Thus for: PRP/PRF in "counter mode" gives us a stream cipher (one-time encryption scheme)

How do we reuse it? Choose a random starting point (called an initialization vector) nonce (value that does not repeat) and "randomized counter mode" a counter: IV = noncell counter

> m₁ m₂ m₃ m₄ divide message into blocks (based on block size of PRF) random value ⊕ IV F(k,IV) F(k,IV+1) F(k,IV+2) F(k,IV+3)

IV C1 C2 C3 C4 ciphertext

Observe: Ciphertext is brager than the message (required for CPA security)

<u>Theorem</u>: Let $F: K \times X \rightarrow Y$ be a secure PRF and let TI_{CTR} denote the randomized counter mode encryption scheme from above for l-block messages ($M = \chi^{\leq \ell}$). Then, for all efficient CPA adversaries A, there exists an efficient PRF adversary B such that

$$(PAAdv[A, Tlerr] \leq \frac{4Q^2k}{|X|} + J \cdot PRFAdv[B,F]$$

 $Q: number of encryption queries$
 $l: number of blocks in message$

Intuition: 1. If there are no collisions (i.e., PRF never evaluated on the same block), then it is as if everything is encrypted under a fresh one-time pad.

2. Collision event: (X, X+1, ..., X+l-1) overlaps with (X', X'+1,..., X'+l-1) when X, X' & X

r probability that x' lies in this interval is $\leq \frac{2\ell}{1\chi_1}$

There are
$$\leq Q^2$$
 possible poirs (x, x') , so by a union bound,
 $Pr[collision] \leq \frac{2LQ^2}{|\chi|}$

3. Remaining factor of 2 in advantage due to intermediate distribution (hybrid argument): Encrypt mo with PRF Encrypt mo with fresh one-time pad Encrypt m, with fresh one-time pad Encrypt m, with PRF PRFAdv[B,F] + $\frac{2lQ^2}{1\chi_1}$

 $\frac{\text{Interpretation}}{\text{If } |X| = 2^{128} \text{ (e.g., AES), and messages are 1 MB long } (2^{16} \text{ blocks)} \text{ and we want the distinguishing advantage}$ $to be below <math>2^{-32}$, then we can use the same key to encrypt $Q \leq \sqrt{\frac{|X| \cdot 2^{-52}}{4L}} = \sqrt{\frac{2^{96}}{2^{19}}} = \sqrt{2^{78}} = 2^{39} (\sim 1 \text{ trillion messages}!)$ Nonce-based counter mode: divide IV into two pieces: IV = nonce || counter

value that does not repeat

Common Choices: 64-bit nonce, 64-bit counter ? only nonce needs to be sent!

(slightly smaller ciphertexts) 96-bit nonce, 32-bit counter

Only requirement for security is that IV closs not repeat:

- Option 1: Choose randomly (either IV or nonce)

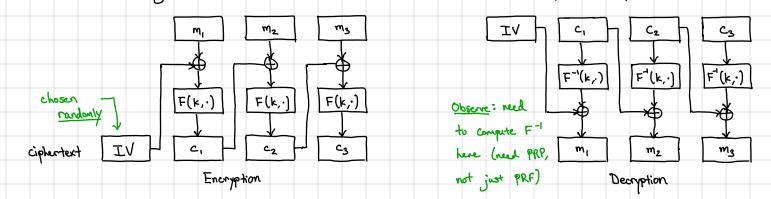

" Option 2: If sender + recipient have shared state (e.g., packed counter), can just use a counter, in which case, IV/ nonce does not have to be sent

(CTR)

Counter mode is parallelizable, simple to - implement, just requires PRF - preferred mode of using block ciphers

Other block cipher modes of operation:

Cipherblock chaining (CBC) : common mode in the past (e.g., TLS 1.0, still widely used today)

Theorem: Let F: K × X -> Y be a secure PRF and let TCBC denote the CBC encryption scheme for L-block messages $(M = X^{\leq k})$. Then, for all efficient CPA adversaries A, there exists an efficient PRF adversary B such that $CPAAdu[A, TI_{CBC}] \leq \frac{2Q^2 l}{|X|} + J \cdot PRFAdv[B,F]$

> CQ: number of encryption queries l: number of blocks in message

Intuition: Similar to analysis of randomized counter mode:

1. Ciphertext is indistinguishable from random string if PRP is evaluated on distinct inputs 2. When encrypting, PRP is involved on L random blocks, so after Q queries, we have QL random blocks. $\Rightarrow Collision probability \leq \frac{Q^2 l^2}{|\chi|} \lesssim this is larger them collision grob. For randomized counter mode by a factor of 2 [overlap of Q random intervals vs. Ql random points]$

3. Factor of 2 arises for some reason as before

Interpretation. CBC mode provides weaker security compared to counter mode: $\frac{2Q^2l^2}{|X|}$ VS. $\frac{4Q^2l}{|X|}$ Concretely: for some parameters as before (1 MB messages, 2^{-32} distinguishing advantage): $Q \leq \sqrt{\frac{11\times1\cdot2^{-32}}{2l^2}} = \sqrt{\frac{2^{128}\cdot2^{-32}}{2(2^{16})^2}} = \sqrt{2^{63}} = 2^{31.5} (~1 \text{ billion messages})$

L> 2⁷⁵ ~ 180 x smaller than using counter mode

Padding in CBC mode: each ciphentext block is computed by feeding a message block into the PRP => message must be an even multiple of the block size => when used in practice, need to pad messages Can we pad with zeroes? Cannot decrypt! What if original message ended with a bunch of zeroes?

<u>Requirement</u>: padding must be invertible

CBC padding in TLS 1.0: if k bytes of padding is needed, then append k bytes to the end, with each byte set to k-1 (for AES-CBC) if O bytes of padding is needed, then append a block of 16 bytes, with each byte equal to 15 L> dummy block needed to ensure pad is invertible [injective functions <u>must</u> expand:] L> called PKCS#5/PKCS#7 (public key cryptography standards)

Need to pad in CBC encryption can be exploited in "padding bracke" attacks

Padding in CBC can be avoided using idea called "ciphentext stealing" (as long as messages are more than 1 block) intersting traffic analysis attack: each keystroke is sent in separate packet, so the packets leaks into on longth

of user's password. Comparing CTR mode to CBC mode: imagine 1 byte messages) CBC mode CTR mode (e.g., encrypted bay strokes) over SSH 1. padding needed 1. no padding needed (shorter ciphertexts) 2. parallelizable 1 block + 1 byte with CTR 2 blocks with CBC 2. sequential 3. only requires PRF (no need to invert) 3. requires PRP < 4. tighter security 4. less tight security requires more structured primitive, more code to implement forward (re-key more often) 5. IVs have to be non-repeating easy to implement: and backward evaluation IV = nonce || counter 5. requires unpredictuble IVs (and spaced for apart) 1 only needs to be non-repeating (can be predictable) _TLS 1.0 used predictable IVs (see HWI for an attack) SSH v1 used a O IV (even worse!) Bottom-line: use randomized or nonce-based counter mode whenever possible: simpler, easier, and better than CBC!

A tempting and bad way to use a block cipher: ECB made (electronic codebook)

[m ₁] m ₂	m ₃) <	Scheme is deterministic! Cannot be CPA secure!
$ F(k_i) F(k_i) $	$F(\underline{k},\cdot)$	lot even semantically secure!
		(mo, mo) V5. (mo, m,) where m, 7 mo
		ciphentext blocks output ciphentext blocks output output are same are different
<u>Encryption</u> : simply apply bloc of the message		
Decryption: Simply invert ear		

NEVER USE ECB MODE FOR ENCRYPTION ?
