinite tape
- Multiple read heads
- Two dimensional "sheet" instead of a tape
- Random access machine
- Nondeterministic machine

## Multiple Tapes

The transition function for a $k$-tape Turing machine:
((K-H)

$$
\begin{aligned}
& , \Sigma_{1} \\
& , \Sigma_{2} \\
& , \quad . \\
& , \quad . \\
& \left., \Sigma_{\mathrm{k}}\right)
\end{aligned}
$$

to

$$
\left(\mathrm{K}, \Sigma_{1^{\prime}} \cup\{\leftarrow, \rightarrow\}\right.
$$

$$
, \Sigma_{2^{\prime}} \cup\{\leftarrow, \rightarrow\}
$$

,
, .

$$
\left., \Sigma_{\mathrm{k}^{\prime}} \cup\{\leftarrow, \rightarrow\}\right)
$$

Input: input as before on tape 1 , others blank
Output: output as before on tape 1, others ignored
An Example of a Two Tape Machine
Copying a string

Another Two Tape Example - Addition

## Adding Tapes Adds No Power

Theorem: Let M be a k-tape Turing machine for some $\mathrm{k} \geq 1$. Then there is a standard Turing machine $\mathrm{M}^{\prime}$ where $\Sigma \subseteq \Sigma^{\prime}$, and such that:

- For any input string $x, M$ on input $x$ halts with output $y$ on the first tape iff $M^{\prime}$ on input $x$ halts at the same halting state and with the same output on its tape.
- If, on input $x, M$ halts after $t$ steps, then $M^{\prime}$ halts after a number of steps which is $O(t \cdot(|x|+t))$.

Proof: By construction

| $\diamond$ | $\checkmark$ | $\square$ | a | b | a | $\square$ | $\square$ | $\square$ | $\square$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 0 | 1 | 0 | 0 | 0 | 0 |  |  |
|  | $\checkmark$ | a | b | b | a | b | a |  |  |
|  | 0 | 1 | 0 | 0 | 0 | 0 | 0 |  |  |

Alphabet $\left(\Sigma^{\prime}\right)$ of $\mathrm{M}^{\prime}=\Sigma \cup(\Sigma \times\{0,1\})^{\mathrm{k}}$
e.g., $\diamond,(\diamond, 0, \diamond, 0),(\square, 0, a, 1)$

The Operation of $\mathrm{M}^{\prime}$

| $\diamond$ | $\bigcirc$ | $\square$ | a | b | a | $\square$ | $\square$ | $\square$ | $\square$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 0 | 1 | 0 | 0 | 0 | 0 |  |  |
|  | $\bigcirc$ | a | b | b | a | b | a |  |  |
|  | 0 | 1 | 0 | 0 | 0 | 0 | 0 |  |  |

1. Set up the multitrack tape:
1) Shift input one square to right, then set up each square appropriately.
2. Simulate the computation of $M$ until (if) $M$ would halt: (start each step to the right of the divided tape)
1) Scan left and store in the state the k-tuple of characters under the read heads. Move back right.
2) Scan left and update each track as required by the transitions of M. Move back right.
i) If necessary, subdivide a new square into tracks.
3. When M would halt, reformat the tape to throw away all but track 1, position the head correctly, then go to M's halt state.

## How Many Steps Does M' Take?

Let: $\quad x$ be the input string, and
$t$ be the number of steps it takes $M$ to execute.
Step 1 (initialization)
Step 2 ( computation)
Number of passes $=\mathrm{t}$
Work at each pass:

$$
\mathrm{O}(|\mathrm{x}|)
$$

$$
\begin{aligned}
2.1 & =2 \cdot(\text { length of tape }) \\
& =2 \cdot(|\mathrm{x}|+2+\mathrm{t}) \\
2.2 & =2 \cdot(|\mathrm{x}|+2+\mathrm{t})
\end{aligned}
$$

Total $=\mathrm{O}(\mathrm{t} \cdot(|\mathrm{x}|+\mathrm{t}))$
Step 3 (clean up)
O (length of tape)
Total $=\mathrm{O}(\mathrm{t} \cdot(|\mathrm{x}|+\mathrm{t}))$

Our current definition:

Proposed definition:

## Random Access Turing Machines

A random access Turing machine has:

- a fixed number of registers
- a finite length program, composed of instructions with operators such as read, write, load, store, add, sub, jump
- a tape
- a program counter

Theorem: Standard Turing machines and random access Turing machines compute the same things. Furthermore, the number of steps it takes a standard machine is bounded by a polynomial in the number of steps it takes a random access machine.

## Nondeterministic Turing Machines

A nondeterministic Turing machine is a quintuple
(K, $\Sigma, \Delta, \mathrm{s}, \mathrm{H})$
where $\mathrm{K}, \Sigma, \mathrm{s}$, and H are as for standard Turing machines, and $\Delta$ is a subset of $((\mathrm{K}-\mathrm{H}) \times \Sigma) \times(\mathrm{K} \times(\Sigma \cup\{\leftarrow, \rightarrow\}))$

What does it mean for a nondeterministic Turing machine to compute something?

- Semidecides - at least one halts.
- Decides - ?
- Computes - ?

## Nondeterministic Semideciding

Let $\mathrm{M}=(\mathrm{K}, \Sigma, \Delta, \mathrm{s}, \mathrm{H})$ be a nondeterministic Turing machine. We say that M accepts an input $w \in(\Sigma-\{\Delta, \square\}) *$ iff
( $s, \Delta D_{w}$ ) yields a least one accepting configuration.

We say that $M$ semidecides a language
$\mathrm{L} \subseteq(\Sigma-\{\Delta, \square\})^{*}$ iff
$\quad \quad$ for all $w \in(\Sigma-\{\diamond, \square\})^{*}:$
$\mathrm{w} \in \mathrm{L}$ iff
( $\mathrm{s}, \Delta \underline{\square} \mathrm{w}$ ) yields a least one halting configuration.

## An Example

$\mathrm{L}=\left\{\mathrm{w} \in\{\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}\}^{*}:\right.$ there are two of at least one letter $\}$

## Nondeterministic Deciding and Computing

M decides a language L if, for all $\mathrm{w} \in(\Sigma-\{\diamond, \square\})^{*}$ :

1. all of M's computations on whalt, and
2. $\mathrm{w} \in \mathrm{L}$ iff at least one of M's computations accepts.
$M$ computes a function $f$ if, for all $w \in(\Sigma-\{\Delta, \square\})^{*}$ :
3. all of M's computations halt, and
4. all of M's computations result in $\mathrm{f}(\mathrm{w})$

Note that all of M's computations halt iff:
There is a natural number N , depending on M and w , such that there is no configuration C satisfying $\left(s, \Delta D_{w}\right) \mid-{ }_{-}^{N} C$.

## An Example of Nondeterministic Deciding

$\mathrm{L}=\left\{\mathrm{w} \in\{0,1\}^{*}: \mathrm{w}\right.$ is the binary encoding of a composite number $\}$
M decides L by doing the following on input w :

1. Nondeterministically choose two binary numbers $1<p$, $q$, where $|p|$ and $|q| \leq|w|$, and write them on the tape, after $w$, separated by ;.

吅110011;111;1111DD
2. Multiply p and q and put the answer, A , on the tape, in place of p and q .
$\diamond \square 110011 ; 1011111 \square \square$
3. Compare $A$ and $w$. If equal, go to $y$. Else go to $n$.

## Equivalence of Deterministic and Nondeterministic Turing Machines

Theorem: If a nondeterministic Turing machine $M$ semidecides or decides a language, or computes a function, then there is a standard Turing machine $\mathrm{M}^{\prime}$ semideciding or deciding the same language or computing the same function.

Note that while nondeterminism doesn't change the computational power of a Turing Machine, it can exponentially increase its speed!

Proof: (by construction)
For semideciding: We build $\mathrm{M}^{\prime}$, which runs through all possible computations of M . If one of them halts, $\mathrm{M}^{\prime}$ halts
Recall the way we did this for FSMs: simulate being in a combination of states.
Will this work here?

What about: Try path 1. If it accepts, accept. Else Try path 2. If it accepts, accept. Else
-

## The Construction

At any point in the operation of a nondeterministic machine M , the maximum number of branches is

$$
\mathrm{r}=\quad \underset{\text { states }}{|\mathrm{K}|} \cdot \begin{aligned}
& (|\Sigma|+2) \\
& \text { actions }
\end{aligned}
$$

So imagine a table:

|  | 1 | 2 | 3 |  | r |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $(\mathrm{q} 1, \sigma 1)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ |
| $(\mathrm{q} 1, \sigma 2)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ | $(\mathrm{p}-, \sigma-)$ |
| $(\mathrm{q} 1, \sigma \mathrm{\sigma})$ |  |  |  |  |  |
| $(\mathrm{q} 2, \sigma 1)$ |  |  |  |  |  |
|  |  |  |  |  |  |
| $(\mathrm{q}\|\mathrm{K}\|, \sigma \mathrm{Cn})$ |  |  |  |  |  |

Note that if, in some configuration, there are not $r$ different legal things to do, then some of the entries on that row will repeat.
The Construction, Continued
$M_{d}: \quad$ (suppose $\left.r=6\right)$
Tape 1:

| Input |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 3 | 2 | 6 | 5 | 4 | 3 | 6 |

$\mathrm{M}_{\mathrm{d}}$ chooses its 1st move from column 1
$\mathrm{M}_{\mathrm{d}}$ chooses its 2nd move from column 3
$\mathrm{M}_{\mathrm{d}}$ chooses its 3rd move from column 2
-
until there are no more numbers on Tape 2
$\mathrm{M}_{\mathrm{d}}$ either:

- discovers that M would accept, or
- comes to the end of Tape 2.

In either case, it halts.

## The Construction, Continued

$\mathrm{M}^{\prime}$ (the machine that simulates $\mathbf{M}$ ):

Steps of M':
write $\varepsilon$ on Tape 3
until $\mathrm{M}_{\mathrm{d}}$ accepts do
(1) copy Input from Tape 1 to Tape 2
(2) run $M_{d}$
(3) if $M_{d}$ accepts, exit
(4) otherwise, generate lexicographically next string on Tape 3 .

| Pass | 1 | 2 | 3 |  | 7 | 8 | 9 |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Tape3 | $\varepsilon$ | 1 | 2 | $\ldots$ | 6 | 11 | 12 | $\ldots$ | 2635 |

## Nondeterministic Algorithms

## Other Turing Machine Extensions

Multiple heads (on one tape)
Emulation strategy: Use tracks to keep track of tape heads. (See book)
Multiple tapes, multiple heads
Emulation strategy: Use tracks to keep track of tapes and tape heads.
Two-dimensional semi-infinite "tape"
Emulation strategy: Use diagonal enumeration of two-dimensional grid. Use second tape to help you keep track of where the tape head is. (See book)

Two-dimensional infinite "tape" (really a sheet)
Emulation strategy: Use modified diagonal enumeration as with the semi-infinite case.

## What About Turing Machine Restrictions?

Can we make Turing machines even more limited and still get all the power?
Example:
We allow a tape alphabet of arbitrary size. What happens if we limit it to:

- One character?
- Two characters?
- Three characters?

## Problem Encoding, TM Encoding, and the Universal TM

Read K \& S 5.1 \& 5.2.

## Encoding a Problem as a Language

A Turing Machines deciding a language is analogous to the TM solving a decision problem.
Problem: Is the number $n$ prime?
Instance of the problem: Is the number 9 prime?
Encoding of the problem, $\langle\mathbf{n}\rangle: \mathrm{n}$ as a binary number. Example: 1001

Problem: Is an undirected graph G connected?
Instance of the problem: Is the following graph connected?

Encoding of the problem, $\langle\mathbf{G}\rangle$ :

1) $|\mathrm{V}|$ as a binary number
2) A list of edges represented by pairs of binary numbers being the vertex numbers that the edge connects
3) All such binary numbers are separated by " $/$ ".

Example: 101/1/10/10/11/1/100/10/101

## Problem View vs. Language View

Problem View: It is unsolvable whether a Turing Machine halts on a given input. This is called the Halting Problem.
Language View: Let $\mathrm{H}=\{\langle\mathrm{M}, \mathrm{w}\rangle$ : TM M halts on input string w$\}$
H is recursively enumerable but not recursive.

## The Universal Turing Machine

Problem: All our machines so far are hardwired.
Question: Does it make sense to talk about a programmable Turing machine that accepts as input
program input string
executes the program, and outputs
output string
Yes, it's called the Universal Turing Machine.
Notice that the Universal Turing machine semidecides $H=\{\langle M, w\rangle: T M M$ halts on input string $w\}=L(U)$.
To define the Universal Turing Machine $U$ we need to do two things:

1. Define an encoding operation for Turing machines.
2. Describe the operation of $U$ given an input tape containing two inputs:

- encoded Turing machine M,
- encoded input string to be given to M.

## Encoding a Turing Machine M

We need to describe $\mathrm{M}=(\mathrm{K}, \Sigma, \delta, \mathrm{s}, \mathrm{H})$ as a string. To do this we must:

1. Encode $\delta$
2. Specify s.
3. Specify H (and y and $n$, if applicable)
4. To encode $\delta$, we need to:
5. Encode the states
6. Encode the tape alphabet
7. Specify the transitions
1.1 Encode the states as
qs $: s \in\{0,1\}^{+}$and
$|s|=i$ and
$i$ is the smallest integer such that $2^{i} \geq|K|$
Example: 9 states $i=4$
$\mathrm{s}=\mathrm{q} 0000$,
remaining states: q0001, q0010, q0011,
q0100, q0101, q0110, q0111, q1000

## Encoding a Turing Machine M, Continued

1.2 Encode the tape alphabet as
as $: s \in\{0,1\}^{+}$and
$|\mathrm{s}|=\mathrm{j}$ and
$j$ is the smallest integer such that $2^{j} \geq|\Sigma|+2 \quad$ (the +2 allows for $\leftarrow$ and $\rightarrow$ )
Example: $\Sigma=\{\diamond, \square, a, b\} \quad j=3$

$$
\begin{array}{ll}
\square= & \mathrm{a} 000 \\
\diamond= & \mathrm{a} 001 \\
\leftarrow= & \mathrm{a} 010 \\
\rightarrow= & \mathrm{a} 011 \\
\mathrm{a}= & \mathrm{a} 100 \\
\mathrm{~b}= & \mathrm{a} 101
\end{array}
$$

## Encoding a Turing Machine M, Continued

1.3 Specify transitions as (state, input, state, output)

Example: (q00,a000,q11,a000)
2. Specify s as q0 $0^{i}$
3. Specify H:

- States with no transitions out are in H .
- If $M$ decides a language, then $H=\{y, n\}$, and we will adopt the convention that $y$ is the lexicographically smaller of the two states.

$$
\mathrm{y}=\mathrm{q} 010 \quad \mathrm{n}=\mathrm{q} 011
$$

## Encoding Input Strings

We encode input strings to a machine M using the same character encoding we use for M .
For example, suppose that we are using the following encoding for symbols in M :

| symbol | representation |
| :---: | :---: |
| $\square$ | a 000 |
| $\diamond$ | a 001 |
| $\leftarrow$ | a 010 |
| $\rightarrow$ | a 011 |
| a | a 100 |

Then we would represent the string $\mathrm{s}=\widehat{\mathrm{aa} \square \mathrm{a} \text { as } \quad \mathrm{s}=\mathrm{s} "=\langle\mathrm{s}\rangle=\mathrm{a} 001 \mathrm{a} 100 \mathrm{a} 100 \mathrm{a} 000 \mathrm{a} 100010}$

## An Encoding Example

Consider $\mathrm{M}=(\{\mathrm{s}, \mathrm{q}, \mathrm{h}\},\{\square, \diamond, \mathrm{a}\}, \delta, \mathrm{s},\{\mathrm{h}\})$, where $\delta=$

| state | symbol | $\delta$ |
| :---: | :---: | :---: |
| s | a | $(\mathrm{q}, \square)$ |
| s | $\square$ | $(\mathrm{h}, \square)$ |
| s | $\diamond$ | $(\mathrm{s}, \rightarrow)$ |
| q | a | $(\mathrm{s}, \mathrm{a})$ |
| q | $\square$ | $(\mathrm{s}, \rightarrow)$ |
| q | $\diamond$ | $(\mathrm{q}, \rightarrow)$ |

| state/symbol | representation |
| :---: | :---: |
| s | q 00 |
| q | q 01 |
| h | q 11 |
| $\square$ | a 000 |
| $\diamond$ | a 001 |
| $\leftarrow$ | a 010 |
| $\rightarrow$ | a 011 |
| a | a 100 |

The representation of $M$, denoted, " M ", $\langle\mathrm{M}\rangle$, or sometimes $\rho(\mathrm{M})=$ (q00,a100,q01,a000), (q00,a000,q11,a000), (q00,a001,q00,a011), (q01,a100,q00,a100), (q01,a000,q00,a011), (q01,a001,q01,a011)

## Another Win of Encoding

One big win of defining a way to encode any Turing machine M :

- It will make sense to talk about operations on programs (Turing machines). In other words, we can talk about some Turing machine T that takes another Turing machine (say $\mathrm{M}_{1}$ ) as input and transforms it into a different machine (say $\mathrm{M}_{2}$ ) that performs some different, but possibly related task.

Example of a transforming TM T:
Input: a machine $\mathrm{M}_{1}$ that reads its input tape and performs some operation P on it.
Output: a machine $\mathrm{M}_{2}$ that performs P on an empty input tape:

## The Universal Turing Machine

The specification for U :
U("M" "w") = "M(w)"

| $\diamond$ | "M ---- |  |  | M ${ }^{\prime \prime}$ | 'w- |  | -----w" | $\square$ | $\square$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |
|  | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |  |  |
|  | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |  |  |
|  | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |  |  |
|  | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |  |  |

| $\diamond$ | " | 口" | "W----- | ------- | ---w" | $\square$ | $\square$ | $\square$ | $\square$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |
|  | "M --- |  | -------- | M ${ }^{\prime}$ | $\square$ | $\square$ | $\square$ |  |  |
|  | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |
|  | q | 0 | 0 | 0 | $\square$ | $\square$ | $\square$ |  |  |
|  |  | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |  |  |

Initialization of U :

1. Copy " M " onto tape 2
2. Insert " $\langle\square$ " at the left edge of tape 1 , then shift w over.
3. Look at "M", figure out what i is, and write the encoding of state s on tape 3.

## The Operation of $\mathbf{U}$

| $\bigcirc$ | a | 0 | 0 | 1 | a | 0 | 0 | $\square$ | $\square$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |
|  | "M ---- |  |  | M ${ }^{\prime \prime}$ | $\square$ | $\square$ | $\square$ |  |  |
|  | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |
|  | q | 0 | 0 | 0 | $\square$ | $\square$ | $\square$ |  |  |
|  | 1 | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ | $\square$ |  |  |

Simulate the steps of M:

1. Start with the heads:
tape 1: the a of the character being scanned,
tape 2: far left
tape 3: far left
2. Simulate one step:
3. Scan tape 2 for a quadruple that matches current state, input pair.
4. Perform the associated action, by changing tapes 1 and 3. If necessary, extend the tape.
5. If no quadruple found, halt. Else go back to 2.

## An Example

Tape 1: a001a000a100a100a000a100

Tape 2: (q00,a000,q11,a000), (q00,a001, q00,a011),
(q00, a100, q01, a000), (q01, a000, q00, a011),
(q01, a001,q01,a011), (q01, a100,q00, a100)
Tape 3: q01

Result of simulating the next step:
Tape 1: a001a000a100a100a000a100

Tape 3: q00

If A Universal Machine is Such a Good Idea ...
Could we define a Universal Finite State Machine?
Such a FSM would accept the language $L=\{" F "$ "w" : $\quad \mathrm{F}$ is a finite state machine, and $w \in L(F)\}$

## Grammars and Turing Machines

Do Homework 20.

## Grammars, Recursively Enumerable Languages, and Turing Machines

## Unrestricted Grammars

An unrestricted, or Type 0 , or phrase structure grammar G is a quadruple
(V, $\Sigma, \mathrm{R}, \mathrm{S}$ ), where

- V is an alphabet,
- $\quad \Sigma$ (the set of terminals) is a subset of V ,
- $\quad \mathrm{R}$ (the set of rules) is a finite subset of

| - | $\left(\mathrm{V}^{*}\right.$ | $(\mathrm{V}-\Sigma)$ | $\left.\mathrm{V}^{*}\right)$ | $\times$ |
| :--- | :---: | :---: | :--- | ---: |
| context | N | context | $\rightarrow$ | $\mathrm{V}^{*}$, |
| result |  |  |  |  |

- $\quad \mathrm{S}$ (the start symbol) is an element of $\mathrm{V}-\Sigma$.

We define derivations just as we did for context-free grammars.
The language generated by G is

$$
\left\{w \in \Sigma^{*}: S \Rightarrow_{G}{ }^{*} w\right\}
$$

There is no notion of a derivation tree or rightmost/leftmost derivation for unrestricted grammars.

## Unrestricted Grammars

Example: $L=a^{n} b^{n} c^{n}, n>0$
$\mathrm{S} \rightarrow \mathrm{aBSc}$
$\mathrm{S} \rightarrow \mathrm{aBc}$
$\mathrm{Ba} \rightarrow \mathrm{aB}$
$\mathrm{Bc} \rightarrow \mathrm{bc}$
$\mathrm{Bb} \rightarrow \mathrm{bb}$

## Another Example

$\mathrm{L}=\left\{\mathrm{w} \in\{\mathrm{a}, \mathrm{b}, \mathrm{c}\}^{+}:\right.$number of a's, b 's and c 's is the same $\}$
$\mathrm{S} \rightarrow \mathrm{ABCS}$
$S \rightarrow A B C$
$\mathrm{AB} \rightarrow \mathrm{BA}$
$\mathrm{CA} \rightarrow \mathrm{AC}$
$\mathrm{BC} \rightarrow \mathrm{CB}$
$\mathrm{A} \rightarrow \mathrm{a}$
B $\rightarrow$ b
$\mathrm{C} \rightarrow \mathrm{c}$
$\mathrm{BA} \rightarrow \mathrm{AB}$

## A Strong Procedural Feel

Unrestricted grammars have a procedural feel that is absent from restricted grammars.
Derivations often proceed in phases. We make sure that the phases work properly by using nonterminals as flags that we're in a particular phase.

It's very common to have two main phases:

- Generate the right number of the various symbols.
- Move them around to get them in the right order.

No surprise: unrestricted grammars are general computing devices.

## Equivalence of Unrestricted Grammars and Turing Machines

Theorem: A language is generated by an unrestricted grammar if and only if it is recursively enumerable (i.e., it is semidecided by some Turing machine M ).

## Proof:

Only if (grammar $\rightarrow \mathrm{TM}$ ): by construction of a nondeterministic Turing machine.
If ( $\mathrm{TM} \rightarrow$ grammar): by construction of a grammar that mimics backward computations of M .

$$
\text { Proof that Grammar } \rightarrow \text { Turing Machine }
$$

Given a grammar G, produce a Turing machine $M$ that semidecides $L(G)$.
$M$ will be nondeterministic and will use two tapes:

For each nondeterministic "incarnation":

- Tape 1 holds the input.
- Tape 2 holds the current state of a proposed derivation.

At each step, $M$ nondeterministically chooses a rule to try to apply and a position on tape 2 to start looking for the left hand side of the rule. Or it chooses to check whether tape 2 equals tape 1. If any such machine succeeds, we accept. Otherwise, we keep looking.

## Proof that Turing Machine $\rightarrow$ Grammar

Suppose that M semidecides a language L (it halts when fed strings in L and loops otherwise). Then we can build M' that halts in the configuration (h, $\vee \underline{\square}$ ).

We will define G so that it simulates $\mathrm{M}^{\prime}$ backwards.
We will represent the configuration (q, $\langle$ uaw) as
>uaqw<
M'
goes from

Then, if $w \in L$, we require that our grammar produce a derivation of the form
$\mathrm{S} \Rightarrow_{\mathrm{G}}>\mathrm{D}_{\mathrm{h}}<\quad$ (produces final state of $\mathrm{M}^{\prime}$ )
$\Rightarrow \mathrm{G}^{*}>\mathrm{a}_{\mathrm{abq}}<$ (some intermediate state of $\mathrm{M}^{\prime}$ )
$\Rightarrow_{\mathrm{G}} *>\square_{\mathrm{sw}}<$ (the initial state of $\mathrm{M}^{\prime}$ )
$\Rightarrow{ }_{\mathrm{G}} \mathrm{W}<\quad$ (via a special rule to clean up $>\square$ s)
$\Rightarrow \quad{ }_{\mathrm{G}} \mathrm{W} \quad$ (via a special rule to clean up $<$ )

## The Rules of $\mathbf{G}$

$\mathrm{S} \rightarrow>\mathrm{D}<\quad$ (the halting configuration)
$>\square \mathrm{s} \rightarrow \varepsilon \quad$ (clean-up rules to be applied at the end)
$<\rightarrow \varepsilon$
Rules that correspond to $\delta$ :
If $\delta(q, a)=(p, b): \quad b p \rightarrow a q$
If $\delta(\mathrm{q}, \mathrm{a})=(\mathrm{p}, \rightarrow): \quad \mathrm{abp} \rightarrow \mathrm{aqb} \quad \forall \mathrm{b} \in \Sigma$
$\mathrm{a} \square \mathrm{p}<\rightarrow \mathrm{aq}<$
If $\delta(q, a)=(p, \leftarrow), a \neq \square$
$\mathrm{pa} \rightarrow \mathrm{aq}$
If $\delta(\mathrm{q}, \square)=(\mathrm{p}, \leftarrow)$
$\mathrm{p} \square \mathrm{b} \rightarrow \square \mathrm{qb} \quad \forall \mathrm{b} \in \Sigma$
$\mathrm{p}<\rightarrow \square \mathrm{q}<$

## A REALLY Simple Example

$\mathrm{L}=\mathrm{a}^{*}$
$\mathrm{S} \rightarrow>\mathrm{D}<$
$>\square \mathrm{as} \rightarrow \varepsilon$
$<\rightarrow \varepsilon$
(1)
$\square \square q \rightarrow \square \mathrm{~s} \square$
$\square_{\text {aq }} \rightarrow \square_{\text {sa }}$
$\square \mathrm{al}_{\mathrm{q}}<\rightarrow \mathrm{D}_{\mathrm{s}}<$
(2)
$\mathrm{a} \square \mathrm{q} \rightarrow \mathrm{aq} \square$
aaq $\rightarrow$ aqa
a ■ $\mathrm{q}<\rightarrow \mathrm{aq}<$
(3) $\quad \mathrm{ta} \rightarrow \square \mathrm{q} \square$
$\mathrm{t} \square \mathrm{a} \rightarrow \square \mathrm{qa}$
$\mathrm{t}<\rightarrow \square \mathrm{q}<$
(4) $\quad \mathrm{p} \rightarrow \mathrm{at}$
(5) $\quad \square h \rightarrow \square \mathrm{t}$
(6) $\mathrm{t} \square \rightarrow \square \mathrm{p} \square$
$\mathrm{t} \square \mathrm{a} \rightarrow$ Пра
$\mathrm{t}<\rightarrow \square \mathrm{p}<$

## Working It Out

| $\begin{aligned} & \mathrm{S} \rightarrow>\square \mathrm{h}< \\ & >\square_{\mathrm{s}} \rightarrow \varepsilon \\ & <\rightarrow \varepsilon \end{aligned}$ |
| :---: |
|  |  |
|  |  |

(1) $\square \square q \rightarrow \square s \square \quad 4$ $\square \mathrm{aq} \rightarrow$ ®a $^{\text {sa }} \quad 5$ $\square \square_{q}<\rightarrow \square \mathrm{m}<\quad 6$
(2)
$\mathrm{a} \square \mathrm{q} \rightarrow \mathrm{aq} \mathrm{\square} \quad 7$
aaq $\rightarrow$ aqa $\quad 8$
$\mathrm{a} \square \mathrm{q}<\rightarrow \mathrm{aq}<\quad 9$
(3) $\mathrm{t} \square \square \square \mathrm{q} \square \mathrm{D}$ $\mathrm{t} \square \mathrm{a} \rightarrow$ qa $\quad 11$
$\mathrm{t}<\rightarrow \mathrm{Dq}_{\mathrm{q}}<\quad 12$
(4) $\quad \mathrm{p} \rightarrow \mathrm{at} \quad 13$
(5) $\square \mathrm{h} \rightarrow \square \mathrm{t} \quad 14$
(6) $\mathrm{t} \square \mathrm{\square} \rightarrow \mathrm{Dp}$ - 15
$\mathrm{t} \square \mathrm{a} \rightarrow \square \mathrm{pa} \quad 16$
$\mathrm{t}<\rightarrow \square \mathrm{p}<\quad 17$

| > ${ }_{\text {saa }}$ | 1 | S | $\Rightarrow>$ 鸟 $<$ | 1 |
| :---: | :---: | :---: | :---: | :---: |
| >- aqa< | 2 |  | $\Rightarrow>\square$ | 14 |
| >-aaq< | 2 |  | $\Rightarrow>\square \underline{\mathrm{p}}<$ | 17 |
| $>\square \mathrm{aa} \mathrm{Oq}_{\mathrm{q}}<$ | 3 |  | $\Rightarrow>\square \mathrm{at}$ | 13 |
| >Dat< | 4 |  | $\Rightarrow>\square \mathrm{a}$ ■ p | 17 |
| $>\square \mathrm{a}$ ¢p | 6 |  | $\Rightarrow>$ aat $<$ | 13 |
| > -at< | 4 |  | $\Rightarrow>\mathrm{aan}_{\mathrm{al}}<$ | 12 |
| $>\square \square \mathrm{p}<$ | 6 |  | $\Rightarrow>\square \underline{\text { aaq }}<$ | 9 |
| >Dt< | 5 |  | $\Rightarrow>\square$ aqa $<$ | 8 |
| >Dh< |  |  | $\Rightarrow \geq \square_{\text {saa }}<$ | 5 |
|  |  |  | $\Rightarrow \mathrm{a}<$ | 2 |
|  |  |  | $\Rightarrow \mathrm{aa}$ | 3 |

## An Alternative Proof

An alternative is to build a grammar $G$ that simulates the forward operation of a Turing machine M. It uses alternating symbols to represent two interleaved tapes. One tape remembers the starting string, the other "working" tape simulates the run of the machine.

The first (generate) part of G:
Creates all strings over $\Sigma^{*}$ of the form

$$
w=\diamond \Delta \square \square Q s a_{1} a_{1} a_{2} a_{2} a_{3} a_{3} \square \ldots
$$

The second (test) part of $G$ simulates the execution of $M$ on a particular string $w$. An example of a partially derived string:
$\diamond \diamond \square \square$ a 1 b 2 cc b 4 Q3a3

Examples of rules:
bb Q $4 \rightarrow$ b 4 Q 4 (rewrite b as 4)
b 4 Q $3 \rightarrow$ Q 3 b 4 (move left)
The third (cleanup) part of $G$ erases the junk if $M$ ever reaches $h$.
Example rule:
\# h a $1 \rightarrow \mathrm{a} \# \mathrm{~h} \quad$ (sweep \# h to the right erasing the working "tape")

## Computing with Grammars

We say that $\mathbf{G}$ computes $\mathbf{f}$ if, for all $\mathrm{w}, \mathrm{v} \in \Sigma^{*}$,
$\mathrm{SwS} \Rightarrow{ }_{\mathrm{G}}{ }^{*} \mathrm{v}$ iff $\mathrm{v}=\mathrm{f}(\mathrm{w})$
Example:

```
\(\mathrm{S} 1 \mathrm{~S} \quad \Rightarrow_{\mathrm{G}}{ }^{*} 11\)
S11S \(\Rightarrow_{\mathrm{G}}{ }^{*} 111\)
\(\mathrm{f}(\mathrm{x})=\operatorname{succ}(\mathrm{x})\)
```

A function $f$ is called grammatically computable iff there is a grammar $G$ that computes it.
Theorem: A function f is recursive iff it is grammatically computable. In other words, if a Turing machine can do it, so can a grammar.

## Example of Computing with a Grammar

$f(x)=2 x$, where $x$ is an integer represented in unary
$\mathrm{G}=(\{\mathrm{S}, 1\},\{1\}, \mathrm{R}, \mathrm{S})$, where $\mathrm{R}=$
S1 $\rightarrow 11 \mathrm{~S}$
$\mathrm{SS} \rightarrow \varepsilon$

Example:
Input:
S111S

Output:

## More on Functions: Why Have We Been Using Recursive as a Synonym for Computable? Primitive Recursive Functions

Define a set of basic functions:

- $\operatorname{zero}_{k}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}\right)=0$
- $\quad$ identity $_{\mathrm{k}, \mathrm{j}}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}\right)=\mathrm{n}_{\mathrm{j}}$
- $\quad \operatorname{successor}(\mathrm{n})=\mathrm{n}+1$

Combining functions:

- Composition of $g$ with $h_{1}, h_{2}, \ldots h_{k}$ is

$$
\mathrm{g}\left(\mathrm{~h}_{1}(\quad), \mathrm{h}_{2}(\quad), \ldots \mathrm{h}_{\mathrm{k}}(\quad)\right)
$$

- Primitive recursion of $f$ in terms of $g$ and $h$ :
$\mathrm{f}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}, \quad 0\right)=\mathrm{g}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}\right)$
$\mathrm{f}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}, \mathrm{m}+1\right)=\mathrm{h}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}, \mathrm{m}, \mathrm{f}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}, \mathrm{m}\right)\right)$
Example: $\quad \operatorname{plus}(\mathrm{n}, 0)=\mathrm{n}$
$\operatorname{plus}(\mathrm{n}, \mathrm{m}+1)=\operatorname{succ}(\operatorname{plus}(\mathrm{n}, \mathrm{m}))$
Primitive Recursive Functions and Computability
Trivially true: all primitive recursive functions are Turing computable.
What about the other way: Not all Turing computable functions are primitive recursive.

## Proof:

Lexicographically enumerate the unary primitive recursive functions, $f_{0}, f_{1}, f_{2}, f_{3}, \ldots$.
Define $g(n)=f_{n}(n)+1$.
G is clearly computable, but it is not on the list. Suppose it were $f_{m}$ for some $m$. Then

$$
\mathrm{f}_{\mathrm{m}}(\mathrm{~m})=\mathrm{f}_{\mathrm{m}}(\mathrm{~m})+1, \text { which is absurd. }
$$

|  | 0 | 1 | 2 | 3 | 4 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{f}_{0}$ |  |  |  |  |  |
| $\mathrm{f}_{1}$ |  |  |  |  |  |
| $\mathrm{f}_{2}$ |  |  |  |  |  |
| $\mathrm{f}_{3}$ |  |  |  | 27 |  |
| $\mathrm{f}_{4}$ |  |  |  |  |  |

Suppose $g$ is $f_{3}$. Then $g(3)=27+1=28$. Contradiction.

## Functions that Aren't Primitive Recursive

Example: Ackermann's function: $\quad A(0, y)=y+1$
$A(x+1,0)=A(x, 1)$
$\mathrm{A}(\mathrm{x}+1, \mathrm{y}+1)=\mathrm{A}(\mathrm{x}, \mathrm{A}(\mathrm{x}+1, \mathrm{y}))$

|  | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathbf{0}$ | 1 | 2 | 3 | 4 | 5 |  |
| $\mathbf{1}$ | 2 | 3 | 4 | 5 | 6 |  |
| $\mathbf{2}$ | 3 | 5 | 7 | 9 | 11 |  |
| $\mathbf{3}$ | 5 | 13 | 29 | 61 | 125 |  |
| $\mathbf{4}$ | 13 | 65533 | $2^{65536}-3 \quad *$ | $2^{2^{65336}}-3 \quad \#$ | $2^{2^{65536}}-3 \quad \%$ |  |

[^0]$10^{17}$ seconds since big bang
$10^{87}$ protons and neutrons
$10^{-23}$ light seconds $=$ width of proton or neutron
Thus writing digits at the speed of light on all protons and neutrons in the universe (all lined up) starting at the big bang would have produced $10^{127}$ digits.

## Recursive Functions

A function is $\boldsymbol{\mu}$-recursive if it can be obtained from the basic functions using the operations of:

- Composition,
- Recursive definition, and
- Minimalization of minimalizable functions:

The minimalization of $g$ (of $k+1$ arguments) is a function $f$ of $k$ arguments defined as: $\mathrm{f}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}\right)=\quad$ the least m such at $\mathrm{g}\left(\mathrm{n}_{1}, \mathrm{n}_{2}, \ldots \mathrm{n}_{\mathrm{k}}, \mathrm{m}\right)=1$, if such an $m$ exists, 0 otherwise

A function $g$ is minimalizable iff for every $n_{1}, n_{2}, \ldots n_{k}$, there is an $m$ such that $g\left(n_{1}, n_{2}, \ldots n_{k}, m\right)=1$.
Theorem: A function is $\mu$-recursive iff it is recursive (i.e., computable by a Turing machine).
Partial Recursive Functions
Consider the following function f :
$f(n)=1$ if $T M(n)$ halts on a blank tape
0 otherwise
The domain of f is the natural numbers. Is f recursive?

Theorem: There are uncountably many partially recursive functions (but only countably many Turing machines).
Functions and Machines

## Languages and Machines

Is There Anything In Between CFGs and Unrestricted Grammars?
Answer: yes, various things have been proposed.

## Context-Sensitive Grammars and Languages:

A grammar $G$ is context sensitive if all productions are of the form

$$
\begin{aligned}
& \mathrm{x} \rightarrow \mathrm{y} \\
& \text { and }|\mathrm{x}| \leq|\mathrm{y}|
\end{aligned}
$$

In other words, there are no length-reducing rules.

A language is context sensitive if there exists a context-sensitive grammar for it.
Examples:

$$
\begin{aligned}
& \mathrm{L}=\left\{\mathrm{a}^{\mathrm{n}} \mathrm{~b}^{\mathrm{n}} \mathrm{c}^{\mathrm{n}}, \mathrm{n}>0\right\} \\
& \mathrm{L}=\left\{\mathrm{w} \in\{\mathrm{a}, \mathrm{~b}, \mathrm{c}\}^{+}: \text {number of a's, } \mathrm{b} \text { 's and c's is the same }\right\}
\end{aligned}
$$

## Context-Sensitive Languages are Recursive

The basic idea: To decide if a string $w$ is in $L$, start generating strings systematically, shortest first. If you generate $w$, accept. If you get to strings that are longer than $w$, reject.

## Linear Bounded Automata

A linear bounded automaton is a nondeterministic Turing machine the length of whose tape is bounded by some fixed constant $k$ times the length of the input.

Example:

$$
\mathrm{L}=\left\{\mathrm{a}^{\mathrm{n}} \mathrm{~b}^{\mathrm{n}} \mathrm{c}^{\mathrm{n}}: \mathrm{n} \geq 0\right\}
$$

$\Delta$ Daabbcc $\square$ -

## Context-Sensitive Languages and Linear Bounded Automata

Theorem: The set of context-sensitive languages is exactly the set of languages that can be accepted by linear bounded automata.
Proof: (sketch) We can construct a linear-bounded automaton B for any context-sensitive language L defined by some grammar G. We build a machine B with a two track tape. On input w, B keeps w on the first tape. On the second tape, it nondeterministically constructs all derivations of G. The key is that as soon as any derivation becomes longer than $|\mathrm{w}|$ we stop, since we know it can never get any shorter and thus match $w$. There is also a proof that from any lba we can construct a contextsensitive grammar, analogous to the one we used for Turing machines and unrestricted grammars.

Theorem: There exist recursive languages that are not context sensitive.

## Languages and Machines

## Undecidabilty

Read K \& S 5.1, 5.3, \& 5.4.
Read Supplementary Materials: Recursively Enumerable Languages, Turing Machines, and Decidability. Do Homeworks $21 \& 22$.

Church's Thesis<br>(Church-Turing Thesis)

An algorithm is a formal procedure that halts.
The Thesis: Anything that can be computed by any algorithm can be computed by a Turing machine.

Another way to state it: All "reasonable" formal models of computation are equivalent to the Turing machine.
This isn't a formal statement, so we can't prove it. But many different computational models have been proposed and they all turn out to be equivalent.

Examples:

- unrestricted grammars
- lambda calculus
- cellular automata
- DNA computing
- quantum computing (?)

## The Unsolvability of the Halting Problem

Suppose we could implement the decision procedure
$\operatorname{HALTS}(\mathrm{M}, \mathrm{x})$
M : string representing a Turing Machine
x : string representing the input for M
If $M(x)$ halts then True
else False
Then we could define
TROUBLE(x)
x : string
If $\operatorname{HALTS}(\mathrm{x}, \mathrm{x})$ then loop forever
else halt
So now what happens if we invoke TROUBLE("TROUBLE"), which invokes HALTS("TROUBLE", "TROUBLE")
If HALTS says that TROUBLE halts on itself then TROUBLE loops. IF HALTS says that TROUBLE loops, then TROUBLE halts. Either way, we reach a contradiction, so $\operatorname{HALTS}(M, x)$ cannot be made into a decision procedure.

## Another View

The Problem View: The halting problem is undecidable.

## The Language View: Let $\mathrm{H}=$

\{"M" "w" : TM M halts on input string w\}
H is recursively enumerable but not recursive.
Why?
$H$ is recursively enumerable because it can be semidecided by U , the Universal Turing Machine.
But $H$ cannot be recursive. If it were, then it would be decided by some TM MH. But MH("M" "w") would have to be: If M is not a syntactically valid TM, then False.
else HALTS("M" "w")

But we know cannot that HALTS cannot exist.

## If H were Recursive

$\mathrm{H}=\{$ "M" "w" : TM M halts on input string w $\}$
Theorem: If H were also recursive, then every recursively enumerable language would be recursive.
Proof: Let L be any RE language. Since L is RE, there exists a TM M that semidecides it.
Suppose H is recursive and thus is decided by some TM O (oracle).

We can build a TM M' from $M$ that decides L:

1. M' transforms its input tape from $\diamond \underline{\square} \square$ to $\diamond \square " M " " w " \square$.
2. $\mathrm{M}^{\prime}$ invokes O on its tape and returns whatever answer O returns.

So, if H were recursive, all RE languages would be. But it isn't.

## Undecidable Problems, Languages that Are Not Recursive, and Partial Functions

The Problem View: The halting problem is undecidable.

The Language View: Let $\mathrm{H}=$
\{"M" "w" : TM M halts on input string w\}
H is recursively enumerable but not recursive.
The Functional View: Let $\mathrm{f}(\mathrm{w})=\mathrm{M}(\mathrm{w})$
f is a partial function on $\Sigma^{*}$

"M""w" pairs

## Other Undecidable Problems About Turing Machines

- Given a Turing machine $\mathbf{M}$, does M halt on the empty tape?
- Given a Turing machine $\mathbf{M}$, is there any string on which M halts?
- Given a Turing machine M , does M halt on every input string?
- Given two Turing machines $\mathrm{M}_{1}$ and $\mathrm{M}_{2}$, do they halt on the same input strings?
- Given a Turing machine M , is the language that M semidecides regular? Is it context-free? Is it recursive?

## Post Correspondence Problem

Consider two lists of strings over some alphabet $\Sigma$. The lists must be finite and of equal length.
$\mathrm{A}=\mathrm{x}_{1}, \mathrm{x}_{2}, \mathrm{x}_{3}, \ldots, \mathrm{x}_{\mathrm{n}}$
$B=y_{1}, y_{2}, y_{3}, \ldots, y_{n}$
Question: Does there exist some finite sequence of integers that can be viewed as indexes of A and B such that, when elements of A are selected as specified and concatenated together, we get the same string we get when elements of B are selected also as specified?

For example, if we assert that $1,3,4$ is such a sequence, we're asserting that $x_{1} x_{3} x_{4}=y_{1} y_{3} y_{4}$
Any problem of this form is an instance of the Post Correspondence Problem.
Is the Post Correspondence Problem decidable?

## Post Correspondence Problem Examples

| $\mathbf{i}$ | A | $\mathbf{B}$ |
| :--- | :--- | :--- |
| 1 | 1 | 111 |
| 2 | 10111 | 10 |
| 3 | 10 | 0 |

| $\mathbf{i}$ | $\mathbf{A}$ | $\mathbf{B}$ |
| :--- | :--- | :--- |
| 1 | 10 | 101 |
| 2 | 011 | 11 |
| 3 | 101 | 011 |

## Some Languages Aren't Even Recursively Enumerable

A pragmatically non RE language: $L_{1}=\{(i, j): i, j$ are integers where the low order five digits of $i$ are a street address number and $j$ is the number of houses with that number on which it rained on November 13, 1946 \}

An analytically non RE language: $\mathrm{L}_{2}=\{\mathrm{x}: \mathrm{x}=$ " M " of a Turing machine M and $\mathrm{M}($ " M ") does not halt $\}$
Why isn't $L_{2}$ RE? Suppose it were. Then there would be a TM M* that semidecides $L_{2}$. Is " $\mathrm{M}^{*}$ "in $\mathrm{L}_{2}$ ?

- If it is, then $\mathbf{M}^{*}\left(" M^{*}\right.$ ") halts (by the definition of $M^{*}$ as a semideciding machine for $L_{2}$ )
- But, by the definition of $L_{2}$, if " $M^{* "} \in L_{2}$, then $M^{*}\left(" M^{*} "\right)$ does not halt.

Contradiction. So $L_{2}$ is not RE.

## Another Non RE Language

## $\overline{\mathrm{H}}$

Why not?

## Reduction

Let $L_{1}, L_{2} \subseteq \Sigma^{*}$ be languages. A reduction from $L_{1}$ to $L_{2}$ is a recursive function $\tau$ : $\Sigma^{*} \rightarrow \Sigma^{*}$ such that $x \in L_{1}$ iff $\tau(x) \in L_{2}$.
Example:

$$
\begin{array}{cc}
\mathrm{L}_{1}=\{\mathrm{a}, \mathrm{~b}: \mathrm{a}, \mathrm{~b} \in \mathrm{~N}: \mathrm{b}=\mathrm{a}+1\} & \\
\Downarrow & \tau=\text { Succ } \\
\Downarrow & \text { a, b becomes } \quad \operatorname{Succ}(\mathrm{a}), \mathrm{b} \\
\mathrm{~L}_{2}=\{\mathrm{a}, \mathrm{~b}: \mathrm{a}, \mathrm{~b} \in \mathrm{~N}: \mathrm{a}=\mathrm{b}\} &
\end{array}
$$

If there is a Turing machine $M_{2}$ to decide $L_{2}$, then $I$ can build a Turing machine $M_{1}$ to decide $L_{1}$ :

1. Take the input and apply Succ to the first number.
2. Invoke $\mathrm{M}_{2}$ on the result.
3. Return whatever answer $\mathrm{M}_{2}$ returns.

## Reductions and Recursive Languages

Theorem: If there is a reduction from $L_{1}$ to $L_{2}$ and $L_{2}$ is recursive, then $L_{1}$ is recursive.

Theorem: If there is a reduction from $L_{1}$ to $L_{2}$ and $L_{1}$ is not recursive, then $L_{2}$ is not recursive.

## Reductions and RE Languages

Theorem: If there is a reduction from $L_{1}$ to $L_{2}$ and $L_{2}$ is $R E$, then $L_{1}$ is RE.

Theorem: If there is a reduction from $L_{1}$ to $L_{2}$ and $L_{1}$ is not $R E$, then $L_{2}$ is not RE.

## Can it be Decided if M Halts on the Empty Tape?

This is equivalent to, "Is the language $L_{2}=\left\{\right.$ " $\mathrm{M}^{\prime}$ : Turing machine M halts on the empty tape $\}$ recursive?"

$$
\begin{gathered}
\mathrm{L}_{1} \quad \mathrm{H}=\quad\{\mathrm{s}=\mathrm{M} \mathrm{M} " \mathrm{w} \mathrm{w} \text { : Turing machine } \mathrm{M} \text { halts on input string } \mathrm{w}\} \\
\Downarrow \\
\tau
\end{gathered}
$$

$$
\left(? \mathrm{M}_{2}\right) \quad \mathrm{L}_{2}=\quad\{\mathrm{s}=\text { "M": Turing machine } \mathrm{M} \text { halts on the empty tape }\}
$$

Let $\tau$ be the function that, from " M " and " w ", constructs " M " ", which operates as follows on an empty input tape:

1. Write w on the tape.
2. Operate as M would have.

If $M_{2}$ exists, then $M_{1}=M_{2}\left(M_{\tau}(s)\right)$ decides $L_{1}$.

## A Formal Reduction Proof

Prove that $L_{2}=\{\langle\mathbf{M}\rangle$ : Turing machine $M$ halts on the empty tape $\}$ is not recursive.
Proof that $L_{2}$ is not recursive via a reduction from $\mathrm{H}=\{\langle\mathrm{M}, \mathrm{w}\rangle$ : Turing machine M halts on input string w$\}$, a non-recursive language. Suppose that there exists a $T M, M_{2}$ that decides $L_{2}$. Construct a machine to decide $H$ as $M_{1}(\langle M, w\rangle)=M_{2}(\tau(\langle M, w\rangle)$. The $\tau$ function creates from $\langle M\rangle$ and $\langle w\rangle$ a new machine $M^{*} . M^{*}$ ignores its input and runs $M$ on $w$, halting exactly when $M$ halts on w.

- $\langle M, w\rangle \in H \Rightarrow M$ halts on $w \Rightarrow M^{*}$ always halts $\Rightarrow \varepsilon \in L\left(M^{*}\right) \Rightarrow\left\langle M^{*}\right\rangle \in L_{2} \Rightarrow M_{2}$ accepts $\Rightarrow M_{1}$ accepts.
- $\langle M, w\rangle \notin H \Rightarrow M$ does not halt on $w \Rightarrow \varepsilon \notin L\left(M^{*}\right) \Rightarrow\left\langle M^{*}\right\rangle \notin L_{2} \Rightarrow M_{2}$ rejects $\Rightarrow M_{1}$ rejects.

Thus, if there is a machine $\mathrm{M}_{2}$ that decides $\mathrm{L}_{2}$, we could use it to build a machine that decides H. Contradiction. $\therefore \mathrm{L}_{2}$ is not recursive.

## Important Elements in a Reduction Proof

- A clear declaration of the reduction "from" and "to" languages and what you're trying to prove with the reduction.
- A description of how a machine is being constructed for the "from" language based on an assumed machine for the "to" language and a recursive $\tau$ function.
- A description of the $\tau$ function's inputs and outputs. If $\tau$ is doing anything nontrivial, it is a good idea to argue that it is recursive.
- Note that machine diagrams are not necessary or even sufficient in these proofs. Use them as thought devices, where needed.
- Run through the logic that demonstrates how the "from" language is being decided by your reduction. You must do both accepting and rejecting cases.
- Declare that the reduction proves that your "to" language is not recursive.

## The Most Common Mistake: Doing the Reduction Backwards

The right way to use reduction to show that $L_{2}$ is not recursive:

1. Given that $\mathrm{L}_{1}$ is not recursive,
2. Reduce $L_{1}$ to $L_{2}$, i.e. show how to solve $L_{1}$ (the known one) in terms of $L_{2}$ (the unknown one)

Example: If there exists a machine $\mathrm{M}_{2}$ that solves $\mathrm{L}_{2}$, the problem of deciding whether a Turing machine halts on a blank tape, then we could do H (deciding whether M halts on w ) as follows:

1. Create $M^{*}$ from $M$ such that $M^{*}$, given a blank tape, first writes $w$ on its tape, then simulates the behavior of $M$.
2. Return $\mathrm{M}_{2}\left(\mathrm{"M}^{* ")}\right.$.

Doing it wrong by reducing $L_{2}$ (the unknown one to $L_{1}$ ): If there exists a machine $M_{1}$ that solves $H$, then we could build a machine that solves $L_{2}$ as follows:

1. Return $\left(\mathrm{M}_{1}\left(\right.\right.$ " $\left.\mathrm{M}^{2}, ~ " "\right)$ ).

## Why Backwards Doesn't Work

Suppose that we have proved that the following problem $L_{1}$ is unsolvable: Determine the number of days that have elapsed since the beginning of the universe.

Now consider the following problem $L_{2}$ : Determine the number of days that had elapsed between the beginning of the universe and the assassination of Abraham Lincoln.

Reduce $\mathrm{L}_{1}$ to $\mathrm{L}_{2}$ :
$\mathrm{L}_{1}=\mathrm{L}_{2}+($ now $-4 / 9 / 1865)$
$\mathrm{L}_{1}$
$\downarrow$
$\mathrm{~L}_{2}$
Reduce $\mathrm{L}_{2}$ to $\mathrm{L}_{1}$ :
$\mathrm{L}_{2}=\mathrm{L}_{1}-($ now $-4 / 9 / 1865)$

## Why Backwards Doesn't Work, Continued

$L_{1}=$ days since beginning of universe
$\mathrm{L}_{2}=$ elapsed days between the beginning of the universe and the assassination of Abraham Lincoln.
$\mathrm{L}_{3}=$ days between the assassination of Abraham Lincoln and now.
Considering $\mathrm{L}_{2}$ : $\quad \mathrm{L}_{1}$
Reduce $\mathrm{L}_{1}$ to $\mathrm{L}_{2}$ :
$\mathrm{L}_{1}=\mathrm{L}_{2}+($ now $-4 / 9 / 1865)$
Reduce $\mathrm{L}_{2}$ to $\mathrm{L}_{1}$ :
$L_{2}=L_{1}-($ now $-4 / 9 / 1865)$
$\begin{array}{lc}\text { Considering } \mathrm{L}_{3} \text { : } & \mathrm{L}_{1} \\ \text { Reduce } \mathrm{L}_{1} \text { to } \mathrm{L}_{3} \text { : } & \vee \\ \mathrm{L}_{1}=\text { oops } & \mathrm{L}_{3}\end{array}$
Reduce $\mathrm{L}_{3}$ to $\mathrm{L}_{1}$ :
$L_{3}=L_{1}-365-($ now $-4 / 9 / 1866)$

## Is There Any String on Which M Halts?

$\mathrm{L}_{1} \quad=\mathrm{H}=\quad\left\{\mathrm{s}=\right.$ " $\mathrm{M}^{\prime \prime} " \mathrm{w} ":$ Turing machine M halts on input string w$\}$
$\Downarrow \quad \tau$
$\left(? \mathrm{M}_{2}\right) \quad \mathrm{L}_{2}=\quad\{\mathrm{s}=" \mathrm{M} ":$ there exists a string on which Turing machine M halts $\}$
Let $\tau$ be the function that, from " M " and " w ", constructs " M *", which operates as follows:

1. $\mathrm{M}^{*}$ examines its input tape.
2. If it is equal to $w$, then it simulates $M$.
3. If not, it loops.

Clearly the only input on which $M^{*}$ has a chance of halting is $w$, which it does iff $M$ would halt on $w$.
If $M_{2}$ exists, then $M_{1}=M_{2}\left(M_{\tau}(s)\right)$ decides $L_{1}$.

## Does M Halt on All Inputs?

$$
\begin{gathered}
\mathrm{L}_{1}=\quad\{\mathrm{s}=" \mathrm{M} ": \text { Turing machine } \mathrm{M} \text { halts on the empty tape }\} \\
\Downarrow \\
\left(? \mathrm{M}_{2}\right) \quad \mathrm{L}_{2}=\quad\{\mathrm{s}=\text { "M": Turing machine } \mathrm{M} \text { halts on all inputs }\}
\end{gathered}
$$

Let $\tau$ be the function that, from " $\mathrm{M}^{\prime}$, constructs " $\mathrm{M}^{*}$ ", which operates as follows:

1. Erase the input tape.
2. Simulate M.

Clearly $\mathrm{M}^{*}$ either halts on all inputs or on none, since it ignores its input.
If $M_{2}$ exists, then $M_{1}=M_{2}\left(M_{\tau}(s)\right)$ decides $L_{1}$.

## Rice's Theorem

Theorem: No nontrivial property of the recursively enumerable languages is decidable.
Alternate statement: Let $\mathrm{P}: 2^{\Sigma^{*}} \rightarrow\{$ true, false $\}$ be a nontrivial property of the recursively enumerable languages. The language $\{$ "M": $\mathrm{P}(\mathrm{L}(\mathrm{M}))=$ True $\}$ is not recursive.

By "nontrivial" we mean a property that is not simply true for all languages or false for all languages.

## Examples:

- L contains only even length strings.
- L contains an odd number of strings.
- L contains all strings that start with "a".
- $L$ is infinite.
- L is regular.

## Note:

Rice's theorem applies to languages, not machines. So, for example, the following properties of machines are decidable:

- $\quad \mathbf{M}$ contains an even number of states
- $\quad \mathbf{M}$ has an odd number of symbols in its tape alphabet

Of course, we need a way to define a language. We'll use machines to do that, but the properties we'll deal with are properties of $\mathrm{L}(\mathrm{M})$, not of M itself.

## Proof of Rice's Theorem

Proof: Let P be any nontrivial property of the RE languages.
$\mathrm{L}_{1} \quad=\mathrm{H}=\{\mathrm{s}=" \mathrm{M} " \mathrm{w} ":$ Turing machine M halts on input string w$\}$

$$
\Downarrow \quad \tau
$$

$\left(? \mathrm{M}_{2}\right) \quad \mathrm{L}_{2}=$

$$
\{\mathrm{s}=\text { " } \mathrm{M} ": \mathrm{P}(\mathrm{~L}(\mathrm{M}))=\text { true }\}
$$

Either $P(\varnothing)=$ true or $P(\varnothing)=$ false. Assume it is false (a matching proof exists if it is true). Since $P$ is nontrivial, there is some language $L_{P}$ such that $P\left(L_{P}\right)$ is true. Let $M_{P}$ be some Turing machine that semidecides $L_{P}$.

Let $\tau$ construct " $\mathrm{M}^{*}$ ", which operates as follows:

1. Copy its input $y$ to another track for later.
2. Write w on its input tape and execute M on w .
3. If $M$ halts, put $y$ back on the tape and execute $M_{P}$.
4. If $\mathrm{M}_{\mathrm{P}}$ halts on y , accept.

Claim: If $\mathrm{M}_{2}$ exists, then $\mathrm{M}_{1}=\mathrm{M}_{2}\left(\mathrm{M}_{\tau}(\mathrm{s})\right)$ decides $\mathrm{L}_{1}$.

## Why?

Two cases to consider:

- $\quad " M^{\prime \prime} " w " \in H \Rightarrow M$ halts on $w \Rightarrow M^{*}$ will halt on all strings that are accepted by $M_{P} \Rightarrow L\left(M^{*}\right)=L\left(M_{P}\right)=L_{P} \Rightarrow P\left(L\left(M^{*}\right)\right)=$ $P\left(L_{P}\right)=$ true $\Rightarrow M_{2}$ decides $P$, so $M_{2}$ accepts " $\mathrm{M}^{*} " \Rightarrow \mathrm{M}_{1}$ accepts.
- $\quad " M^{\prime \prime} " w " \notin H \Rightarrow M$ doesn’t halt on $w \Rightarrow M^{*}$ will halt on nothing $\Rightarrow L\left(M^{*}\right)=\varnothing \Rightarrow P\left(L\left(M^{*}\right)\right)=P(\varnothing)=$ false $\Rightarrow M_{2}$ decides $P$, so $M_{2}$ rejects " $M^{*} " \Rightarrow M_{1}$ rejects.

## Using Rice's Theorem

Theorem: No nontrivial property of the recursively enumerable languages is decidable.

To use Rice's Theorem to show that a language $L$ is not recursive we must:

- Specify a language property, $\mathrm{P}(\mathrm{L})$
- Show that the domain of P is the set of recursively enumerable languages.
- Show that P is nontrivial:
$>P$ is true of at least one language
$>\mathrm{P}$ is false of at least one language

## Using Rice's Theorem: An Example

$\mathrm{L} \quad=\{\mathrm{s}=$ "M" : there exists a string on which Turing machine M halts $\}$.

$$
=\{s=" M ": L(M) \neq \varnothing\}
$$

- Specify a language property, $\mathrm{P}(\mathrm{L})$ :

$$
\mathrm{P}(\mathrm{~L})=\text { True iff } \mathrm{L} \neq \varnothing
$$

- Show that the domain of P is the set of recursively enumerable languages.

The domain of P is the set of languages semidecided by some TM. This is exactly the set of RE languages.

- Show that P is nontrivial:
$P$ is true of at least one language: $\mathrm{P}(\{\varepsilon\})=$ True
P is false of at least one language: $P(\varnothing)=$ False

## Inappropriate Uses of Rice's Theorem

## Example 1:

$\mathrm{L} \quad=\{\mathrm{s}=$ " M ": M writes a 1 within three moves $\}$.

- $\quad$ Specify a language property, $\mathrm{P}(\mathrm{L})$
$\mathrm{P}(\mathrm{M} ?)=$ True if M writes a 1 within three moves, False otherwise
- Show that the domain of P is the set of recursively enumerable languages. ??? The domain of P is the set of all TMs, not their languages

## Example 2:

$\mathrm{L} \quad=\{\mathrm{s}=$ "M1" "M2": L(M1) $=\mathrm{L}(\mathrm{M} 2)\}$.

- Specify a language property. $\mathrm{P}(\mathrm{L})$
$\mathrm{P}(\mathrm{M} 1$ ? , M 2 ? $)=$ True if $\mathrm{L}(\mathrm{M} 1)=\mathrm{L}(\mathrm{M} 2)$
False otherwise
- Show that the domain of P is the set of recursively enumerable languages.
??? The domain of P is $\mathrm{RE} \times \mathrm{RE}$

## Given a Turing Machine $\mathbf{M}$, is $\mathbf{L}(\mathbf{M})$ Regular (or Context Free or Recursive)?

Is this problem decidable?
No, by Rice's Theorem, since being regular (or context free or recursive) is a nontrivial property of the recursively enumerable languages.

We can also show this directly (via the same technique we used to prove the more general claim contained in Rice's Theorem):

## Given a Turing Machine $\mathbf{M}$, is $\mathbf{L}(\mathbf{M})$ Regular (or Context Free or Recursive)?

$$
\begin{aligned}
& L_{1}=H=\{s=" M " \text { "w" : Turing machine } M \text { halts on input string } w\} \\
& \Downarrow \\
&\left(? M_{2}\right) \quad L_{2}=\quad\{s=" M ": L(M) \text { is regular }\}
\end{aligned}
$$

Let $\tau$ be the function that, from " $M$ " and " $w$ ", constructs " $M^{*}$ ", whose own input is a string $\mathrm{t}=\mathrm{M} \mathrm{M}_{*}$ " " $\mathrm{w} *$ "
$\mathrm{M}^{*}\left(\mathrm{M}_{*}{ }^{*}\right.$ " $\mathrm{w}_{*}$ ") operates as follows:

1. Copy its input to another track for later.
2. Write w on its input tape and execute M on w .
3. If M halts, invoke U on " $\mathrm{M}_{*}$ " " w "".
4. If $U$ halts, halt and accept.

If $M_{2}$ exists, then $\neg \mathrm{M}_{2}\left(\mathrm{M}^{*}(\mathrm{~s})\right)$ decides $L_{1}(\mathrm{H})$.

## Why?

If M does not halt on w , then $\mathrm{M}^{*}$ accepts $\varnothing$ (which is regular).
If M does halt on w , then $\mathrm{M}^{*}$ accepts H (which is not regular).

## Undecidable Problems About Unrestricted Grammars

- Given a grammar $G$ and a string $w$, is $w \in L(G)$ ?
- Given a grammar G , is $\varepsilon \in \mathrm{L}(\mathrm{G})$ ?
- Given two grammars $\mathrm{G}_{1}$ and $\mathrm{G}_{2}$, is $\mathrm{L}\left(\mathrm{G}_{1}\right)=\mathrm{L}\left(\mathrm{G}_{2}\right)$ ?
- Given a grammar G , is $\mathrm{L}(\mathrm{G})=\varnothing$ ?

Given a Grammar G and a String $\mathbf{w}$, Is $w \in \mathbf{L}(\mathbf{G})$ ?
$\mathrm{L}_{1} \quad=\mathrm{H}=\{\mathrm{s}=" \mathrm{M} " \mathrm{w}$ ": Turing machine M halts on input string w$\}$
$\Downarrow \quad \tau$
$\left(? \mathrm{M}_{2}\right)$

$$
\mathrm{L}_{2}=
$$

$$
\{\mathrm{s}=\text { "G" "w" : w } \in \mathrm{L}(\mathrm{G})\}
$$

Let $\tau$ be the construction that builds a grammar G for the language L that is semidecided by M . Thus $w \in L(G)$ iff $M(w)$ halts.

Then $\quad \tau(" M "$ "w") $=$ "G" "w"
If $M_{2}$ exists, then $M_{1}=M_{2}\left(M_{\tau}(s)\right)$ decides $L_{1}$.

## Undecidable Problems About Context-Free Grammars

- Given a context-free grammar G , is $\mathrm{L}(\mathrm{G})=\Sigma^{*}$ ?
- Given two context-free grammars $\mathrm{G}_{1}$ and $\mathrm{G}_{2}$, is $\mathrm{L}\left(\mathrm{G}_{1}\right)=\mathrm{L}\left(\mathrm{G}_{2}\right)$ ?
- Given two context-free grammars $\mathrm{G}_{1}$ and $\mathrm{G}_{2}$, is $\mathrm{L}\left(\mathrm{G}_{1}\right) \cap \mathrm{L}\left(\mathrm{G}_{2}\right)=\varnothing$ ?
- Is context-free grammar, G ambiguous?
- Given two pushdown automata $\mathrm{M}_{1}$ and $\mathrm{M}_{2}$, do they accept precisely the same language?
- Given a pushdown automaton M, find an equivalent pushdown automaton with as few states as possible.

## Given Two Context-Free Grammars $\mathbf{G}_{\mathbf{1}}$ and $\mathbf{G}_{\mathbf{2}}$, Is $\mathbf{L}\left(\mathbf{G}_{\mathbf{1}}\right)=\mathbf{L}\left(\mathbf{G}_{\mathbf{2}}\right)$ ?

$$
\begin{array}{cc}
\mathrm{L}_{1}= & \left\{\mathrm{s}=" \mathrm{G}^{\prime} \text { a CFG G and } \mathrm{L}(\mathrm{G})=\Sigma^{*}\right\} \\
& \Downarrow \\
\left(? \mathrm{M}_{2}\right) \quad & \tau \\
& \mathrm{L}_{2}=\quad\left\{\mathrm{s}=" \mathrm{G}_{1} " " \mathrm{G}_{2} ": \mathrm{G}_{1} \text { and } \mathrm{G}_{2} \text { are CFGs and } \mathrm{L}\left(\mathrm{G}_{1}\right)=\mathrm{L}\left(\mathrm{G}_{2}\right)\right\}
\end{array}
$$

Let $\tau$ append the description of a context free grammar $\mathrm{G}_{\Sigma^{*}}$ that generates $\Sigma^{*}$.
Then, $\tau\left(\right.$ ("G") = "G" "G $\mathrm{G}_{\Sigma *}$ "
If $\mathrm{M}_{2}$ exists, then $\mathrm{M}_{1}=\mathrm{M}_{2}\left(\mathrm{M}_{\tau}(\mathrm{s})\right)$ decides $\mathrm{L}_{1}$.

## Non-RE Languages

There are an uncountable number of non-RE languages, but only a countably infinite number of TM's (hence RE languages). $\therefore$ The class of non-RE languages is much bigger than that of RE languages!

Intuition: Non-RE languages usually involve either infinite search or knowing a TM will infinite loop to accept a string.
$\{\langle\mathrm{M}\rangle$ : M is a TM that does not halt on the empty tape $\}$
$\left\{\langle\mathrm{M}\rangle: \mathrm{M}\right.$ is a TM and $\left.\mathrm{L}(\mathrm{M})=\Sigma^{*}\right\}$
$\{\langle\mathrm{M}\rangle$ : M is a TM and there does not exist a string on which M halts $\}$

## Proving Languages are not RE

- Diagonalization
- Complement RE, not recursive
- Reduction from a non-RE language
- Rice's theorem for non-RE languages (not covered)

## Diagonalization

$\mathrm{L}=\{\langle\mathrm{M}\rangle: \mathrm{M}$ is a TM and $\mathrm{M}(\langle\mathrm{M}\rangle)$ does not halt $\}$ is not RE
Suppose L is RE. There is a TM M* that semidecides L . Is $\left\langle\mathbf{M}^{*}\right\rangle$ in L ?

- If it is, then $\mathbf{M}^{*}\left(\left\langle\mathbf{M}^{*}\right\rangle\right)$ halts (by the definition of $\mathbf{M}^{*}$ as a semideciding machine for L )
- But, by the definition of $L$, if $\left\langle\mathbf{M}^{*}\right\rangle \in \mathrm{L}$, then $\mathrm{M}^{*}\left(\left\langle\mathbf{M}^{*}\right\rangle\right)$ does not halt.

Contradiction. So L is not RE.
(This is a very "bare-bones" diagonalization proof.)
Diagonalization can only be easily applied to a few non-RE languages.

## Complement of an RE, but not Recursive Language

Example: $\overline{\mathrm{H}}=\{\langle\mathrm{M}, \mathrm{w}\rangle$ : M does not accept w$\}$
Consider $\mathrm{H}=\{\langle\mathrm{M}, \mathrm{w}\rangle$ : M is a TM that accepts w$\}$ :

- H is RE—it is semidecided by U, the Universal Turing Machine.
- H is not recursive-it is equivalent to the halting problem, which is undecidable.

From the theorem, $\overline{\mathrm{H}}$ is not RE.

## Reductions and RE Languages

Theorem: If there is a reduction from $L_{1}$ to $L_{2}$ and $L_{2}$ is $R E$, then $L_{1}$ is RE.

Theorem: If there is a reduction from $L_{1}$ to $L_{2}$ and $L_{1}$ is not $R E$, then $L_{2}$ is not RE.

## Reduction from a known non-RE Language

Using a reduction from a non-RE language:

$$
\begin{gathered}
\mathrm{L}_{1}=\overline{\mathrm{H}}=\{\langle\mathrm{M}, \mathrm{w}\rangle \text { : Turing machine } \mathrm{M} \text { does not halt on input string } \mathrm{w}\} \\
\Downarrow \tau
\end{gathered}
$$

$\left(? \mathrm{M}_{2}\right) \quad \mathrm{L}_{2}=\{\langle\mathrm{M}\rangle$ : there does not exist a string on which Turing machine M halts $\}$
Let $\tau$ be the function that, from $\langle\mathbf{M}\rangle$ and $\langle\mathrm{w}\rangle$, constructs $\left\langle\mathbf{M}^{*}\right\rangle$, which operates as follows:

1. Erase the input tape ( $\mathrm{M}^{*}$ ignores its input).
2. Write w on the tape
3. Run M on w.

$\langle\mathrm{M}, \mathrm{w}\rangle \in \overline{\mathrm{H}} \Rightarrow \mathrm{M}$ does not halt on $\mathrm{w} \Rightarrow \mathrm{M}^{*}$ does not halt on any input $\Rightarrow \mathrm{M}^{*}$ halts on nothing $\Rightarrow \mathrm{M}_{2}$ accepts (halts).
$\langle\mathrm{M}, \mathrm{w}\rangle \notin \overline{\mathrm{H}} \Rightarrow \mathrm{M}$ halts on $\mathrm{w} \Rightarrow \mathrm{M}^{*}$ halts on everything $\Rightarrow \mathrm{M}_{2}$ loops.

If $\mathrm{M}_{2}$ exists, then $\mathrm{M}_{1}(\langle\mathrm{M}, \mathrm{w}\rangle)=\mathrm{M}_{2}\left(\mathrm{M}_{\tau}(\langle\mathrm{M}, \mathrm{w}\rangle)\right)$ and $\mathrm{M}_{1}$ semidecides $\mathrm{L}_{1}$. Contradiction. $\mathrm{L}_{1}$ is not RE. $\therefore \mathrm{L}_{2}$ is not RE.
Semidecidable
Enumerable
Unrestricted grammar
Decision procedure
Lexicicographically enumerable
Complement is recursively enumer.
CF grammar

Closure
Closure

## Introduction to Complexity Theory

Read K \& S Chapter 6.

Most computational problems you will face your life are solvable (decidable). We have yet to address whether a problem is "easy" or "hard". Complexity theory tries to answer this question.

Recall that a computational problem can be recast as a language recognition problem.
Some "easy" problems:

- Pattern matching
- Parsing
- Database operations (select, join, etc.)
- Sorting

Some "hard" problems:

- Traveling salesman problem
- Boolean satisfiability
- Knapsack problem
- Optimal flight scheduling
"Hard" problems usually involve the examination of a large search space.

## Big-O Notation

- Gives a quick-and-dirty measure of function size
- Used for time and space metrics

A function $\mathrm{f}(\mathrm{n})$ is $\mathrm{O}(\mathrm{g}(\mathrm{n}))$ whenever there exists a constant c , such that $|\mathrm{f}(\mathrm{n})| \leq \mathrm{c} \cdot|\mathrm{g}(\mathrm{n})|$ for all $\mathrm{n} \geq 0$.
(We are usually most interested in the "smallest" and "simplest" function, g.)
Examples:

$$
\begin{aligned}
& 2 n^{3}+3 n^{2} \cdot \log (n)+75 n^{2}+7 n+2000 \text { is } \underline{O\left(n^{3}\right)} \\
& 75 \cdot 2^{n}+200 n^{5}+10000 \text { is } \underline{O\left(2^{n}\right)}
\end{aligned}
$$

A function $f(n)$ is polynomial if $f(n)$ is $O(p(n))$ for some polynomial function $p$.
If a function $\mathrm{f}(\mathrm{n})$ is not polynomial, it is considered to be exponential, whether or not it is O of some exponential function (e.g. $\mathrm{n}^{\log \mathrm{n}}$ ).

In the above two examples, the first is polynomial and the second is exponential.

## Comparison of Time Complexities

Speed of various time complexities for different values of n , taken to be a measure of problem size. (Assumes 1 step per microsecond.)

| $\mathbf{f ( n ) \backslash \mathbf { n }}$ | $\mathbf{1 0}$ | $\mathbf{2 0}$ | $\mathbf{3 0}$ | $\mathbf{4 0}$ | $\mathbf{5 0}$ | $\mathbf{6 0}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{n}$ | .00001 sec. | .00002 sec. | .00003 sec. | .00004 sec. | .00005 sec. | .00006 sec. |
| $\mathbf{n}^{2}$ | .0001 sec. | .0004 sec. | .0009 sec. | .0016 sec. | .0025 sec. | .0036 sec. |
| $\mathbf{n}^{\mathbf{3}}$ | .001 sec. | .008 sec. | .027 sec. | .064 sec. | .125 sec. | .216 sec. |
| $\mathbf{n}^{5}$ | .1 sec. | 3.2 sec. | 24.3 sec. | 1.7 min. | 5.2 min. | 13.0 min. |
| $\mathbf{2}^{\mathbf{n}}$ | .001 sec. | 1.0 sec. | 17.9 min. | 12.7 days | 35.7 yr. | 366 cent. |
| $\mathbf{3}^{\mathbf{n}}$ | .059 sec. | 58 min. | 6.5 yr. | 3855 cent. | $2 \times 10^{8}$ cent. | $1.3 \times 10^{13}$ cent. |

Faster computers don't really help. Even taking into account Moore's Law, algorithms with exponential time complexity are considered intractable. $\therefore$ Polynomial time complexities are strongly desired.

## Polynomial Land

If $f_{1}(n)$ and $f_{2}(n)$ are polynomials, then so are:

- $f_{1}(n)+f_{2}(n)$
- $f_{1}(\mathrm{n}) \cdot \mathrm{f}_{2}(\mathrm{n})$
- $\quad \mathrm{f}_{1}\left(\mathrm{f}_{2}(\mathrm{n})\right)$

This means that we can sequence and compose polynomial-time algorithms with the resulting algorithms remaining polynomialtime.

## Computational Model

For formally describing the time (and space) complexities of algorithms, we will use our old friend, the deciding TM (decision procedure).

There are two parts:

- The problem to be solved must be translated into an equivalent language recognition problem.
- A TM to solve the language recognition problem takes an encoded instance of the problem (of size $n$ symbols) as input and decides the instance in at most $T_{M}(n)$ steps.

We will classify the time complexity of an algorithm (TM) to solve it by its big-O bound on $T_{M}(n)$.
We are most interested in polynomial time complexity algorithms for various types of problems.

## Encoding a Problem

Traveling Salesman Problem: Given a set of cities and the distances between them, what is the minimum distance tour a salesman can make that covers all cities and returns him to his starting city?

Stated as a decision question over graphs: Given a graph $\mathrm{G}=(\mathrm{V}, \mathrm{E})$, a positive distance function for each edge d : $\mathrm{E} \rightarrow \mathrm{N}+$, and a bound B , is there a circuit that covers all V where $\Sigma^{\mathrm{d}}(\mathrm{e}) \leq \mathrm{B}$ ? (Here a minimization problem was turned into a bound problem.)

A possible encoding the problem:

- Give $|\mathrm{V}|$ as an integer.
- Give B as an integer.
- Enumerate all ( $\left.\mathrm{v}_{1}, \mathrm{v}_{2}, \mathrm{~d}\right)$ as a list of triplets of integers (this gives both E and d ).
- All integers are expressed as Boolean numbers.
- Separate these entries with commas.

Note that the sizes of most "reasonable" problem encodings are polynomially related.

## What about Turing Machine Extensions?

Most TM extensions are can be simulated by a standard TM in a time polynomially related to the time of the extended machine.

- $\quad \mathrm{k}$-tape TM can be simulated in $\mathrm{O}\left(\mathrm{T}^{2}(\mathrm{n})\right)$
- Random Access Machine can be simulated in $\mathrm{O}\left(\mathrm{T}^{3}(\mathrm{n})\right)$
(Real programming languages can be polynomially related to the RAM.)
BUT... The nondeterminism TM extension is different.
A nondeterministic TM can be simulated by a standard TM in $\mathrm{O}\left(2^{p(n)}\right)$ for some polynomial $p(n)$.
Some faster simulation method might be possible, but we don't know it.
Recall that a nondeterministic TM can use a "guess and test" approach, which is computationally efficient at the expense of many parallel instances.

## The Class $P$

$\mathbf{P}=\{\mathrm{L}:$ there is a polynomial-time deterministic $\mathrm{TM}, \mathrm{M}$ that decides L$\}$
Roughly speaking, P is the class of problems that can be solved by deterministic algorithms in a time that is polynomially related to the size of the respective problem instance.

The way the problem is encoded or the computational abilities of the machine carrying out the algorithm are not very important.
Example: Given an integer $n$, is there a positive integer $m$, such that $n=4 m$ ?
Problems in P are considered tractable or "easy".

## The Class NP

$\mathbf{N P}=\{\mathrm{L}:$ there is a polynomial time nondeterministic $\mathrm{TM}, \mathrm{M}$ that decides L$\}$
Roughly speaking, NP is the class of problems that can be solved by nondeterministic algorithms in a time that is polynomially related to the size of the respective problem instance.

Many problems in NP are considered "intractable" or "hard".
Examples:

- Traveling salesman problem: Given a graph $G=(V, E)$, a positive distance function for each edge $d: E \rightarrow N+$, and a bound $B$, is there a circuit that covers all $V$ where $\Sigma(\mathrm{e}) \leq \mathrm{B}$ ?
- Subgraph isomorphism problem: Given two graphs $G_{1}$ and $G_{2}$, does $G_{1}$ contain a subgraph isomorphic to $G_{2}$ ?

## The Relationship of P and NP

We're considering only solvable (decidable) problems.
Clearly $\mathrm{P} \subseteq \mathrm{NP}$.
$P$ is closed under complement.
NP probably isn't closed under complement. Why?
Whether $P=$ NP is considered computer science's greatest unsolved problem.

## Why NP is so Interesting

- To date, nearly all decidable problems with polynomial bounds on the size of the solution are in this class.
- Most NP problems have simple nondeterministic solutions.
- The hardest problems in NP have exponential deterministic time complexities.
- Nondeterminism doesn't influence decidability, so maybe it shouldn't have a big impact on complexity.
- Showing that $\mathrm{P}=\mathrm{NP}$ would dramatically change the computational power of our algorithms.

## Stephen Cook's Contribution (1971)

- Emphasized the importance of polynomial time reducibility.
- Pointed out the importance of NP.
- Showed that the Boolean Satisfiability (SAT) problem has the property that every other NP problem can be polynomially reduced to it. Thus, SAT can be considered the hardest problem in NP.
- Suggested that other NP problems may also be among the "hardest problems in NP".

This "hardest problems in NP" class is called the class of "NP-complete" problems.
Further, if any of these NP-complete problems can be solved in deterministic polynomial time, they all can and, by implication, $\mathrm{P}=\mathrm{NP}$.

Nearly all of complexity theory relies on the assumption that $\mathrm{P} \neq \mathrm{NP}$.

## Polynomial Time Reducibility

A language $L_{1}$ is polynomial time reducible to $L_{2}$ if there is a polynomial-time recursive function $\tau$ such that $\forall x \in L_{1}$ iff $\tau(x) \in$ $\mathrm{L}_{2}$.

If $L_{1}$ is polynomial time reducible to $L_{2}$, we say $L_{1}$ reduces to $L_{2}$ ("polynomial time" is assumed) and we write it as $L_{1} \propto L_{2}$.
Lemma: If $\mathrm{L}_{1} \propto \mathrm{~L}_{2}$, then $\left(\mathrm{L}_{2} \in \mathrm{P}\right) \Rightarrow\left(\mathrm{L}_{1} \in \mathrm{P}\right)$. And conversely, $\left(\mathrm{L}_{1} \notin \mathrm{P}\right) \Rightarrow\left(\mathrm{L}_{2} \notin \mathrm{P}\right)$.
Lemma: If $\mathrm{L}_{1} \propto \mathrm{~L}_{2}$ and $\mathrm{L}_{2} \propto \mathrm{~L}_{3}$ then $\mathrm{L}_{1} \propto \mathrm{~L}_{3}$.
$\mathrm{L}_{1}$ and $\mathrm{L}_{2}$ are polynomially equivalent whenever both $\mathrm{L}_{1} \propto \mathrm{~L}_{2}$ and $\mathrm{L}_{2} \propto \mathrm{~L}_{1}$.
Polynomially equivalent languages form an equivalence class. The partitions of this equivalence class are related by the partial order $\propto$.
P is the "least" element in this partial order.
What is the "maximal" element in the partial order?

## The Class NP-Complete

A language L is $N P$-complete if $\mathrm{L} \in \mathrm{NP}$ and for all other languages $\mathrm{L}^{\prime} \in \mathrm{NP}, \mathrm{L}^{\prime} \propto \mathrm{L}$.
NP-Complete problems are the "hardest" problems in NP.
Lemma: If $L_{1}$ and $L_{2}$ belong to NP, $L_{1}$ is NP-complete and $L_{1} \propto L_{2}$, then $L_{2}$ is NP-complete.
Thus to prove a language $L_{2}$ is NP-complete, you must do the following:

1. Show that $L_{2} \in N P$.
2. Select a known NP-complete language $\mathrm{L}_{1}$.
3. Construct a reduction $\tau$ from $L_{1}$ to $L_{2}$.
4. Show that $\tau$ is polynomial-time function.

How do we get started? Is there a language that is NP-complete?

## Boolean Satisfiability (SAT)

Given a set of Boolean variables $U=\left\{u_{1}, u_{2}, \ldots, u_{m}\right\}$ and a Boolean expression in conjunctive normal form (conjunctions of clauses-disjunctions of variables or their negatives), is there a truth assignment to $U$ that makes the Boolean expression true (satisfies the expression)?

Note: All Boolean expressions can be converted to conjunctive normal form.
Example: $\left(\mathrm{x}_{1} \vee \neg \mathrm{x}_{2} \vee \mathrm{x}_{3}\right) \wedge\left(\neg \mathrm{x}_{3} \vee \mathrm{x}_{4} \vee \neg \mathrm{x}_{2}\right)$
Cook's Theorem: SAT is NP-complete.

1. Clearly SAT $\in$ NP.
2. The proof constructs a complex Boolean expression that satisfied exactly when a NDTM accepts an input string $x$ where $|\mathrm{w}|=\mathrm{n}$. Because the NDTM is in NP, its running time is $\mathrm{O}(\mathrm{p}(\mathrm{n})$ ). The number of variables is polynomially related to $\mathrm{p}(\mathrm{n})$.

## SAT is $N P$-complete because SAT $\in$ NP and for all other languages $L^{\prime} \in \mathbb{N}, L^{\prime} \propto$ SAT.

## Reduction Roadmap

The early NP-complete reductions took this structure. Each phrase represents a problem. The arrow represents a reduction from one problem to another.

Today, thousands of diverse problems have been shown to be NP-complete.
Let's now look at these problems.

## 3SAT (3-satisfiability)

Boolean satisfiability where each clause has exactly 3 terms.

## 3DM (3-Dimensional Matching)

Consider a set $\mathrm{M} \subseteq \mathrm{X} \times \mathrm{Y} \times \mathrm{Z}$ of disjoint sets, $\mathrm{X}, \mathrm{Y}, \& \mathrm{Z}$, such that $|\mathrm{X}|=|\mathrm{Y}|=|\mathrm{Z}|=\mathrm{q}$. Does there exist a matching, a subset $M^{\prime} \subseteq M$ such that $\left|M^{\prime}\right|=q$ and $M^{\prime}$ partitions $X, Y$, and $Z$ ?

This is a generalization of the marriage problem, which has two sets men \& women and a relation describing acceptable marriages. Is there a pairing that marries everyone acceptably?

The marriage problem is in P , but this " 3 -sex version" of the problem is NP-complete.

## PARTITION

Given a set A and a positive integer size, $\mathrm{s}(\mathrm{a}) \in \mathrm{N}^{+}$, for each element, $\mathrm{a} \in \mathrm{A}$. Is there a subset $\mathrm{A}^{\prime} \subseteq \mathrm{A}$ such that

$$
\sum_{\mathrm{a} \in \mathrm{~A}^{\prime}}^{\sum \mathrm{s}(\mathrm{a})=} \sum_{\mathrm{a} \in \mathrm{~A}-\mathrm{A}^{\prime}} \mathrm{s}(\mathrm{a}) ?
$$

## VC (Vertex Cover)

Given a graph $G=(V, E)$ and an integer $K$, such that $0<K \leq|V|$, is there a vertex cover of size $K$ or less for $G$, that is, a subset $\mathrm{V}^{\prime} \subseteq \mathrm{V}$ such that $\left|\mathrm{V}^{\prime}\right| \leq \mathrm{K}$ and for each edge, $(\mathrm{u}, \mathrm{v}) \in \mathrm{E}$, at least one of u and v belongs to $\mathrm{V}^{\prime}$ ?

## CLIQUE

Given a graph $\mathrm{G}=(\mathrm{V}, \mathrm{E})$ and an integer J , such that $0<\mathrm{J} \leq|\mathrm{V}|$, does G contain a clique of size J or more, that is a subset $\mathrm{V}^{\prime} \subseteq \mathrm{V}$ such that $\left|\mathrm{V}^{\prime}\right| \geq \mathrm{J}$ and every two vertices in $\mathrm{V}^{\prime}$ are joined by an edge in E ?

## HC (Hamiltononian Circuit)

Given a graph $\mathrm{G}=(\mathrm{V}, \mathrm{E})$, does there exist a Hamiltonian circuit, that is an ordering $\left\langle\mathrm{v}_{1}, \mathrm{v}_{2}, \ldots, \mathrm{v}_{\mathrm{n}}\right\rangle$ of all V such that $\left(\mathrm{v}_{|\mathrm{V}|}, \mathrm{v}_{1}\right) \in \mathrm{E}$ and $\left(\mathrm{v}_{\mathrm{i}}, \mathrm{v}_{\mathrm{i}+1}\right) \in \mathrm{E}$ for all $\mathrm{i}, 1 \leq \mathrm{i}<|\mathrm{V}|$ ?

## Traveling Salesman Prob. is NP-complete

Given a graph $G=(V, E)$, a positive distance function for each edge $d$ : $\mathrm{E} \rightarrow \mathrm{N}+$, and a bound B , is there a circuit that covers all V where $\boldsymbol{\Sigma}^{\mathrm{d}}(\mathrm{e}) \leq \mathrm{B}$ ?

To prove a language TSP is NP-complete, you must do the following:

1. Show that TSP $\in$ NP.
2. Select a known NP-complete language $\mathrm{L}_{1}$.
3. Construct a reduction $\tau$ from $\mathrm{L}_{1}$ to TSP.
4. Show that $\tau$ is polynomial-time function.
$\mathbf{T S P} \in \mathbf{N P}:$ Guess a set of roads. Verify that the roads form a tour that hits all cities. Answer "yes" if the guess is a tour and the sum of the distances is $\leq \mathrm{B}$.

Reduction from HC: Answer the Hamiltonian circuit question on $G=(V, E)$ by constructing a complete graph where "roads" have distance 1 if the edge is in E and 2 otherwise. Pose the TSP problem, is there a tour of length $\leq|\mathrm{V}|$ ?

## Notes on NP-complete Proofs

The more NP-complete problems are known, the easier it is to find a NP-complete problem to reduce from.
Most reductions are somewhat complex.
It is sufficient to show that a restricted version of the problem is NP-complete.

## More Theory

NP has a rich structure that includes more than just P and NP-complete. This structure is studied in later courses on the theory of computation.

The set of recursive problems outside of NP (and including NP-complete) are called $N P$-hard. There is a proof technique to show that such problems are at least as hard as NP-complete problems.

Space complexity addresses how much tape does a TM use in deciding a language. There is a rich set of theories surrounding space complexity.

## Dealing with NP-completeness

You will likely run into NP-complete problems in your career. For example, most optimization problems are NP-complete.
Some techniques for dealing with intractable problems:

- Recognize when there is a tractable special case of the general problem.
- Use other techniques to limit the search space.
- For optimization problems, seek a near-optimal solution.

The field of linear optimization springs out of the latter approach. Some linear optimization solutions can be proven to be "near" optimal.

A branch of complexity theory deals with solving problems within some error bound or probability.
