**LEVEL OF DETAIL**

## LEVEL OF DETAIL (LOD)

- ▶ When an object is close to the viewer, we want a high resolution model
  - ▶ Thousands of polygons in high-res textures
- ▶ When an object is a long way away, it maps to relatively few screen pixels, so we want a low resolution model
  - ▶ Maybe only a single polygon, or tens of polygons
- ▶ Level of Detail (LOD) techniques draw models at different resolutions depending on their relevance to the viewer
  - ▶ Covers both the generation of the models and how they are displayed
  - ▶ Deep topic, this is just an overview

# LOD MODELS AT FULL RESOLUTION

# LOD MODELS AT SCALE

## STANDARD LOD

- ▶ The current standard for LOD in games is to use a finite set of models
  - ▶ Typically aim for models with  $n$ ,  $n/2$ ,  $n/4$ , ... polygons
  - ▶ Models may be hand generated or come from automatic decimation of the base mesh (highest resolution)
- ▶ Models are switched based on the distance from the object to the viewer, or projected screen size
  - ▶ Better metric is visual importance, but it is harder to implement
  - ▶ Objects that the viewer is likely to be looking at have higher resolution, objects at periphery have lower resolution

## EXAMPLES

- ▶ No Man's Sky <[https://youtu.be/WrsLdwm\\_40k?t=209](https://youtu.be/WrsLdwm_40k?t=209)>
- ▶ Final Fantasy XV <<https://youtu.be/TbKkJKfy6Cg?t=30>>

# MESH DECIMATION

- ▶ Take a high resolution base mesh and approximate it while retaining its visual appearance
- ▶ Desirable properties:
  - ▶ Fast (although not real-time)
  - ▶ Generates “good” approximations
  - ▶ Handles wide variety of input meshes
  - ▶ Allows for geomorphs (geometric blending from one mesh to another)
- ▶ Two essential questions:
  - ▶ What operations are used to reduce the mesh complexity?
  - ▶ How is “good” measured and used to guide the approximation?

# MESH OPERATIONS

- ▶ Operations seek to eliminate triangles while maintaining appearance. Key questions:
- ▶ What does the operation do?
  - ▶ Can it connect previously unconnected parts of the mesh?
  - ▶ Does it change the mesh topology?
- ▶ How much does it assume about the mesh structure?
  - ▶ Must the mesh be manifold (locally isomorphic to a disc)?
  - ▶ Can it handle, or does it produce, degenerate meshes?
- ▶ Can it be construed as a morph?
  - ▶ Can it be animated smoothly?

# VERTEX CLUSTERING

- ▶ Partition space into cells
  - ▶ Grids [Rossignac-Borrel], spheres [Low-Tan], octrees, etc
- ▶ Merge all vertices within the same cell
  - ▶ Triangles with multiple corners in one cell will degenerate

(Michael Garland, <http://graphics.cs.uiuc.edu/~garland>)

# VERTEX DECIMATION

- ▶ Iteratively on original model:
  1. Rank vertices according to their importance
  2. Select unimportant vertex, remove it, re-triangulate hole
- ▶ Fairly common technique
  - ▶ Schroeder et al, Soucy et al, Klein et al, Ciampalini et al

(Michael Garland, <http://graphics.cs.uiuc.edu/~garland>)

## VERTEX PAIR CONTRACTION

- ▶ Can contract any pair of vertices
  - ▶ Fundamental operation is exactly the same
  - ▶ Joins previously unconnected areas
  - ▶ Achieves topological simplification

(Michael Garland, <http://graphics.cs.uiuc.edu/~garland>)

## EDGE CONTRACTION

- ▶ Single edge contraction  $(v_1, v_2) \rightarrow v'$  is performed by
  1. Move  $v_1$  and  $v_2$  to position  $v'$
  2. Replace all occurrences of  $v_2$  with  $v_1$
  3. Remove  $v_2$  and all degenerate triangles

# ITERATIVE CONTRACTION

- ▶ Contraction can operate on any set of vertices
  - ▶ Edges (or vertex pairs) are most common, faces also used
- ▶ Iterate on original model:
  1. Rank all edges with some cost metric
  2. Contract minimum cost edge
  3. Update edge costs

(Michael Garland, <http://graphics.cs.uiuc.edu/~garland>)

## OPERATIONS TO ALGORITHMS

- ▶ A single operation doesn't reduce a mesh!
- ▶ Most common approach is a greedy algorithm built on edge contractions (iterative edge contractions):
  1. Rank each possible edge contraction according to how much error it would introduce
  2. Contract edge that introduces the least error
  3. Repeat until done
- ▶ Does NOT produce optimal meshes
  - ▶ An optimal mesh for a given target number of triangles is the one with the lowest error with respect to the original mesh
  - ▶ Finding the optimal mesh is NP-hard (intractable)

## ERROR METRICS

- ▶ Error metric measures error introduced contracting an edge
  - ▶ Low for edges whose removal leaves mesh mostly unchanged
- ▶ Issues:
  - ▶ How well does it measure changes in appearance?
  - ▶ How easy is it to compute?
  - ▶ Can it handle color and other non-geometric attributes?
  - ▶ Error is measured with respect to original mesh

## MEASURING ERROR WITH PLANES

- ▶ An edge contraction moves two vertices to a single new location
- ▶ Measure how far this location is from the planes of the original faces
- ▶ 2D examples (planes are lines):

- ▶ Error  $\equiv$  sum of squared distances to planes associated with vertex

## SAMPLE MODEL: DENTAL MOLD

424,376 faces

60,000 faces

## SAMPLE MODEL: DENTAL MOLD

424,376 faces

55 sec

8000 faces

## SAMPLE MODEL: DENTAL MOLD

424,376 faces

1000 faces

## SHOULD ALSO CONSIDER MESH ATTRIBUTES

Mesh for solution

Radiosity solution

## MUST ALSO CONSIDER ATTRIBUTES

- ▶ Add extra terms to plane equations for color information (or texture coords)
- ▶ Makes matrices and vectors bigger, but doesn't change overall approach

50,761 faces

10,000 faces

## LOD SWITCHING

- ▶ When should we switch between LODs?
- ▶ How should we switch between LODs?

# LOD SWITCHING

- ▶ Popping
  - ▶ Sudden change in appearance as models are swapped
  - ▶ If the object is at the switching distance, may flicker
- ▶ Popping Example:
  - ▶ Black Desert Online <<https://www.youtube.com/watch?v=0ShwKAuRxbc>>

## HOW TO HANDLE POPPING?

- ▶ Leave popping but try to avoid flicker
- ▶ Show a blended combination of two models, based on the distance between the switching points
  - ▶ Image blend – render two models at alpha 0.5 each
  - ▶ Geometric blend – define a way to geometrically morph from one model to the next, and blend the models
- ▶ Have more models that are so similar that the popping is not evident

## HYSTERESIS THRESHOLDS

- ▶ Avoid rapid popping if the object straddles the threshold for switching
- ▶ Define two thresholds for each switch, distance as the metric
  - ▶ One determines when to improve the quality of the model
  - ▶ Other determines when to reduce it
  - ▶ Reduction threshold should be at a greater distance than the increase threshold
- ▶ If the object is between the thresholds, use the same LOD as on the previous frame

## HYSTERESIS ILLUSTRATION

- ▶ Imagine an object repeatedly jumps from one position to a nearer one and then back again
  - ▶ How far must it jump to exhibit popping?
- ▶ One way to think about it: If you're on one level, you can only ride the arrows to the next level

# INDUSTRY LOD TOOL: SIMPLYGON

- ▶ Widely used automatic 3D optimization tool

- ▶ <http://www.gdcvault.com/play/1020666/Optimize-your-3D-Assets-with>
- ▶ <https://www.youtube.com/watch?v=Tzvw6Df5pnl>
