# Non-linear Motion

Elements of Graphics  
CS324e

---

---

# Interpolation

---

- ❖ Linear interpolation is a simple form of interpolation
  - ❖ Can only move along a line
  - ❖ Distance traveled between steps is constant
- ❖ Cosine interpolation provides smooth curves between points, but it does not allow for “true” continuity

# What is Continuity?

- ❖ Defines level of smoothness along a curve
- ❖ Types of continuity:
  - ❖ C0: curves are joined
  - ❖ C1: first derivatives of curves are continuous
  - ❖ C2: second derivatives of curves are continuous

(Wikipedia)

---

# Higher Continuity

---

- ❖ Higher-order continuities have advantages in both geometric modeling and in animation
- ❖ Some overhead, since additional points of data are required
- ❖ Splines are piecewise polynomials (multiple, connected lower-degree polynomial functions) with high continuity

---

# Quadratic Bezier Curve

---

---

# Question

---

- ❖ How does the quadratic Bezier curve interpolate between points?

# Cubic Bezier Curve

---

# Question

---

- ❖ How does the cubic Bezier curve interpolate between points?

---

# Combining Bezier Curves

---

Bezier curves can be joined to form a B-spline!

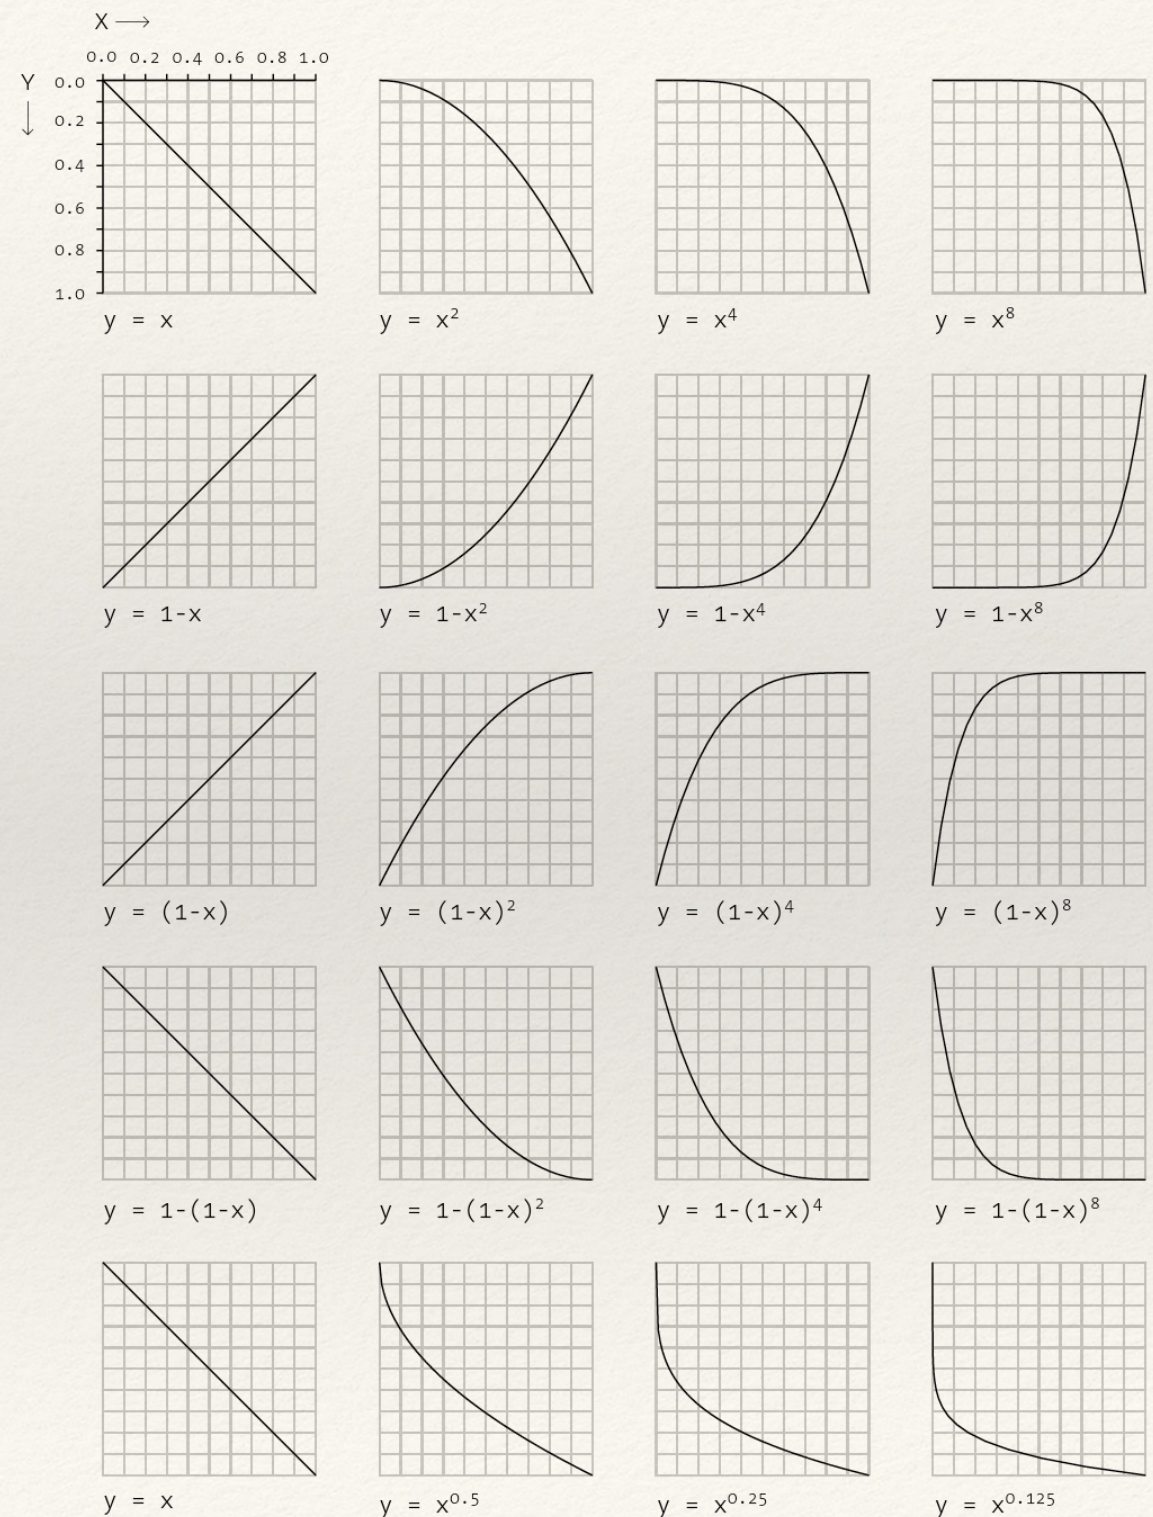

Sequence of Bezier curves and control points that form a B-spline (Wikipedia)

# Other Interpolation Functions

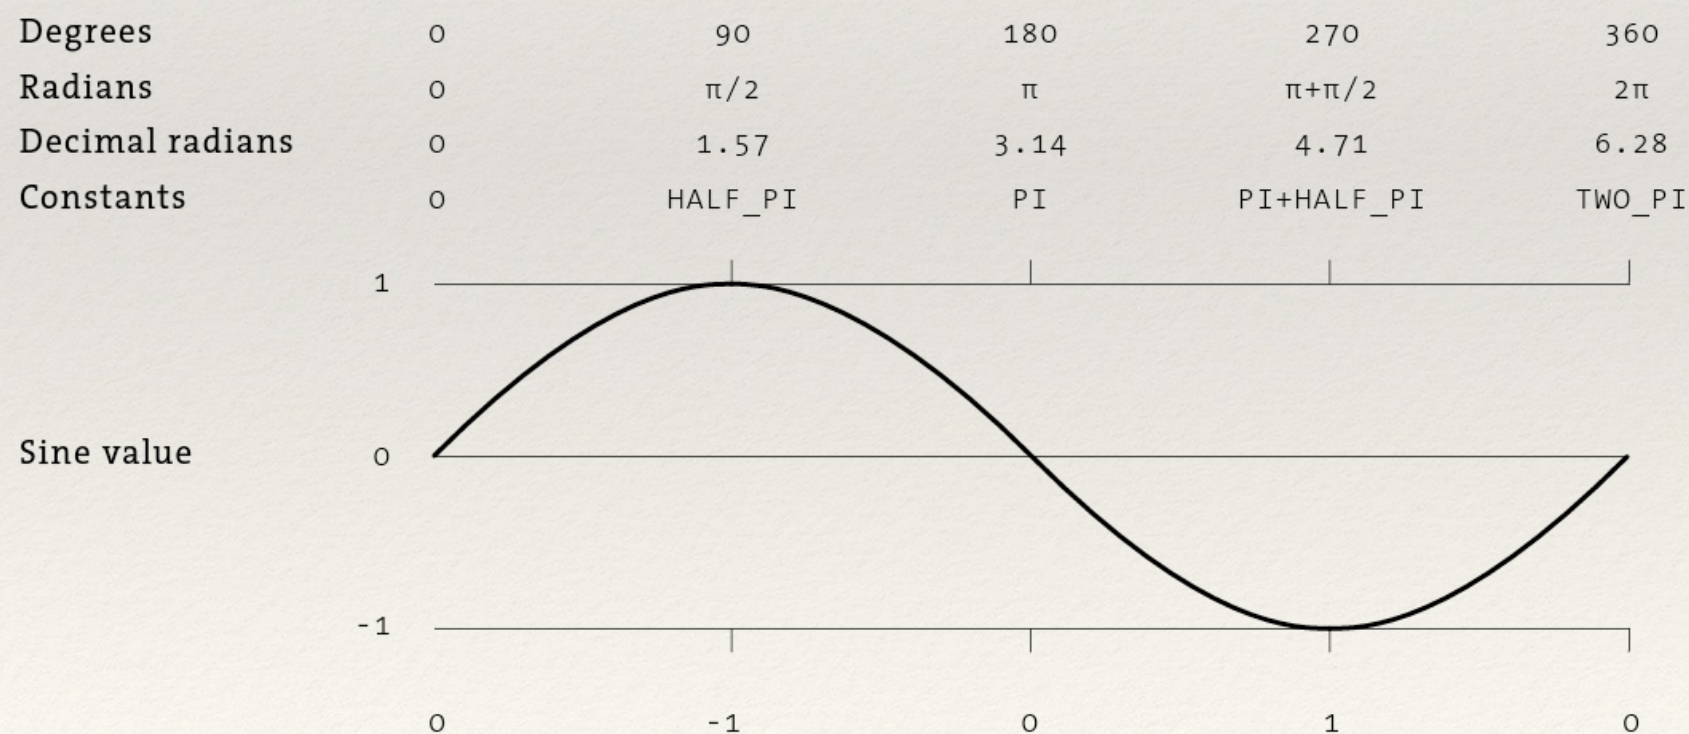

- ❖ Interpolation calculates intermediate values between targets
- ❖ Interpolation along arbitrary functions generates a range of behaviors

# Sine Waves

- ❖ Sine (and cosine) equations model a periodic relationship between radians and sine / cosine value
- ❖ Sine waves have an angle ( $\Theta$ ), amplitude ( $a$ ) and phase ( $p$ )

---

# Using Sine

---

- ❖  $\sin(\Theta)$  outputs a value between -1 and 1 based on  $\Theta$  (between 0 and  $2\pi$ )
- ❖ Amplitude  $a$  magnifies the value of the sine peak
- ❖ Phase  $p$  controls where the oscillation cycle begins
- ❖ Sine can control rate of motion (frequency) as well as direction of motion

---

# Question

---

- ❖ If  $\sin(\Theta)$  and  $\cos(\Theta)$  are applied to the x and y position of an object respectively, what will that object's motion be?

---

# Easing

---

- ❖ Easing allows movement between two values at nonlinear increments
- ❖ Objects can accelerate / decelerate as they approach the target
- ❖ Equation determines the fraction of the distance between the object's current and target positions that the object moves

---

# Ease-out Example

---

```
float x = 0.0;
float easing = 0.05;
float targetX = 400;
void setup() {size(500, 500);}
void draw() {
    x += (targetX - x) * easing;
    ellipse(x, 250, 50, 50);
}
```

# Ease-out as a Function

- ❖ We can also think of ease-out as a *lerp* operation over non-even time increments

---

# Types of Ease Functions

---

- ❖ Robert Penner defined a range of easing equations:  
<http://gizma.com/easing/>
- ❖ These equations are based on change in value over time
  - ❖ Ease in
  - ❖ Ease out
  - ❖ Ease in/out
- ❖ Basic functions are linear, quadratic, cubic, quartic and quintic equations

The graphics featured here represent the *transitions* that can be used on calls to Tweener's `addTween()` and `addCalller()` methods to create different easing effects on animations. They are based on Robert Penner's original easing equations. The `linear` transition (seen to the left) is what you would expect of a normal tweening (with no easing at all). The rest of the options have varying easing curves. The default on Tweener is `easeOutExpo`.

---

# Hands-on: Using Non-linear Motion

---

❖ Today's activities:

1. Use  $\sin(\Theta)$  to oscillate a ball back and forth from a point
2. Now use  $\sin(\Theta)$  to circle a ball around a point
3. Rewrite the ease-out function using the `lerp` method
4. Create an ease-in function using the `lerp` method.  
Note that you will need to track the total distance between start and end position as well as the current distance to the end position to do this
