

Definition. An encryption scheme  $\Pi_{SE}(\text{Encrypt}, \text{Decrypt})$  is secure against chosen-ciphertext attacks (CCA-secure) if for all efficient adversaries  $A$ ,  $\text{CCAAdv}[A, \Pi_{SE}] = \text{negl.}$  where we define  $\text{CCAAdv}[A, \Pi_{SE}]$  as follows:

adversary can make arbitrary encryption and decryption queries, but cannot decrypt any ciphertexts it received from the challenger (otherwise, adversary can trivially break security)  
 $\rightarrow$  called an "admissibility" criterion

$$\text{CCAAdv}[A, \Pi_{SE}] = |\Pr[b' = 1 \mid b = 0] - \Pr[b' = 1 \mid b = 1]|$$

CCA-security captures above attack scenario where adversary can tamper with ciphertexts

- $\rightarrow$  Rules out possibility of transforming encryption of  $x \parallel z$  to encryption of  $y \parallel z$
- $\rightarrow$  Necessary for security against active adversaries (CPA-security is for security against passive adversaries)
- $\rightarrow$  We will see an example of a real CCA attack in HW1

Theorem. If an encryption scheme  $\Pi_{SE}$  provide authenticated encryption, then it is CCA-secure.

Proof (Idea). Consider an adversary  $A$  in the CCA-security game. Since  $\Pi_{SE}$  provides ciphertext integrity, the challenger's response to the adversary's decryption query will be  $\perp$  with all but negligible probability. This means we can implement the decryption oracle with the "output  $\perp$ " function. But then this is equivalent to the CPA-security game.

[Formalize using a hybrid argument]

simple counter-example: concatenate unused bits to end of ciphertext in a CCA-secure scheme (stripped away during decryption)

Note: Converse of the above is not true since CCA-security  $\nRightarrow$  ciphertext integrity.

$\rightarrow$  However, CCA-security + plaintext integrity  $\Rightarrow$  authenticated encryption

Take-away: Authenticated encryption captures meaningful confidentiality + integrity properties; provides active security

Encrypt-then-MAC: Let  $(\text{Encrypt}, \text{Verify})$  be a CPA-secure encryption scheme and  $(\text{Sign}, \text{Verify})$  be a secure MAC. We define Encrypt-then-MAC to be the following scheme:

$\text{Encrypt}'((k_E, k_M), m): c \leftarrow \text{Encrypt}(k_E, m)$

$\uparrow \quad \uparrow$   
independent keys

$t \leftarrow \text{Sign}(k_M, c)$

output  $(c, t)$

$\text{Decrypt}'((k_E, k_M), (c, t)): \text{if } \text{Verify}(k_M, c, t) = 0, \text{ output } \perp$   
 else, output  $\text{Decrypt}(k_E, c)$

Theorem. If  $(\text{Encrypt}, \text{Decrypt})$  is CPA-secure and  $(\text{Sign}, \text{Verify})$  is a secure MAC, then  $(\text{Encrypt}', \text{Verify}')$  is an authenticated encryption scheme.

Proof (Sketch). CPA-security follows by CPA-security of  $(\text{Encrypt}, \text{Decrypt})$ . Specifically, the MAC is computed on ciphertexts and not the messages. MAC key is independent of encryption key so cannot compromise CPA-security. Ciphertext integrity follows directly from MAC security (i.e., any valid ciphertext must contain a new tag on some ciphertext that was not given to the adversary by the challenger).

Important notes:- Encryption + MAC keys must be independent. Above proof required this (in the formal reduction, need to be able to simulate ciphertexts/MACs — only possible if reduction can choose its own key).

↳ Can also give explicit constructions that are completely broken if same key is used (i.e., both properties fail to hold)

↳ In general, never reuse cryptographic keys in different schemes; instead, sample fresh, independent keys!

- MAC needs to be computed over the entire ciphertext

- Early version of ISO 19772 for AE did not MAC IV (CBC used for CPA-secure encryption)

- RNCryptor in Apple iOS (for data encryption) also problematic (HMAC not applied to encryption IV)

} means first block (i.e., "header") is malleable

MAC-then-Encrypt: Let  $(\text{Encrypt}, \text{Verify})$  be a CPA-secure encryption scheme and  $(\text{Sign}, \text{Verify})$  be a secure MAC. We define MAC-then-Encrypt to be the following scheme:

$\text{Encrypt}'((k_E, k_M), m): t \leftarrow \text{Sign}(k_M, m)$

$c \leftarrow \text{Encrypt}(k_E, (m, t))$

output  $c$

$\text{Decrypt}'((k_E, k_M), (c, t)): \text{compute } (m, t) \leftarrow \text{Decrypt}(k_E, c)$

if  $\text{Verify}(k_M, m, t) = 1$ , output  $m$ , else, output  $\perp$

Not generally secure! SSL 3.0 (precursor to TLS) used randomized CBC + secure MAC

↳ Simple CCA attack on scheme (by exploiting padding in CBC encryption)

[POODLE attack on SSL 3.0 can decrypt all encrypted traffic using a CCA attack]

Padding is a common source of problems with MAC-then-Encrypt systems [see HW2 for an example]

In the past, libraries provided separate encryption + MAC interfaces — common source of errors

↳ Good library design for crypto should minimize ways for users to make errors, not provide more flexibility

Today, there are standard block cipher modes of operation that provide authenticated encryption

- One of the most widely used is GCM (Galois counter mode) — standardized by NIST in 2007

GCM mode: follows encrypt-then-MAC paradigm

- CPA-secure encryption is nonce-based counter mode

- MAC is a Carter-Wegman MAC

↳ "encrypted one-time MAC"

} Most commonly used in conjunction with AES  
(AES-GCM provides authenticated encryption)

GCM encryption: encrypt message with AES in counter mode

compute Carter-Wegman MAC on resulting message using GHASH as the underlying hash function and the block cipher as underlying PRF

↖ Galois Hash

↖ key derived from PRF evaluation at  $0^n$

↑ GHASH operates on blocks of 128-bits

operations can be expressed as operations over

$GF(2^{128})$  — Galois field with  $2^{128}$  elements

implemented in hardware — very fast!

Typically, use AES-GCM for authenticated encryption

Oftentimes, only part of the payload needs to be hidden, but still needs to be authenticated

↳ e.g., sending packets over a network: desire confidentiality for packet body, but only integrity for packet headers (otherwise, cannot route!)

AEAD: authenticated encryption with associated data

↳ augment encryption scheme with additional plaintext input; resulting ciphertext ensures integrity for associated data, but not confidentiality (will not define formally here but follows straightforwardly from AE definitions)

↳ can construct directly via "encrypt-then-MAC": namely, encrypt payload and MAC the ciphertext + associated data

↳ AES-GCM is an AEAD scheme
