Lecture 7: Validity Proofs and Properties of FOL

Işıl Dillig

Overview

- ▶ Agenda for today:
 - ▶ Semantic argument method for proving FOL validity
 - ▶ Important properties of FOL

Motivation for semantic argument method

- ▶ So far, defined what it means for FOL formula to be valid, but how to prove validity?
- ▶ Will extend **semantic argument method** from PL to FOL
- ▶ **Recall:** In propositional logic, satisfiability and validity are dual concepts:

F is valid iff $\neg F$ is unsatisfiable
- ▶ Since this duality also holds in FOL, we'll focus on validity

Semantic Argument Method to Prove Validity

- ▶ **Recall:** Semantic argument method is a proof by contradiction.
- ▶ **Basic idea:** Assume that F is not valid, i.e., there exists some S, σ such that $S, \sigma \not\models F$
- ▶ Then, apply proof rules.
- ▶ If can derive contradiction on **every** branch of proof, F is valid.

New Proof Rules

- ▶ All proof rules from prop. logic carry over but need new rules for quantifiers.
- ▶ **Universal elimination I:**
$$\frac{U, I, \sigma \models \forall x.F \text{ (for any } o \in U)}{U, I, \sigma[x \mapsto o] \models F}$$
- ▶ **Example:** Suppose $U, I, \sigma \models \forall x.hates(jack, x)$
- ▶ Using the above proof rule, we can conclude:

$$U, I, \sigma[x \mapsto I(jack)] \models hates(jack, x)$$

Universal Elimination Rule II

- ▶ **Universal elimination II:**
$$\frac{U, I, \sigma \not\models \forall x.F \text{ (for a fresh } o \in U)}{U, I, \sigma[x \mapsto o] \not\models F}$$
- ▶ By a fresh object constant, we mean an object that has not been previously used in the proof
- ▶ Why do we have this restriction?

Existential Elimination Rule I

- ▶ Existential elimination I:

$$\frac{U, I, \sigma \models \exists x.F \quad (\text{for a fresh } o \in U)}{U, I, \sigma[x \mapsto o] \models F}$$

- ▶ Again, **fresh** means an object that has not been used before

Existential Elimination Rule II

- ▶ Existential elimination II:

$$\frac{U, I, \sigma \not\models \exists x.F \quad (\text{for any } o \in U)}{U, I, \sigma[x \mapsto o] \not\models F}$$

- ▶ If U, I, σ do not entail $\exists x.F$, this means there does not exist any object for which F holds
- ▶ Thus, no matter what object x maps to, it still won't entail F

Final Proof Rule

- ▶ Finally, we need a rule for deriving for contradictions

- ▶ Contradiction rule:

$$\frac{U, I, \sigma \models p(s_1, \dots, s_n) \quad U, I, \sigma \not\models p(t_1, \dots, t_n) \quad (I, \sigma)(s_i) = (I, \sigma)(t_i) \text{ for all } i \in [1, n]}{U, I, \sigma \models \perp}$$

- ▶ **Example:** Suppose we have $S, \{x \mapsto a\} \models p(x)$ and $S, \{y \mapsto a\} \not\models p(y)$
- ▶ The proof rule for contradiction allows us to derive \perp

Example 1: Proving Validity

- ▶ Prove the validity of formula:

$$F : (\forall x.p(x)) \rightarrow (\forall y.p(y))$$

- ▶ We start by assuming it is not valid, i.e., there exists some S, σ such that $S, \sigma \not\models F$.

Example 2

- ▶ Is this formula valid?

$$F : (\forall x. (p(x) \vee q(x))) \rightarrow (\exists x.p(x) \vee \forall x.q(x))$$

- ▶ Informal argument: Suppose $\forall x.(p(x) \vee q(x))$ holds
- ▶ This means either $q(x)$ for all objects (i.e., $\forall x.q(x)$)
- ▶ Or if $q(x)$ does not hold for some object o , then $p(x)$ must hold for that object o (i.e., $\exists x.p(x)$)

Example 2, cont

- ▶ Let's now prove validity using semantic argument method

$$F : (\forall x. (p(x) \vee q(x))) \rightarrow (\exists x.p(x) \vee \forall x.q(x))$$

- ▶ Let's assume there is some S, σ that does not entail ϕ , and derive contradiction on all branches

Example 3

- ▶ Is this formula valid?

$$F : (\forall x.p(x, x)) \rightarrow (\exists x.\forall y.p(x, y))$$

- ▶ How do you prove it's not valid?
- ▶ Falsifying interpretation:

Example 4

- ▶ Is the following formula valid?

$$(\forall x.(p(x) \wedge q(x))) \rightarrow (\forall x.p(x)) \wedge (\forall x.q(x))$$

- ▶
- ▶
- ▶

Example 4, cont

- ▶ Let's prove validity using semantic argument method:

$$F : (\forall x.(p(x) \wedge q(x))) \rightarrow (\forall x.p(x)) \wedge (\forall x.q(x))$$

- ▶ Assume there is a S, σ such that $S, \sigma \not\models F$

Soundness and Completeness of Proof Rules

- ▶ The proof rules we used are sound and complete.
- ▶ **Soundness:** If every branch of semantic argument proof derives a contradiction, then F is indeed valid.
- ▶ **Translation:** The proof system does not reach wrong conclusions
- ▶ **Completeness:** If formula F is valid, then there exists a finite-length proof in which every branch derives \perp .
- ▶ **Translation:** There are no valid first-order formulas which we cannot prove to be valid using our proof rules.

Important Properties of First Order Logic

- ▶ **Really important result:** It is undecidable whether a first-order formula is valid. (Church and Turing)
- ▶ **Review:** A problem is decidable iff there exists a procedure P such that, for any input:
 1. P halts and says "yes" if the answer is positive
 2. halts and says "no" if the answer is negative
- ▶ But, what about the completeness result? Doesn't this contradict undecidability?

Semidecidability of First-Order Logic

- ▶ First-order logic is **semidecidable**
- ▶ A decision problem is semidecidable iff there exists a procedure P such that, for any input:
 1. P halts and says "yes" if the answer is positive
 2. P may not terminate if the answer is negative
- ▶ Thus, there exists an algorithm that always terminates and says if any arbitrary FOL formula is valid
- ▶ But no algorithm is guaranteed to terminate if the FOL formula is not valid

Decidable Fragments of First-Order Logic

- ▶ Although full first order logic is not decidable, there are fragments of FOL that are decidable.
- ▶ A **fragment** of FOL is a syntactically restricted subset of full FOL: e.g., no functions, or only universal quantifiers, etc.
- ▶ Some decidable fragments:
 - ▶ Quantifier-free first order logic
 - ▶ Monadic first-order logic
 - ▶ Bernays-Schönfinkel class

19/31

Quantifier-Free Fragment of FOL

- ▶ The quantifier-free fragment of FOL is the syntactically restricted subset of FOL where formulas do not contain universal or existential quantifiers.
- ▶ Determining validity and satisfiability in quantifier-free FOL is decidable (NP-complete).

CS389L: Automated Logical Reasoning Lecture 7: Validity Proofs and Properties of FOL

20/31

Monadic First-Order Logic

- ▶ **Pure monadic FOL**: all predicates are **monadic** (i.e., arity 1) and no function constants.
- ▶ **Impure monadic FOL**: both monadic predicates and monadic function constants allowed
- ▶ **Result**: Monadic first-order logic is decidable (both versions)
- ▶ However, if we add even a single binary predicate, the logic becomes undecidable.

21/31

Bernays-Schönfinkel Class

- ▶ The Bernays-Schönfinkel class is a fragment of FOL where:
 1. there are no function constants,
 2. only formulas of the form:
$$\exists x_1, \dots, \exists x_n. \forall y_1, \dots, \forall y_m. F(x_1, \dots, x_n, y_1, \dots, y_m)$$
- ▶ **Result**: The Bernays-Schönfinkel fragment of FOL is decidable
- ▶ Also known as **Effectively Propositional Logic**

22/31

Compactness of First-Order Logic

- ▶ Another important property of FOL is compactness.
- ▶ A logic is called **compact** if an infinite set of sentences Γ is satisfiable iff every finite subset of Γ is satisfiable.
- ▶ **Theorem (due to Gödel)**: **First-order logic is compact.**

23/31

Consequences of Compactness

- ▶ Proof of compactness might look like a useless property, but it has very interesting consequences!
- ▶ Compactness can be used to show that a variety of interesting properties are not expressible in first-order logic.
- ▶ For instance, we can use compactness theorem to show that **transitive closure** is not expressible in first order logic.

CS389L: Automated Logical Reasoning Lecture 7: Validity Proofs and Properties of FOL

24/31

Transitive Closure

- ▶ Given a directed graph $G = (V, E)$, the **transitive closure** of G is defined as the graph $G^* = (V, E^*)$ where:

$$E^* = \{(n, n') \mid \text{if there is a path from vertex } n \text{ to } n'\}$$

- ▶ **Observe:** A binary predicate $p(t, t')$ be viewed as a graph containing an edge from node t to t'
- ▶ Thus, the concept of transitive closure applies to binary predicates as well
- ▶ A binary predicate T is the transitive closure of predicate p iff $\langle t_0, t_n \rangle \in T$ iff there exists some sequence t_0, t_1, \dots, t_n such that $\langle t_i, t_{i+1} \rangle \in p$

“Expressing” Transitive Closure in FOL

- ▶ At first glance, it looks like transitive closure T of binary relation p is expressible in FOL:

$$\forall x, \forall z. (T(x, z) \leftrightarrow (p(x, z) \vee \exists y. p(x, y) \wedge T(y, z)))$$

- ▶ But this formula does not describe transitive closure at all!
- ▶ To see why, consider $U = \mathbb{N}$, p is equality predicate, and T is relation that is true for *any* number x, y .
- ▶ Clearly, this T is not the transitive closure of equality, but this structure is actually a model of the formula.
- ▶ Thus, the formula above is not a definition of transitive closure at all!

Transitive Closure and FOL

- ▶ In fact, no matter how hard we try to correct this definition, we cannot express transitive closure in FOL
- ▶ Will use compactness theorem to show that transitive closure is not expressible in FOL
- ▶ **Compactness:** An infinite set of sentences Γ is satisfiable iff every finite subset of Γ is satisfiable.
- ▶ For contradiction, suppose transitive closure is expressible in first order logic
- ▶ Let Γ be a (possibly infinite) set of sentences expressing that T is the transitive closure of p .

Proof I

- ▶ $\Psi^n(a, b)$ encode the proposition: there is no path of length n from a to b .
- ▶ In particular, $\Psi^1 = \neg p(a, b)$
- ▶ Similarly,

$$\Psi^n = \neg \exists x_1, \dots, x_{n-1}. (p(a, x_1) \wedge p(x_1, x_2) \wedge \dots \wedge p(x_{n-1}, b))$$

Proof II

- ▶ **Recall:** Γ is a set of propositions encoding T is transitive closure of p .
- ▶ Now, construct Γ' as follows:

$$\Gamma' = \Gamma \cup \{T(a, b), \Psi^1, \Psi^2, \Psi^3, \dots, \}$$
- ▶ **Observe:** Γ' is unsatisfiable because:
 1. Since Γ encodes that T is transitive closure of p , $T(a, b)$ says there is some path from a to b
 2. The infinite set of propositions Ψ^1, Ψ^2, \dots say that there is no path of any length from a to b

Proof III

- ▶ Now, consider any finite subset of Γ' :

$$\Gamma' = \Gamma \cup \{T(a, b), \Psi^1, \Psi^2, \Psi^3, \dots, \}$$
- ▶ Clearly, any finite subset does not contain Ψ_i for some i .
- ▶ **Observe:** This finite subset is satisfied by a model where there is a path of length i from a to b
- ▶ Thus, every finite subset of Γ' is satisfiable.
- ▶ By the compactness theorem, this would imply Γ' is also satisfiable
- ▶ But we just showed that Γ' is unsatisfiable!
- ▶ Thus, transitive closure cannot be expressed in FOL!

Summary

- ▶ Semantic argument method for proving validity in FOL
- ▶ Important properties: semi-decidability, compactness
- ▶ Next lecture: Basics of modern first-order theorem proving
