Viewing III: Camera, Models, Projections and their Relations

Order of Matrices in a graphics pipeline

- 1. ModelView : modeling transformations applied to positiion and orient objects and camera
- 2. Projection: scales/translates/shears each vertex of object so they lie inside a standard cube with each coordinate dimension being -1 to 1
- 3. ViewPort: maps standard cube into a rectangle screen coordinates with depth normalized from 0 to 1 (depth buffer).

OpenGL's default coordinate system

Why is the viewing direction towards the -z axis ?

Projections

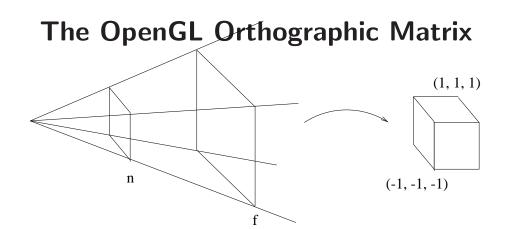

- Mapping from 3 dimensional space to 2 dimensional subspace
- Range of any projection $\mathcal{P}: R^3 \to R^2$ called a *projection plane*
- \mathcal{P} maps lines to points
- The image of any point p under ${\cal P}$ is the intersection of a *projection line* through p with the projection plane.

Taxonomy

- Parallel
 - orthographic
 - oblique
- Perspective
 - 1-pt
 - 2-pt
 - 3-pt

Parallel Projections

- All projection lines are parallel.
- An *orthographic projection* has projection lines orthogonal to projection plane.
- Otherwise a parallel projection is an *oblique projection*
- Particularly interesting oblique projections are the *cabinet projection* and the *cavalier projection*.

- The visible volume in world space is known as the *viewing volume*.
- Specify with the call glOrtho(l, r, b, t, n, f)
- In OpenGL, the window is in the *near* plane
- l and r are u-coordinates of left and right window boundaries in the near plane
- b and t are v-coordinates of bottom and top window boundaries in the near plane
- *n* and *f* are *positive distances* from the eye along the viewing ray to the near and far planes
- The left and right clipping planes are x = -1 and x = 1
- The bottom and top clipping planes are y = -1 and y = 1
- The near and far clipping planes are z = -1 and z = 1

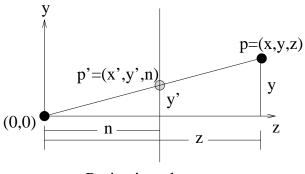

$$\begin{bmatrix} x'\\y'\\z'\\1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0\\0 & 1 & 0 & 0\\0 & 0 & 0 & 0\\0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x\\y\\z\\1 \end{bmatrix}$$

Perspective Projection

- All projection lines pass through the *center of projection* (eyepoint).
- Therefore also called *central projection*
- This is *not* affine, but rather a *projective transformation*, (also discussed in previous lecture).
- Differences in Perspective
 - 1-pt
 - 2-pt
 - 3-pt

Perspective Transform in Eye Coordinates

- Given a point \mathbf{p} , find its projection $\mathcal{P}(\mathbf{p})$
- Convenient to do this in *eye coordinates*, with center of projection at origin and z = n projection plane
- Note that eye coordinates are left-handed

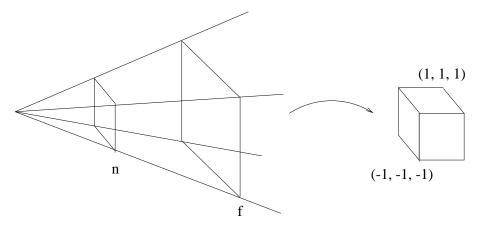

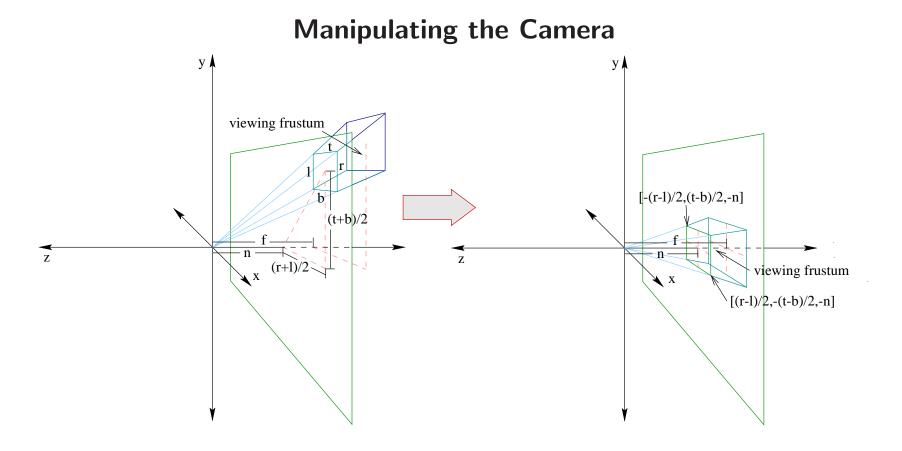

- Due to similar triangles $\mathcal{P}(\mathbf{p}) = (nx/z, ny/z, n)$
- For any other point ${\bf q}=(kx,ky,kz), k\neq 0$ on same projection line ${\cal P}({\bf q})=(nx/z,ny/z,n)$
- If we have surfaces, we need to know which ones occlude others from the eye position
- This projection loses all z information, so we cannot do occlusion testing after projection

The OpenGL Perspective Matrix

- The visible volume in world space is known as the *viewing pyramid* or *frustum*.
- Specify with the call $\mathbf{glFrustum}(l, r, b, t, n, f)$
- In OpenGL, the window is in the *near* plane
- l and r are u-coordinates of left and right window boundaries in the near plane
- b and t are v-coordinates of bottom and top window boundaries in the near plane
- n and f are *positive distances* from the eye along the viewing ray to the near and far planes
- Maps the left and right clipping planes to x = -1 and x = 1
- Maps the bottom and top clipping planes to y = -1 and y = 1
- Maps the near and far clipping planes to z = -1 and z = 1

- After applying the modelview matrix, we are looking down the -z axis.
- We need to move the ray from the origin through the window center onto the -z axis.
- Rotation won't do since the window wouldn't be orthogonal to the z axis.
- Translation won't do since we need to keep the eye at the origin.

The University of Texas at Austin

GRAPHICS – SPRING 2013 (LECTURE 8)

DEPARTMENT OF COMPUTER SCIENCES

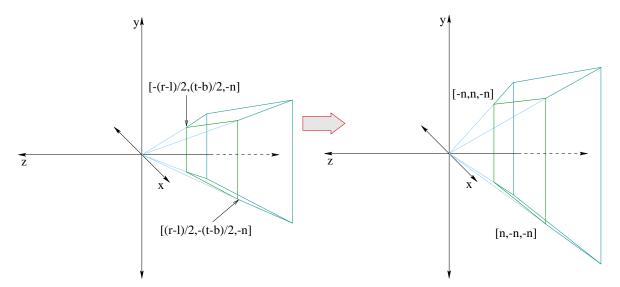

- We need differential translation as a function of z, i.e. shear.
- When z = -n, δx should be $-\frac{r+l}{2n}$ and δy should be $-\frac{t+b}{2n}$, so we get

$$x' = x + \frac{r+l}{2n}z$$
$$y' = y + \frac{t+b}{2n}z$$
$$z' = z$$

$$\begin{bmatrix} x'\\y'\\z'\\1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & \frac{r+l}{2n} & 0\\0 & 1 & \frac{t+b}{2n} & 0\\0 & 0 & 1 & 0\\0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x\\y\\z\\1 \end{bmatrix}$$

Adjusting the Clipping Boundaries

- For ease of clipping, we want the oblique clipping planes to have equations $x = \pm z$ and $y = \pm z$.
- This will make the window square, with boundaries l = b = -n and r = t = n.
- This requires a scale to make the window this size.

Thus the mapping is

$$x' = \frac{2nx}{r-l}$$
$$y' = \frac{2ny}{t-b}$$
$$z' = z$$

or in matrix form:

$$\begin{bmatrix} x'\\y'\\z'\\1 \end{bmatrix} = \begin{bmatrix} \frac{2n}{r-l} & 0 & 0 & 0\\ 0 & \frac{2n}{t-b} & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x\\y\\z\\1 \end{bmatrix}$$

Complete OpenGL Perspective Matrix

Combining the three steps given above, the complete OpenGL perspective matrix generated by the call $\mathbf{glFrustum}(l,r,b,t,n,f)$

$$= \begin{bmatrix} \frac{2n}{r-l} & 0 & \frac{r+l}{r-l} & 0\\ 0 & \frac{2n}{t-b} & \frac{t+b}{t-b} & 0\\ 0 & 0 & \frac{-(f+n)}{f-n} & \frac{-2fn}{f-n}\\ 0 & 0 & -1 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & \frac{r+l}{2n} & 0\\ 0 & \frac{2n}{t-b} & 0 & 0\\ 0 & \frac{2n}{t-b} & 0 & 0\\ 0 & \frac{2n}{t-b} & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & \frac{r+l}{2n} & 0\\ 0 & 1 & \frac{t+b}{2n} & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{bmatrix}$$

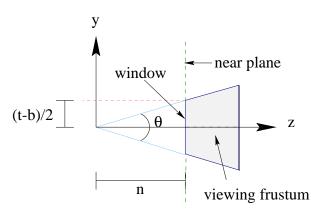

Complete OpenGL Orthographic Matrix

Combining the three steps given above, the complete OpenGL orthographic matrix generated by the call ${\bf glOrtho}(l,r,b,t,n,f)$

$$= \begin{bmatrix} \frac{2}{r-l} & 0 & 0 & -\frac{r+l}{r-l} \\ 0 & \frac{2}{t-b} & 0 & -\frac{t+b}{t-b} \\ 0 & 0 & \frac{-2}{f-n} & -\frac{(f+n)}{f-n} \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & \frac{r+l}{2n} & 0 \\ 0 & \frac{2n}{t-b} & 0 & 0 \\ 0 & \frac{2n}{t-b} & 0 & 0 \\ 0 & \frac{2n}{t-b} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & \frac{r+l}{2n} & 0 \\ 0 & 1 & \frac{t+b}{2n} & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Field of View Frustum Scaling

• After the frustum is centered on the -z axis:

- Note that $\frac{n}{t-b} = \cot\left(\frac{\theta}{2}\right)$
- This gives the y mapping $y'' = y' \cot\left(\frac{\theta}{2}\right)$
- Since the window need not be square, we can define the x mapping using the aspect ratio aspect $= \frac{\Delta x}{\Delta y} = \frac{(r-l)}{(t-b)}$
- Then x maps as $x'' = x' \frac{\cot\left(\frac{\theta}{2}\right)}{\text{aspect}}$

DEPARTMENT OF COMPUTER SCIENCES

• This gives us the alternative scaling formulation:

$$\begin{bmatrix} x'\\y'\\z'\\1 \end{bmatrix} = \begin{bmatrix} \frac{\cot\left(\frac{\theta}{2}\right)}{\operatorname{aspect}} & 0 & 0 & 0\\ 0 & \cot\left(\frac{\theta}{2}\right) & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x\\y\\z\\1 \end{bmatrix}$$

• This is used by $gluPerspective(\theta, aspect, n, f)$

Positioning and Orienting the Camera

• Positioned (VRP=view reference point) by

set_view_reference_point(x,y,z)

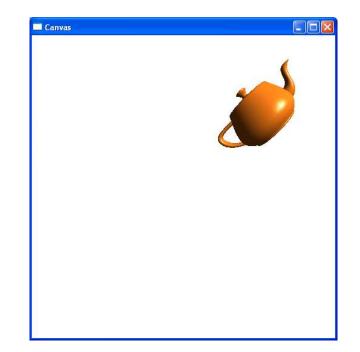

Orientation (VPN=view plane normal and VUP = view-up vector) by

set_view_plane_normal(nx,ny,nz) and set_view_up(vup_x,vup_y,vup_z)

- The projection of the VUP onto the view-plane is a up-direction vector v
- $u=v \ x \ n$ a vector orthogonal to v and n . The (u,v,n) and the VRP yields the viewing coordinate system
- Camera is usually located at a point e called the eye point, and it is pointed at the at point a. This defines VRP, and VPN = e a. Finally use the OpenGL utitility function gluLookAt ()

glMatrixMode(GL_MODELVIEW); glLoadIdentity(); gluLookAt(eyex,eyey,eyez,atx,aty,atz,upx,upy,upz);

glMatrixMode (GL_MODELVIEW); glMatrixMode (GL_PROJECTION); glLoadIdentity(); glFrustum(-1, 1, -1, 1, 2, 7); glFrustum(-3, 1, -3, 1, 2, 7); glMatrixMode (GL_MODELVIEW); glMatrixMode (GL_MODELVIEW); glutSolidTeapot(1);

glMatrixMode (GL_MODELVIEW); gluLookAt(0,0,0, 0,0,-1, 0,1,0); gluLookAt(0,0,0, 0,0,-1, 1,1,0); glMatrixMode (GL_PROJECTION); glLoadIdentity(); glutSolidTeapot(1);

Reading Assignment and News

Before the next class please review Chapter 4 and its practice exercises, of the recommended text.
