# CS388: Natural Language Processing

Lecture 5: Word Embeddings

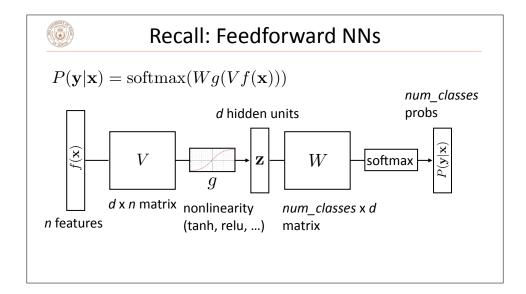

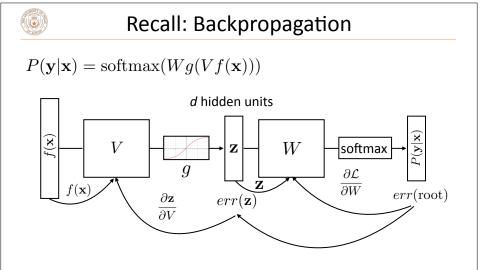

### Administrivia

- Project 1 due Thursday
- Project 2 released Thursday

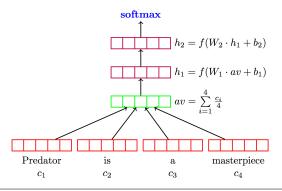

# **Recall: Deep Averaging Networks**

 Deep Averaging Networks: feedforward neural network on average of word embeddings from input

lyyer et al. (2015)

#### This Lecture

- Word representations
- word2vec/GloVe
- Evaluating word embeddings

**Word Representations** 

## **Word Representations**

- Neural networks work very well at continuous data, but words are discrete
- Continuous model <-> expects continuous semantics from input
- "You shall know a word by the company it keeps" Firth (1957)

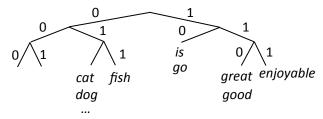

[Finch and Chater 92, Shuetze 93, many others]

slide credit: Dan Klein

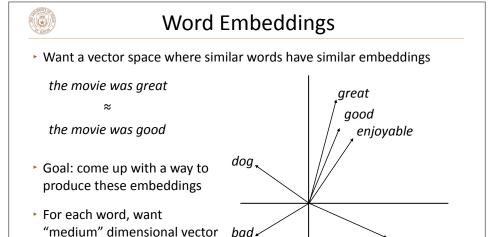

## **Discrete Word Representations**

 Brown clusters: hierarchical agglomerative hard clustering (each word has one cluster, not some posterior distribution like in mixture models)

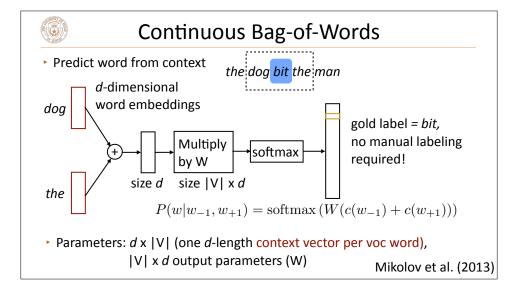

- Maximize  $P(w_i|w_{i-1}) = P(c_i|c_{i-1})P(w_i|c_i)$
- Useful features for tasks like NER, not suitable for NNs
   Brown et al. (1992)

(50-300 dims) representing it

is

### word2vec

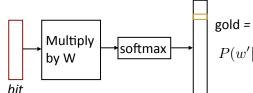

## Skip-Gram

Predict one word of context from word

$$P(w'|w) = \operatorname{softmax}(We(w))$$

- Another training example: bit -> the
- Parameters: d x |V| vectors, |V| x d output parameters (W) (also usable as vectors!)

Mikolov et al. (2013)

## **Using Skip-Gram**

Context window size: how many words around the "center" word do we look?

the dog bit the man

k=1: two words of context

k=2: four words of context

- Advantages/disadvantages of different sizes of k?
- Training: maximize log likelihood of the examples derived given k, summed over a corpus (but we'll never use the model as is, only its embeddings)
- Initialization: need to randomly initialize in a reasonable way
- Vector size: controls capacity of model

Mikolov et al. (2013)

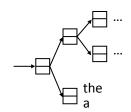

### Hierarchical Softmax

 $P(w|w_{-1}, w_{+1}) = \operatorname{softmax}(W(c(w_{-1}) + c(w_{+1}))) \qquad P(w'|w) = \operatorname{softmax}(We(w))$ 

► Matmul + softmax over |V| is very slow to compute for CBOW and SG

- Huffman encode vocabulary, use binary classifiers to decide which branch to take
- ▶ log(|V|) binary decisions

Mikolov et al. (2013)

- Standard softmax: |V| dot products of size d
- Hierarchical softmax: log(|V|) dot products of size d, |V| x d parameters

# Skip-Gram with Negative Sampling

 Take (word, context) pairs and classify them as "real" or not. Create random negative examples by sampling from unigram distribution

$$\begin{array}{ll} \textit{(bit, the)} => +1 \\ \textit{(bit, cat)} => -1 \\ \textit{(bit, a)} => -1 \\ \textit{(bit, fish)} => -1 \end{array} \qquad \begin{array}{ll} P(y=1|w,c) = \frac{e^{w\cdot c}}{e^{w\cdot c}+1} & \text{words in similar contexts select for similar $c$ vectors} \end{array}$$

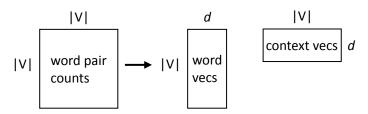

- ► d x |V| vectors, d x |V| context vectors (same # of params as before)
- Objective =  $\log P(y=1|w,c) + \frac{1}{k} \sum_{i=1}^n \log P(y=0|w_i,c)$  sampled

Mikolov et al. (2013)

### Connections with Matrix Factorization

 Skip-gram model looks at word-word co-occurrences and produces two types of vectors

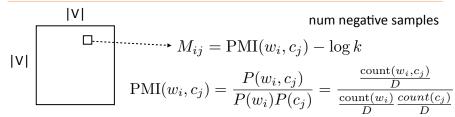

Looks almost like a matrix factorization...

Levy et al. (2014)

## Skip-Gram as Matrix Factorization

Skip-gram objective *exactly* corresponds to factoring this matrix:

- ► If we sample negative examples from the unigram distribution over words
- ...and it's a weighted factorization problem (weighted by word freq)

Levy et al. (2014)

## GloVe (Global Vectors)

|V|

 Also operates on counts matrix, weighted regression on the log co-occurrence matrix |V| word pair counts

- $\qquad \qquad \textbf{Objective} = \sum_{i,j} f(\operatorname{count}(w_i,c_j)) \left(w_i^\top c_j + a_i + b_j \log \operatorname{count}(w_i,c_j))\right)^2$
- Constant in the dataset size (just need counts), quadratic in voc size
- ▶ By far the most common word vectors used today (30000+ citations)

Pennington et al. (2014)

## GloVe (**Glo**bal **Ve**ctors): Example

Objective = 
$$\sum_{i,j} f(\operatorname{count}(w_i, c_j)) \left(w_i^{\top} c_j + a_i + b_j - \operatorname{log} \operatorname{count}(w_i, c_j))\right)^2$$

the dog cat ran

Linear regression with 16 points:
each element is plugged into the above equation

cat 200 0 0 15

ran 0 15 15 0

Linear regression with 16 points: each element is plugged into the above equation

+ constant = log count of pair

(made up values — matrix will generally be symmetric, though)

Pennington et al. (2014)

# **Analogies**

king

queen

man

woman

(king - man) + woman = queen

king + (woman - man) = queen

- Why would this be?
- woman man captures the difference in the contexts that these occur in
- Dominant change: more "he" with man and "she" with woman — similar to difference between king and queen
- Can evaluate on this as well

#### GloVe Motivation

Table 1: Co-occurrence probabilities for target words ice and steam with selected context words from a 6 billion token corpus. Only in the ratio does noise from non-discriminative words like water and fashion cancel out, so that large values (much greater than 1) correlate well with properties specific to ice, and small values (much less than 1) correlate well with properties specific of steam.

Probability and Ratio	k = solid	k = gas	k = water	k = fashion
		$6.6 \times 10^{-5}$		
P(k steam)	$2.2\times10^{-5}$	$7.8\times10^{-4}$	$2.2\times10^{-3}$	$1.8\times10^{-5}$
P(k ice)/P(k steam)	8.9	$8.5 \times 10^{-2}$	1.36	0.96

► GloVe objective is derived to preserve regularities in cooccurrence of words with other words  $F\left((w_i - w_j)^T \tilde{w}_k\right) = \frac{P_{ik}}{P_{ik}}$ 

Pennington et al. (2014)

#### Other Methods

## fastText: Sub-word Embeddings

Same as SGNS, but break words down into n-grams with n = 3 to 6

where:

3-grams: <wh, whe, her, ere, re> 4-grams: <whe, wher, here, ere>, 5-grams: <wher, where, here>, 6-grams: <where, where>

Replace  $w \cdot c$  in skip-gram computation with  $\left(\sum_{g \in \operatorname{ngrams}} w_g \cdot c\right)$ 

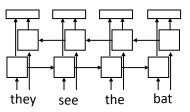

Advantages?

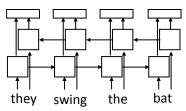

Bojanowski et al. (2017)

# Preview: Context-dependent Embeddings

► How to handle different word senses? One vector for bat

- Train a neural language model to predict the next word given previous words in the sentence, use its internal representations as word vectors
- · Context-sensitive word embeddings: depend on rest of the sentence
- ► Huge improvements across nearly all NLP tasks over GloVe

Peters et al. (2018)

## **Compositional Semantics**

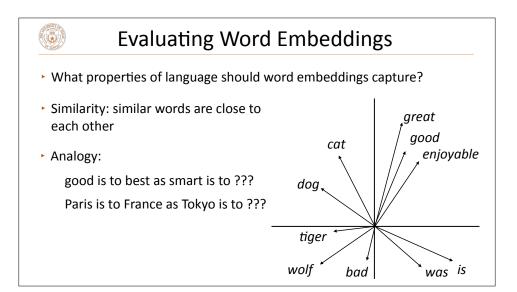

- ► What if we want embedding representations for whole sentences?
- Skip-thought vectors (Kiros et al., 2015), similar to skip-gram generalized to a sentence level (more later)
- Is there a way we can compose vectors to make sentence representations? Summing?
- ► Will return to this in a few weeks as we move on to syntax and semantics

## **Using Word Embeddings**

- ► Approach 1: learn embeddings as parameters from your data
  - Often works pretty well
- Approach 2: initialize using GloVe, keep fixed
  - Faster because no need to update these parameters
- Approach 3: initialize using GloVe, fine-tune
  - Works best for some tasks

# **Evaluating Word Embeddings**

## Similarity

Method	WordSim	WordSim	Bruni et al.	Radinsky et al.	Luong et al.	Hill et al.
	Similarity	Relatedness	MEN	M. Turk	Rare Words	SimLex
PPMI	.755	.697	.745	.686	.462	.393
SVD	.793	.691	.778	.666	.514	.432
SGNS	.793	.685	.774	.693	.470	.438
GloVe	.725	.604	.729	.632	.403	.398

- ► SVD = singular value decomposition on PMI matrix
- GloVe does not appear to be the best when experiments are carefully controlled, but it depends on hyperparameters + these distinctions don't matter in practice

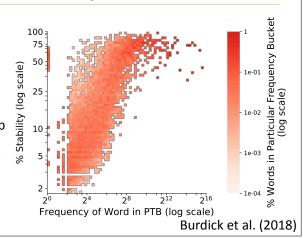

Levy et al. (2015)

#### To what extent are the relationships captured by word embeddings consistent?

 Stability: percent overlap between nearest neighbors in embedding space if you retrain embeddings from different initialization

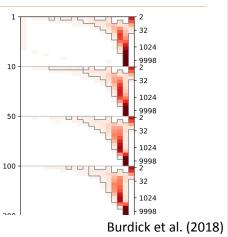

# Stability

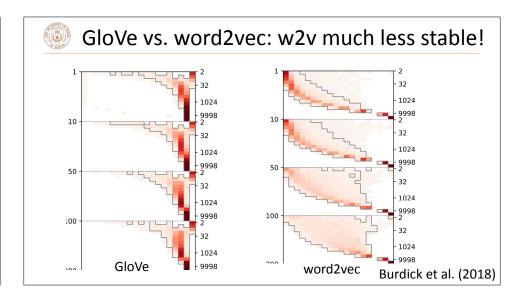

## Stability: GloVe

- ► Left y-axis: bucketed corpus frequency
- ► Right y-axis: number of neighbors
- x-axis: percent of neighbors stable across samples
- Being all the way to the right is better (most neighbors are stable)

## What can go wrong with word embeddings?

What's wrong with learning a word's "meaning" from its usage?

Ukraine's deputy defense minister resigns amid corruption allegations

From 2015 through 2020, there were at least 2,070 unintentional shootings by children under 18 in the US, according to a report from Everytown. Those shootings resulted in 765 deaths and 1,366 injuries.

Convicted child sex trafficker Ghislaine Maxwell has said a decades-old photograph of Prince Andrew with his sexual abuse accuser Virginia Giuffre is "fake," in a series of interviews from prison.

## What do we mean by bias?

▶ Identify she - he axis in word vector space, project words onto this axis

Nearest neighbor of (b - a + c)

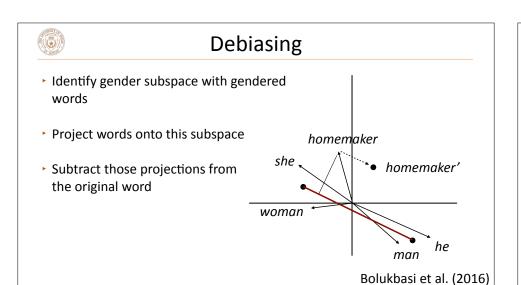

1. homemaker 3. receptionist 4. librarian 5. socialite 6. hairdresser 8. bookkeeper 9. stylist 10. housekeeper 11. interior designer 12. guidance counselor

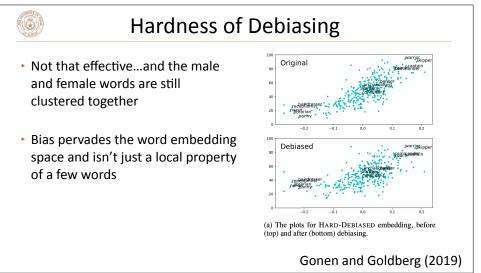

2. skipper 4. philosopher 5. captain 6. architect 7. financier 8. warrior 9. broadcaster 11. figher pilot

#### Bolukbasi et al. (2016)

black → homeless caucasian → hillbilly asian  $\rightarrow$  laborer black → landowner  $muslim \rightarrow powerless$ christian → familial muslim → warzone

Manzini et al. (2019)

## **Takeaways**

- Word vectors: learning word -> context mappings has given way to matrix factorization approaches (constant in dataset size)
- Lots of pretrained embeddings work well in practice, they capture some desirable properties
- ► Even better: context-sensitive word embeddings (ELMo)
- ► Next time: language modeling and Transformers
