

# POS Tagging

## HMM POS Tagging

- ▶ Penn Treebank English POS tagging (see homework): 44 tags
- ▶ Baseline: assign each word its most frequent tag: ~90% accuracy
- ▶ Trigram HMM (model pairs of tags): ~95% accuracy / 55% on words not seen in train
- ▶ TnT tagger (Brants 1998, tuned HMM): 96.2% acc / 86.0% on unks
- ▶ CRF tagger (Toutanova + Manning 2000): 96.9% / 87.0%
- ▶ State-of-the-art (BiLSTM-CRFs, BERT): 97.5% / 89%+

## Remaining Errors

- ▶ Lexicon gap (word not seen with that tag in training): 4.5% of errors
- ▶ Unknown word: 4.5%
- ▶ Could get right: 16% (many of these involve parsing!)
- ▶ Difficult linguistics: 20%

VBD / VBP? (past or present?)

*They set up absurd situations, detached from reality*

- ▶ Underspecified / unclear, gold standard inconsistent / wrong: **58%**

adjective or verbal participle? JJ / VBN?

*a \$ 10 million fourth-quarter charge against discontinued operations*

Manning 2011 "Part-of-Speech Tagging from 97% to 100%: Is It Time for Some Linguistics?"

## CRFs and NER

## Named Entity Recognition

B-PER I-PER O O O B-LOC O O O B-ORG O O  
 Barack Obama will travel to Hangzhou today for the G20 meeting .  
 PERSON LOC ORG

- ▶ Frame as a sequence problem with a BIOES-style tagset: begin, inside, outside
- ▶ Why might an HMM not do so well here?
  - ▶ Lots of O's, so tags aren't as informative about context
  - ▶ Want to use context features (to Hangzhou => Hangzhou is a LOC)
- ▶ Conditional random fields (CRFs) can help solve these problems

## HMMs

- ▶ Big advantage: transitions, scoring pairs of adjacent y's

- ▶ Big downside: not able to incorporate useful word context information
- ▶ Solution: switch from generative to discriminative model (conditional random fields) so we can condition on the *entire input*.
- ▶ Conditional random fields: logistic regression + features on pairs of y's

## Tagging with Logistic Regression

- ▶ Logistic regression over each tag individually: "different features" approach to features for a single tag

$$P(y_i = y | \mathbf{x}, i) = \frac{\exp(\mathbf{w}^\top \mathbf{f}(y, i, \mathbf{x}))}{\sum_{y' \in \mathcal{Y}} \exp(\mathbf{w}^\top \mathbf{f}(y', i, \mathbf{x}))}$$

- ▶ Over all tags:

$$P(\mathbf{y} = \tilde{\mathbf{y}} | \mathbf{x}) = \prod_{i=1}^n P(y_i = \tilde{y}_i | \mathbf{x}, i) = \frac{1}{Z} \exp\left(\sum_{i=1}^n \mathbf{w}^\top \mathbf{f}(\tilde{y}_i, i, \mathbf{x})\right)$$

- ▶ Score of a prediction: sum of weights dot features over each individual predicted tag (this is a simple CRF but not the general form)
- ▶ Set Z equal to the product of denominators; we'll discuss this in a few slides

## Example

B-PER I-PER O O

Barack Obama will travel

feats =  $f_e(\text{B-PER}, i=1, \mathbf{x}) + f_e(\text{I-PER}, i=2, \mathbf{x}) + f_e(\text{O}, i=3, \mathbf{x}) + f_e(\text{O}, i=4, \mathbf{x})$

[CurrWord=Obama & label=I-PER, PrevWord=Barack & label=I-PER, CurrWordIsCapitalized & label=I-PER, ...]

B-PER B-PER O O

Barack Obama will travel

feats =  $f_e(\text{B-PER}, i=1, \mathbf{x}) + f_e(\text{B-PER}, i=2, \mathbf{x}) + f_e(\text{O}, i=3, \mathbf{x}) + f_e(\text{O}, i=4, \mathbf{x})$

## Adding Structure

$$P(\mathbf{y} = \tilde{\mathbf{y}}|\mathbf{x}) = \frac{1}{Z} \exp \left( \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}(\tilde{y}_i, i, \mathbf{x}) \right)$$

- ▶ We want to be able to learn that some tags don't follow other tags — want to have features on tag pairs

$$P(\mathbf{y} = \tilde{\mathbf{y}}|\mathbf{x}) = \frac{1}{Z} \exp \left( \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_e(\tilde{y}_i, i, \mathbf{x}) + \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_t(\tilde{y}_i, \tilde{y}_{i+1}, i, \mathbf{x}) \right)$$

- ▶ Score: sum of weights dot  $f_e$  features over each predicted tag (“emissions”) plus sum of weights dot  $f_t$  features over tag pairs (“transitions”)
- ▶ This is a sequential CRF

## Example

B-PER I-PER O O

Barack Obama will travel

feats =  $f_e(\text{B-PER}, i=1, \mathbf{x}) + f_e(\text{I-PER}, i=2, \mathbf{x}) + f_e(\text{O}, i=3, \mathbf{x}) + f_e(\text{O}, i=4, \mathbf{x})$   
+  $f_t(\text{B-PER}, \text{I-PER}, i=1, \mathbf{x}) + f_t(\text{I-PER}, \text{O}, i=2, \mathbf{x}) + f_t(\text{O}, \text{O}, i=3, \mathbf{x})$

B-PER B-PER O O

Barack Obama will travel

feats =  $f_e(\text{B-PER}, i=1, \mathbf{x}) + f_e(\text{B-PER}, i=2, \mathbf{x}) + f_e(\text{O}, i=3, \mathbf{x}) + f_e(\text{O}, i=4, \mathbf{x})$   
+  $f_t(\text{B-PER}, \text{B-PER}, i=1, \mathbf{x}) + f_t(\text{B-PER}, \text{O}, i=2, \mathbf{x}) + f_t(\text{O}, \text{O}, i=3, \mathbf{x})$

- ▶ Obama can start a new named entity (emission feats look okay), but we're not likely to have two PER entities in a row (transition feats)

## Features for NER

$$P(\mathbf{y} = \tilde{\mathbf{y}}|\mathbf{x}) = \frac{1}{Z} \exp \left( \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_e(\tilde{y}_i, i, \mathbf{x}) + \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_t(\tilde{y}_i, \tilde{y}_{i+1}, i, \mathbf{x}) \right)$$

O B-LOC

Barack Obama will travel to Hangzhou today for the G20 meeting .

Transitions:  $f_t(\text{O}, \text{B-LOC}, i = 5, \mathbf{x}) = \text{Indicator}[\text{O} \rightarrow \text{B-LOC}]$

Emissions:  $f_e(\text{B-LOC}, i = 6, \mathbf{x}) = \text{Indicator}[\text{B-LOC} \ \& \ \text{Curr word} = \text{Hangzhou}]$   
 $\text{Indicator}[\text{B-LOC} \ \& \ \text{Prev word} = \text{to}]$

- ▶ We couldn't use a “previous word” feature in the HMM at all!

## Conditional Random Fields

$$P(\mathbf{y} = \tilde{\mathbf{y}}|\mathbf{x}) = \frac{1}{Z} \exp \left( \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_e(\tilde{y}_i, i, \mathbf{x}) + \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_t(\tilde{y}_i, \tilde{y}_{i+1}, i, \mathbf{x}) \right)$$

normalizer Z: must make this a probability distribution over all possible seqs

$$Z = \sum_{\mathbf{y}' \in \mathcal{Y}^n} \exp \left( \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_e(y'_i, i, \mathbf{x}) + \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_t(y'_i, y'_{i+1}, i, \mathbf{x}) \right)$$

## Inference and Learning

$$P(\mathbf{y} = \tilde{\mathbf{y}}|\mathbf{x}) = \frac{1}{Z} \exp \left( \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_e(\tilde{y}_i, i, \mathbf{x}) + \sum_{i=1}^n \mathbf{w}^\top \mathbf{f}_t(\tilde{y}_i, \tilde{y}_{i+1}, i, \mathbf{x}) \right)$$

- ▶ Inference: Can use the Viterbi algorithm to find the highest scoring path. Replace HMM log probs with “scores” from weights dot features

$$\log P(x_i|y_i) \rightarrow \mathbf{w}^\top \mathbf{f}_e(y_i, i, \mathbf{x}) \quad (\text{initial distribution is removed})$$

$$\log P(y_i|y_{i-1}) \rightarrow \mathbf{w}^\top \mathbf{f}_t(y_{i-1}, y_i, i, \mathbf{x})$$

- ▶ Learning: requires running *forward-backward* (like Viterbi but with summing instead of maxing over  $y$ 's) to compute Z, then doing some tricky math to compute gradients [outside scope of the course/not on midterm]

## Takeaways

- ▶ CRFs provide a way to build structured feature-based models: logistic regression over structured objects like sequences
- ▶ Inference and learning can still be done efficiently but require dynamic programming
- ▶ CRFs don't have to be linear models; can use scores derived from neural networks (“neural CRFs”)
