ABSTRACT

In recent years, our society is being plagued by unprecedented levels of privacy and security breaches. To rein in this trend, the European Union, in 2018, introduced a comprehensive legislation called the General Data Protection Regulation (GDPR). In this article, we review GDPR from a system design perspective, and identify how its regulations conflict with the design, architecture, and operation of modern systems. We illustrate these conflicts via seven GDPR anti-patterns: storing data forever; reusing data indiscriminately; creating walled gardens and black markets; risk-agnostic data processing; hiding data breaches; making unexplainable decisions; treating security as a secondary goal. Our findings reveal a deep-rooted tussle between GDPR requirements and how modern systems have evolved. We believe that achieving compliance requires comprehensive, ground-up solutions, and anything short would amount to fixing a leaky faucet in a sinking ship.

1 INTRODUCTION

Modern computing systems exhibit unprecedented levels of scalability, reliability, and affordability. For example, Amazon’s cloud computing infrastructure provides on-demand access to inexpensive computing to over 1 million users in 190 countries, all the while guaranteeing four nines of availability. Similarly, Google operates 8 global-scale applications at 99.99% uptime with each of them supporting more than 1 billion users. As Internet-era systems focus on performance, cost-efficiency, reliability, and scalability as their primary design goals, security and privacy have taken a backseat.

However, it was not until recently that we realized the impact of relegating data security and user privacy as afterthoughts in system design. In 2013, Yahoo! experienced a theft of 3 billion user records; in 2016, Facebook had its user data illegally harvested to influence the U.S. and U.K. democratic processes; equally worse, it was discovered that many companies were indiscriminately collecting and using personal data without people’s consent. In response to these developments, the European Union (EU) adopted a privacy regulation called the General Data Protection Regulation (GDPR) [26]. By defining the privacy of personal data as a fundamental right of all European people, GDPR regulates the lifecycle of personal data. Thus, any company dealing with EU customers is legally bound to comply with GDPR.

In this work, based on our ongoing research [30], we examine how GDPR affects the design and operation of modern computing systems. Surprisingly, our analysis reveals that several design principles and architectural elements of real-world systems are at odds with the proposed regulation. We highlight seven such principles and practices, namely the GDPR anti-patterns, by discussing how they came to be, reviewing the conflicting regulation, and chronicling their real-world implications. For example, given the commercial value of personal data, modern systems naturally evolved to store them forever, to reuse them across various applications, to sell them for profit, and to stash them in walled gardens. However, GDPR either explicitly forbids or severely restricts the scope of all these practices.

The goal of this article is three folds: first, we provide a brief primer on GDPR (§2). Next, we illustrate the tussle between GDPR requirements and modern systems (§3). Finally, we shed light on the challenges of retrofitting existing systems into compliance (§4).

2 GDPR

On May 25th 2018, the European parliament adopted the General Data Protection Regulation [26]. In contrast with targeted privacy regulations like HIPAA [2] and FERPA [1], GDPR takes a comprehensive view by defining personal data to be any information relating to an identifiable natural person. GDPR defines three entities that interact with personal data: (i) data subject, the person whose personal data is collected, (ii) data controller, the entity that collects and uses personal data, and (iii) data processor, the entity that processes personal data on behalf of a data controller. Then, GDPR designates supervisory authorities to oversee that the rights and responsibilities of GDPR are complied with.

Figure-1 represents how GDPR entities interact with each other in collecting, storing, processing, securing, and sharing personal data. Consider the music streaming company Spotify collecting its customer’s listening history, and then using Google cloud’s services to identify new recommendations for customers. In this scenario, Spotify is the data controller...
and Google Cloud is the data processor. Spotify could also engage with other data controllers, say SoundCloud to gather additional personal data of their customers.

To ensure privacy and protection of personal data in such ecosystems, GDPR grants new rights to customers and assigns responsibilities to controllers and processors. Now, any person can request a controller—whether or not their personal data was directly obtained—to grant access to all their data, to rectify errors, to request deletion, to object to their data being used for specific purposes, and to port their data to third parties. On the other hand, the controller is required to obtain people’s consent before using their personal data, to notify them of data breaches within 72 hours of finding out, and to maintain records of activities performed on personal data. For controllers failing to comply with these rights and responsibilities, GDPR regulators could levy penalties of up to €20M or 4% of their annual global revenue.

Structure. GDPR is organized as 99 articles that describe its legal requirements, and 173 recitals that provide additional context and clarifications to these articles. The first 11 articles layout the principles of data privacy; articles 12-23 establish the rights of the people; then articles 24-50 mandate the responsibilities of the data controllers and processors; the next 26 articles describe the role and tasks of supervisory authorities; and the remainder of the articles cover liabilities, penalties and specific situations. We expand on the relevant articles in §3.

Impact. Compliance with GDPR has been a challenge for technology companies. A number of companies like Instapaper, Klout, and Unroll.me terminated their services in Europe to avoid the hassles of compliance. Few other businesses made temporary modifications. For example, media site USA Today turned off all advertisements [32], whereas the New York Times stopped serving personalized ads [15]. While most organizations are working towards compliance, Gartner reports [16] that less than 50% of the companies affected by GDPR were compliant by the end of 2018. This challenge is further exacerbated by the performance impact that GDPR-compliance imposes on current systems [29].

In contrast, people have been enthusiastically exercising their newfound rights, and not been shy to report any shortcomings. In fact, the EU data protection board reports [10] having received 94622 complaints from individuals and organizations in the first 9 months of GDPR. Surprisingly, even the companies have been forthcoming in reporting their security failures and data breaches, with 64684 breach notifications sent to regulators in the same 9 month period.

3 GDPR ANTI-PATTERNS

Many of the design principles, architectural components, and operational practices of modern computing systems conflict with the rights and responsibilities laid out in GDPR. We present seven such anti-patterns below, and summarize them in Table-1.
### 3.1 Storing Data Forever

Computing systems have always relied on insights derived from data. However, this dependence is reaching new heights, especially in this decade, with widespread adoption of machine learning and big data analytics in system design. Data has been compared to oil, electricity, gold, and even bacon [8]. Naturally, technology companies evolved to not only collect user data aggressively but also to preserve them forever. However, GDPR mandates that no data lives forever.

**Article 17: Right to be forgotten.** “(1) The data subject shall have the right to obtain from the controller the erasure of personal data without undue delay [ ... ]”

**Article 13: Information to be provided where personal data are collected from the data subject.** “(2)(a) [...] the controller shall provide the period for which the personal data will be stored, or the criteria used to determine that period;”

**Article 5(1)(e): Storage limitation.** “[... ] kept for no longer than is necessary for the purposes for which the personal data are processed [ ... ]”

GDPR grants users an unconditional right, via article 17, to request their personal data be removed from everywhere in the system within a reasonable time. In conjunction with this, articles 5 and 13 lay out additional responsibilities for the data controller: (i) at the point of collection, users should be informed the time period for which their personal data would be stored, and (ii) if the personal data is no longer necessary for the purpose for which it was collected, then it should be deleted. These simply mean that all personal data should have a time-to-live (TTL) that users are aware of, and that controllers honor. However, this restriction does not apply to archiving in the public interest, or for scientific or historical research purposes.

**Deletion in the real-world.** While conceptually clear, a timely and guaranteed removal of data is challenging in practice. For example, Google cloud describes the deletion of customer data as an iterative process [4] that could take up to 180 days to fully complete. This is because, for performance, reliability, and scalability reasons, parts of data gets replicated in various storage subsystems like memory, cache, disks, tapes, and network storage; multiple copies of data is saved in redundant backups and geographically distributed datacenters. Such practices not only delay the timeliness of deletions but also make it harder to guarantee it.

### 3.2 Reusing Data Indiscriminately

While designing software systems, a purpose is typically associated with programs and models, whereas data is viewed as a helper resource that serves these high-level entities in accomplishing their goals. This portrayal of data as an inert entity allows it to be used freely and fungibly across various systems. For example, this has enabled organizations like Google and Amazon to collect user data once, and use it to personalize their experiences across several services. However, GDPR regulations prohibit this practice.

---

</table>
As we are in the early days of large-scale commoditization of personal data, the norms for acquiring, sharing, and reselling them are not yet well established. This has led to uncertainties for people and a tussle for control over data amongst controllers. People are concerned about vendor lock-ins, and about a lack of visibility once their data is resold or shared in secondary markets. Organizations have responded to this by setting up walled gardens, and making secondary markets the behavior in secondary markets. It requires that anyone indirectly procuring personal data must inform the users, within a month, about (i) how they acquired it, (ii) how long would they be stored, (iii) what purpose would they be used for, and (iv) who they intend to share it with. The data trail set up by this regulation should bring the control and clarity back to the people.

Data movement in the real-world. When GDPR went live, a large number of companies rolled out data download tools for EU users. For example, Google Takeout lets users not only access all their personal data in their system but also port data directly to external services. However, the impact has been less savory for programmatic ad exchanges in Europe, many of which had to shut down. This was primarily due to Google and Facebook restricting access to their platforms for those ad exchanges, which could not verify the legality of the personal data they possessed.

### 3.4 Risk-Agnostic Data Processing

Modern technology companies face the challenge of creating and managing increasingly complex software systems in an environment that demands rapid innovation. This has led to a practice, especially in the Internet-era companies, of prioritizing speed over correctness; and to a belief that unless you are breaking stuff, you are not moving fast enough. However, GDPR explicitly restricts this approach when dealing with personal data.

Article 20: Right to data portability. "(1) The data subject shall have the right to receive the personal data concerning him or her, which he or she has provided to a controller. (2) [...] the right to have the personal data transmitted directly from one controller to another."

Article 14: Information to be provided where personal data have not been obtained from the data subject. "(1) (c) the purposes of the processing [...], (e) the recipients [...], (2) (a) the period for which the personal data will be stored [...], (f) from which source the personal data originate [...]. (3) The controller shall provide the information at the latest within one month."

With article 20, people have a right to request for all the personal data that a controller has collected directly from them. Not only that, they could also ask the controller to directly transmit all such personal data to a different controller. While that tackles the vendor lock-ins, article 14 regulates the behavior in secondary markets. It requires that anyone indirectly procuring personal data must inform the users, within a month, about (i) how they acquired it, (ii) how long would they be stored, (iii) what purpose would they be used for, and (iv) who they intend to share it with. The data trail set up by this regulation should bring the control and clarity back to the people.

### 3.3 Walled Gardens and Black Markets

As we are in the early days of large-scale commoditization of personal data, the norms for acquiring, sharing, and reselling them are not yet well established. This has led to uncertainties for people and a tussle for control over data amongst controllers. People are concerned about vendor lock-ins, and about a lack of visibility once their data is resold or shared in the secondary markets. Organizations have responded to this by setting up walled gardens, and making secondary markets more opaque. However, GDPR dismantles such practices.

Article 6: Lawfulness of processing. "(1)(a) Processing shall be lawful only if [...] the data subject has given consent to the processing of his or her personal data for one or more specific purposes."

Article 21: Right to object. "(1) The data subject shall have the right to object at any time to processing of personal data concerning him or her [...]"

The first two articles establish that personal data could only be collected for specific purposes and not be used for anything else. Then, article 21 grants users a right to object, at any time, to their personal data being used for any purpose including marketing, scientific research, historical archiving, or profiling. Together, these articles require each personal data item to have its own blacklisted and whitelisted purposes that could be changed over time.

Purpose in the real-world. The impact of the purpose requirement has been swift and consequential. For example, in January 2019, the French data protection commission fined Google €50M for not having a legal basis for their ads personalization. Specifically, the ruling said that the user consent obtained by Google was not “specific” enough, and the personal data thus obtained should not have been used across 20 services.

3.3 Walled Gardens and Black Markets

As we are in the early days of large-scale commoditization of personal data, the norms for acquiring, sharing, and reselling them are not yet well established. This has led to uncertainties for people and a tussle for control over data amongst controllers. People are concerned about vendor lock-ins, and about a lack of visibility once their data is resold or shared in the secondary markets. Organizations have responded to this by setting up walled gardens, and making secondary markets more opaque. However, GDPR dismantles such practices.

Article 20: Right to data portability. “(1) The data subject shall have the right to receive the personal data concerning him or her, which he or she has provided to a controller. (2) [...] the right to have the personal data transmitted directly from one controller to another.”

Article 14: Information to be provided where personal data have not been obtained from the data subject. “(1) (c) the purposes of the processing [...], (e) the recipients [...], (2) (a) the period for which the personal data will be stored [...], (f) from which source the personal data originate [...]. (3) The controller shall provide the information at the latest within one month.”

With article 20, people have a right to request for all the personal data that a controller has collected directly from them. Not only that, they could also ask the controller to directly transmit all such personal data to a different controller. While that tackles the vendor lock-ins, article 14 regulates the behavior in secondary markets. It requires that anyone indirectly procuring personal data must inform the users, within a month, about (i) how they acquired it, (ii) how long would they be stored, (iii) what purpose would they be used for, and (iv) who they intend to share it with. The data trail set up by this regulation should bring the control and clarity back to the people.

Data movement in the real-world. When GDPR went live, a large number of companies rolled out data download tools for EU users. For example, Google Takeout lets users not only access all their personal data in their system but also port data directly to external services. However, the impact has been less savory for programmatic ad exchanges in Europe, many of which had to shut down. This was primarily due to Google and Facebook restricting access to their platforms for those ad exchanges, which could not verify the legality of the personal data they possessed.

3.4 Risk-Agnostic Data Processing

Modern technology companies face the challenge of creating and managing increasingly complex software systems in an environment that demands rapid innovation. This has led to a practice, especially in the Internet-era companies, of prioritizing speed over correctness; and to a belief that unless you are breaking stuff, you are not moving fast enough. However, GDPR explicitly restricts this approach when dealing with personal data.

Article 35: Data protection impact assessment. “(1) Where processing, in particular using new technologies, is likely to result in a high risk to the rights and freedoms of natural persons, the controller shall, prior to the processing, carry out an assessment of the impact of the envisaged processing operations on the protection of personal data.”

Article 36: Prior consultation. “(1) The controller shall consult the supervisory authority prior to processing where [...] that would result in a high risk in the absence of measures taken by the controller to mitigate the risk.”
GDPR establishes, via articles 35 and 36, two levels of checks for introducing new technologies and for modifying existing systems, if they process large amounts of personal data. The first level is internal to the controller, where an impact assessment must analyze the nature and scope of the risks, and then propose the safeguards needed to mitigate them. Next, if the risks are systemic in nature or concern common platforms, either internal and external, the data protection officer must consult with the supervisory authority prior to any processing.

**Fast and broken in the real-world.** Facebook, despite having moved away from the aforementioned motto, has continued to be plagued by it. In 2018, it revealed two major breaches: first, that their APIs allowed Cambridge Analytica to illicitly harvest [31] personal data from 87M users, and then their new View As feature was exploited [28] to gain control over 50M user accounts. However, this practice of prioritizing speed over security is not limited to one organization. For example, in Nov 2017, fitness app Strava released an athlete motivation tool called global heatmap [27] that visualized athletic activities of worldwide users. However, within months, these maps were used to identify undisclosed military bases and covert security operations [24], jeopardizing missions and lives of soldiers.

### 3.5 Hiding Data Breaches

The notion that one is *innocent until proven guilty* predates all computer systems. As a legal principle, it dates back to the 6th century Roman empire [11], where it was codified that *proof lies on him who asserts, not on him who denies*. Thus, in the event of a data breach or a privacy violation, organizations typically claim innocence and ignorance, and seek to be absolved of their responsibilities. However, GDPR makes such presumption conditional on the controller proactively implementing risk-appropriate security measures (i.e., accountability), and notifying breaches in a timely fashion (i.e., transparency).

**Article 5: Principles relating to processing.** “(1) Personal data shall be processed with […] lawfulness, fairness and transparency; […] purpose limitation; […] data minimisation; […] accuracy; […] storage limitation; […] integrity and confidentiality. (2) The controller shall be responsible for, and be able to demonstrate compliance with (1).”

**Article 33: Notification of a personal data breach.** “(1) the controller shall without undue delay and not later than 72 hours after having become aware of it, notify the supervisory authority. […] (3) The notification shall at least describe the nature of the personal breach, […] likely consequences, and […] measures taken to mitigate its adverse effects.”

GDPR’s goal is two folds: first, to reduce the frequency and impact of data breaches, article 5 lays out several ground rules. The controllers are not only expected to adhere to these internally but also be able to demonstrate their compliance externally. Second, to bring transparency in handling data breaches, articles 33 and 34 mandate a 72 hour notification window within which the controller should inform both the supervisory authority and the affected people.

**Data breaches in the real-world.** In recent years, responses to personal data breaches have been ad hoc: while a few organizations have been forthcoming, others have chosen to refute [? ], delay [18] or even pay off hackers [19]. However, GDPR’s impact has been swift and clear. Just in the first 8 months (May 2018 to Jan 2019), regulators have received 41,502 data breach notifications [10]. This number is in stark contrast from the pre-GDPR era, with reports [33] of 945 worldwide data breaches in the first half of 2018.

### 3.6 Making Unexplainable Decisions

Algorithmic decision-making has been successfully applied to several domains: curating media content, managing industrial operations, trading financial instruments, personalizing advertisements, and even combating fake news. Their inherent efficiency and scalability (with no human in the loop) has made them a necessity in modern system design. However, GDPR takes a cautious view of this trend.

**Article 15: Right of access by the data subject.** “(1) The data subject shall have the right to obtain from the controller […] meaningful information about the logic involved, as well as the significance and the envisaged consequences of such processing.”

On one hand, privacy researchers from Oxford postulate [17] that these two regulations, together with recital 71, establish a “right to explanation” and thus, human interpretability should be a design consideration for machine learning and artificial intelligence systems. However, another group at Oxford argues [35] that GDPR falls short of mandating this right by requiring users (i) to demonstrate significant consequences, (ii) to seek explanation only after a decision has been made, and (iii) to have to opt out explicitly.

**Decision-making in the real-world.** The debate over the privacy and interpretability in automated decision-making
has just begun. Starting 2016, the machine learning and intelligence community began exploring this rigorously: the workshop on Explainable AI [7] at IJCAI, and the workshop on Human Interpretability in Machine Learning [20] at ICML being two such efforts. In January 2019, privacy advocacy group NoYB has filed [22] complaints against 8 streaming services including Amazon, Apple Music, Netflix, SoundCloud, Spotify, YouTube, Filmmit and DAZN for violating article 15 requirements in their recommendation systems.

3.7 Security as a Secondary Goal

The functionality-first approach is not specific to modern computing systems, rather it permeates through much of the computing history. For example, the Internet, which forms the foundation for cloud computing, was never designed with security in mind. It also illustrates the difficulties of retrofitting a functional system with afterthought security. Combating this practice is one of the central tenets of GDPR.

**Article 25: Data protection by design and by default.** "(1) [...] design to implement data-protection principles in an effective manner. (2) [...] ensure that by default, only personal data which are necessary for each specific purpose are processed, and [...] personal data are not made accessible to an indefinite number of persons.”

**Article 24: Responsibility of the controller.** “the controller shall implement appropriate technical and organisational measures to ensure, and to be able to demonstrate that processing is performed in accordance with this Regulation.”

**Article 28: Processor.** “the controller shall use only processors providing sufficient guarantees that [...] will meet the requirements of this Regulation.”

Together, these articles set the guidelines for security and privacy in a GDPR world. First, article 25 specifies that all systems must be designed, configured, and administered with data protection as a primary goal. Then, article 24 establishes that the ultimate responsibility for the security of all personal data lies with the controller. Lastly, article 28 precludes the controllers from using any processors (in our context, cloud providers) who do not meet the requirements of GDPR.

**Security in the real-world.** Cloud providers, who act as processors, have been swift in showcasing [25, 36, 37] the compliance of their service offerings. However, given the monetary and technical challenges in redesigning the existing systems, many organizations are turning to reactive security. This is evident in Amazon’s latest security offering, Macie [3], which employs machine learning techniques to automatically discover, monitor, and protect personally identifiable information on behalf of legacy cloud applications.

4 CONCLUDING REMARKS

Achieving compliance with GDPR, while necessary, is not trivial. In this paper, we examine how GDPR regulations conflict with the design, architecture, and operation of modern, cloud computing systems. Specifically, we illustrate this tussle via seven GDPR anti-patterns. The goal of our work is to highlight the challenges that existing systems face in achieving GDPR compliance. Given the importance of personal data, and the implications of misusing them, we believe that system designers should examine their systems for these anti-patterns, and work towards achieving GDPR-compliance with urgency.

**Open issues.** While our exposition focuses on seven systematic violations of privacy and security, there are many other unsavory practices that we have not covered. For example, the design and operation of online behavioral tracking [21]. Nor have we prescribed any policies or mechanisms towards achieving compliance. Also, the seven anti-patterns highlighted here exist due to technical and economical reasons that may not entirely be in the control of individual companies. Thus, solving such deep rooted issues would likely result in significant performance overheads, slower product rollouts, and reorganization of data markets. The equilibrium point of these tussles are not yet clear.

**Future directions.** GDPR compliance brings several interesting challenges to system designers. For example, addressing compliance at the level of individual infrastructure components (i.e., compute, storage, and networking) versus at the level of individual regulations will result in different tradeoffs. While the former makes the effort more contained (and suits the cloud model better), the latter provides opportunities for cross-layer optimizations (e.g., avoiding access control in multiple layers).

Another challenge arises from GDPR being vague in its technical specifications (possibly to allow for technological advancements). Thus, questions like how soon after a delete request should that data be actually deleted could be answered in several compliant ways. The idea that compliance could be a spectrum, instead of a well-defined point gives rise to interesting system tradeoffs as well as the need for benchmarks that quantify a given system’s compliance behavior.

While GDPR is the first comprehensive privacy legislation in the world, several governments are actively drafting their own privacy regulations. For instance, California’a Consumer Privacy Act (CCPA) [3], which goes into effect on Jan 1, 2020, and India’s ongoing Personal Data Protection bill [23]. We hope that this paper helps all the stakeholders in avoiding the pitfalls in designing and operating GDPR-compliant personal-data processing systems.
REFERENCES
